MONEY AND EXCHANGE

Commerce reports do not yet show the anticipated effect of foreign exchange depreciation, in diminishing the volume of our exports. As 'Boston News Bureau' points out, up to the end of January there had been no such decrease in our export totals, although the counter effect of a stimulus to imports had become fairly pronounced. It takes time for financial impediments to reach expression in cargo terms, and goods continue, for a considerable interval, to flow out on old orders. Likewise a shifting in character of sales may make good considerable losses in some respects. The February figures may tell a different story, inasmuch as actual freight conditions are known to have changed radically during that month.

January managed to set, at \$731,000,000, a new export record for that month, by a margin of \$108,000,000 over the former January high point in 1918. Aside from the exceptional peak of \$928,000,000 attained last June, it is within some \$10,000,000 of the former monthly high level, made last November. In the 15 months since the Armistice, a period during which a pronounced drop from wartime totals was predicted by many, the monthly export average has been \$650,000,000, with the largest records in the more recent months. In the prior 15 months of war the corresponding average was only \$512,000,000.

The destinations of some of our recently increased exports explain a good deal and also suggest some doubt of permanence in some of the new totals. One obvious reason for continued increase lies in the comparison of resumed, if still small, exports to the Teutonic alliance, as against nothing permitted under the blockade. Thus in 1919 our new sales to the Teutonic confederacy uniformly increased to such an extent that for the year they totaled almost \$190,000,000.

Still more conspicuous have been the recent gains in our sales to near neighbors of Germany during wartime, with several restricted. During 1919 our aggregate sales to Belgium, Denmark, Holland, Sweden, and Norway were no less than \$1,065,000,000, as against only \$230,000,000 in 1918. That huge increase meant the supplying of defenses, and naturally cannot be maintained. In fact, many warehouses in those countries are reported bulging now with unsold Yankee goods, shipped there during recent months.

January imports at \$474,000,000 set both a new record for that month by \$222,000,000 and a new record for any month by a margin of almost \$100,000,000 over last September. The manner in which imports have lately crept steadily upward has also been notable. In 1918 they varied little from an average of \$250,000,000 per month, and maintained that pace for the first third of 1919.

There is significance in the changing character of our commerce. In 1919 the proportion of crude materials for manufacturing exported rose to 20.78% of the total exports, getting as high as 33% in December. In 1917 the same percentage was only 12.65%. Conversely our sales of finished or partly finished manufactured goods have fallen from 65% to 45% of total exports between 1917 and 1919. Europe is buying disarmament with a view to future sales to us.

Foreign quotations on March 2 are as follows:

	Demand	7.03
Lire, cents:	Cable	5.49
	Demand	5.49
Marks, cents:	Cable	1.05
	Demand	1.05

Eastern Metal Market

New York, February 25.

The markets are generally more active, stronger, and higher.

Copper demand has improved somewhat but prices are unchanged. They are firm with a strong tone.

Tin prices have advanced with the betterment in exchange and in values in the London market.

Demand for lead continues to gather strength and prices are higher.

Buying of zinc has increased and inquiry is expanding with an advance in prices.

Antimony is quiet but steady.

IRON AND STEEL

The steel trade is now particularly interested in the extent of prospective buying by the railroads. Already the New York Central is inquiring for 150 locomotives and 13,200 box-cars and the Rock Island for 35 locomotives and 3250 cars. The Union Pacific has bought 102 locomotives and the St. Paul wants 100, while the Great Northern has ordered 1000 cars and the Soo Line 300.

Steel producers do not show yet much inclination to open their books for forward business, and in contrast to this may be cited a tendency here and there on the part of consumers to take their chances in waiting for lower prices. The decision of one prominent producer to sell for second quarter may signify the end of price advances, as these orders will be taken at 4c. for plates, shapes, and bars. There are signs that the bulk of third-quarter delivery purchases yet to be made will be at higher prices than are now the average, possibly \$2 per ton above war-level prices.

COPPER

Conditions have changed but little; but for the better. Demand is slightly better with a little more inquiry for electrolytic and some light business reported. There has also been some improvement in export demand and in export conditions in general. Electrolytic is quoted by most producers at 19c. to 19.12½c. for early or first-quarter delivery, with second-quarter held at 19.25c., New York. Lake is slightly stronger at 19.25c. to 19.37½c., New York. Second-quarter deliveries are about 1c. higher. Producers and sellers look forward confidently to better demand in the spring and summer both from domestic and foreign consumers.

TIN

The market here has steadily advanced until today spot Straits is quoted at 64c., New York, with futures held at around 65.50c. Transactions have been only moderate for any delivery and the business that has been done has been mostly between dealers. Another important factor in the advancing market here has been the spectacular advance in the London market. Tin has gone to over £100 per ton and yesterday reached £415 10s. for spot Straits with £418 for futures, the highest levels ever reached. The previous high level was £399 per ton last August. In the local market here, there appears to be less desire on the part of leading sellers to sell and the statistical position is growing stronger all the time with the metal concentrating in stronger hands, as noted a week ago. It is expected by some that the New York market will follow that of London from now on. For the first time in many months or even years, dealing in tin was reported last Friday on the New York Metal Exchange. Arrivals thus far this month have been 4395 tons, with the quantity afloat 3770 tons.

LEAD

Instead of production tending to overtake demand, as

predicted by a few some time ago, the opposite seems to be the tendency. Demand is heavier and prices are advancing. Yesterday the American Smelting & Refining Co. advanced its price from 8.75c. to 9c., New York, to which level the outside market had already risen late last week. We quote the outside market and the 'Trust' price as 8.75c., St. Louis, or 9c., New York, for early delivery, with the likelihood that the former will soon pass the latter. It is stated that the metal could be sold as high as 9.75c., for delivery in the second quarter and that inquiry is very good. Foreign demand is a factor also and may so continue, for the usual foreign supplies are not as plentiful as some years ago. In the last two weeks the London market has advanced £2 10s. per ton, or from £49 15s. to £52 5s. per ton.

ZINC

In the past week demand and buying has improved and the tone of the market is stronger and better. With the upward movement in exchange value, there appeared last week a buying movement of moderate proportions from foreign buyers, and fair quantities were sold on a scale upward from 8.75c. to 9c., St. Louis, for delivery into the second quarter. In the domestic market, galvanizers and brass-makers have been buyers for early delivery and today at least seven large galvanizers are inquiring for quantities ranging up to 400 tons, each for delivery during the second quarter. Quotations consequently have advanced steadily until today prime Western is quoted at a minimum of 9c., St. Louis, or 9.35c., New York, for early and second-quarter delivery.

ANTIMONY

The market is quiet and unchanged but strong with wholesale lots for early delivery quoted at 11.62½c., New York, duty paid.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted at \$1.50c. to 33c. in wholesale lots for early delivery, depending on whether bought from the leading interest or the outside market, the higher level applying to the former.

ORES

Tungsten: The decision of the tariff question is all absorbing just now and as a consequence the market is inactive and prices are nominal at \$6 to \$15 per unit, depending on the grade of ore and delivery. Ferro-tungsten is quoted in one case at 95c. to \$1 per pound of contained tungsten, but very little business is heard of.

Molybdenum: The market is quiet and prices are unchanged and nominal at 75c. per pound of MoS₃ in regular concentrates.

Manganese: The foreign ore mentioned a week or so ago as being offered at \$1 per unit is now obtainable at 80c., but no sales are recorded. The question of shipping is the important one and is apparently holding up deliveries. It is also calculated that at \$1 per unit, ferro-manganese producers could not break even at present prices, estimating 2½ tons of ore to 1 ton of alloy.

Manganese-Iron Alloys: Spot ferro-manganese is very scarce and much higher. Sales have been made at both \$200 and \$225, delivered, and demand for odd lots is insistent. Some consumers are hard put for supplies. British alloy is scarce with little available. Sales have been made for second quarter at \$65, seaboard. American producers are asking \$170 for third quarter, and \$160, delivered, for last half. Spiegeleisen is quiet but very strong at \$57 to \$60, furnace, the higher price holding for nearby deliveries.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

GASOLINE-ENGINE DRIVEN GENERATOR SETS

The requirements of the Army during the War brought particular emphasis to the fact that for certain work and conditions an independent portable source of power and light is desirable. Gasoline-engine driven generators of various sizes were employed extensively to great advantage.

The Allis-Chalmers Manufacturing Co. furnished a large number of these sets to the Government and their success in operation under the exacting conditions has thoroughly demonstrated their reliability as apparatus for general use.

Two sizes have recently been placed on the market: 5-kw., 110 or 220 volts, and 15-kw., 110 or 220 volts.

These sets employ four-cylinder, four-cycle gasoline en-

generator frames. A coupling on the generator shaft fits into a recess in the flywheel and is bolted rigidly to it. The flywheel and coupling are enclosed in the barrel housing. This construction gives a very compact arrangement and one in which the bearing alignment does not depend upon the rigidity of the base casting and foundation. In this set the gasoline-tank is mounted above the generators with gravity feed to the carburetor. The switchboard is mounted on angle irons attached to the base casting.

The 15-kw. set is in some respects different in construction from the 5-kw. set. The generator is provided with front and rear bearing-housings and is coupled to the engine by means of a flexible coupling. The gasoline-tank is rectangular in form and is mounted in the base under the engine. The gasoline is raised to the carburetor by means of a vacuum system similar to that widely used in automobile construction. In this set the switchboard is separately mounted and may be placed in any convenient position.

These sets make available a source of power and light which is flexible in application and comparatively cheap. Even in localities where electricity is available it will be found cheaper and more expedient in many cases to have an independent portable source of power and light. Central stations usually exact a charge for installing a meter and wiring and a minimum rate for electricity.

Concrete-mixers, hoists, centrifugal pumps, reciprocating pumps, air-compressors, and many other types of machinery can be economically and efficiently operated by electricity.

Without an independent portable source of electric power, the use of the most efficient electrically operated tools and equipment is impractical because of the uncertainty of being able to get electricity at all, because the voltage or frequency may be different in different places, and because of the delay and expense in getting meters and wiring from supply circuits installed.

5-kw., 110-volt Generator Driven by Gasoline Engine

gines of the automobile type, which are of ample size and rating to withstand continuous full-load service without being over-taxed. The engines will carry momentary overloads up to the ultimate capacity of generators without bringing undue mechanical strain on any of the working parts. They are equipped with standard magnetos, carburetors, water-circulating pumps, tubular-type radiators, and fans. Governors are provided which positively regulate the speed to within 4% of the set speed of the engine from no load to full load. The generators are provided with compound windings proportioned so that the voltage variations do not exceed 2% from the set voltage from no load to full load.

The 5-kw. set shown in the photograph has three main bearings; one being the standard ring-oiled generator bearing, the other two being in the frame of the engine. The generator is held in accurate alignment by a rigid barrel housing which is machined to fit shoulders on the motor and

FLEXIBLE SHAFTING

The Stow Manufacturing Co. of Binghamton, New York, builder of portable tools, is distributing a valuable booklet entitled 'Flexible Shaft'. A dozen special uses of flexible shafting are discussed and some general information regarding its manufacture and utility is given. The following is quoted from Bulletin No. 104:

"Flexible shafting consists essentially of an inner core constructed of built-up wire coils and a protecting casting with bearings and suitable fittings for the transmission of power from some source such as an electric motor, counter-shaft, or engine to the tool. The core in the shaft is brazed or soldered into end fittings, assembled in a reinforced leather or metal casing which supports the bearings, and is held in the case in such a way that when the shaft is bent no strain will come longitudinally on the core. This is very important, since the cores are not designed to resist end pull. The design of flexible shafts usually includes a sliding connection of some kind to take care of this feature.

"Flexible shafting does not compare with the solid shafting in the matter of strength, since this must be sacrificed

to obtain flexibility. The bearings must be constructed to withstand harder usage than those for solid shafts, due to the vibration which follows from the design and which cannot be eliminated. However, in spite of these disadvantages the flexible shaft finds many applications where the solid shaft could not be used. The standard shaft is designed to run clockwise and will transmit only two-thirds of its normal power when operated in the reverse direction. Shafts may be obtained, however, for left-hand operation. Keep flexible shafts and tools well oiled. The flexible shaft is a bearing for its entire length and should be treated accordingly. To oil, use unsalted tallow, lard oil, or animal oil. Never use mineral oil, especially when leather or fabric cover is used, as such oil has a tendency to rot it. When oiling, disassemble shaft, remove the core, and immerse in the lubricant, taking care not to subject the core to rough handling while out of its bearings. Examine the shaft thoroughly each day. Avoid sharp bends and support it as much as possible. If the shaft begins to buckle it is overloaded, and the only remedy is to relieve it at once."

A PERMANENT MACHINERY EXPOSITION AND SALES-CENTRE

By Howard R. Ward

The number of machinery manufacturers in the United States has increased largely in the last few years. Plants are now found in almost all sections of the country. Machinery has not only greatly increased in diversity, but a similar expansion has also taken place in the manufacture of appliances and supplies. The products of these manufacturers are sold not only in America but in most parts of the world.

Many channels are used to bring these products to the notice of prospective consumers: advertising in the trade journals which have become effective channels of information in their various fields; extensive use of technical salesmen; advertising in the popular journals; circularization; personal correspondence. The methods have in fact become so numerous and the market so wide that the manufacturer cannot take advantage of them all and finds it necessary to choose only certain fields and to limit his methods of reaching those fields.

The consumer is in much the same position. Formerly he was in close touch with the one or two concerns which were the only ones who could supply him with the machinery and supplies that he used in his business. Today in attempting to secure what is best suited to his needs, he must study all appropriate advertising mediums, he frequently travels extensively to visit manufacturing plants, and he must keep the data he collects in available shape, and up to date.

One possible solution of the increasingly difficult problem is to establish a permanent exposition and sales centre at a point as mutually convenient as possible for the manufacturer and for the domestic and foreign consumer. A sales-centre for machinery and kindred appliances and products, once permanently established in a proper location, would unquestionably be of value to both the manufacturer and the consumers. Though some attempts have been made that have resulted in failure, the reason has always been evident; either the scope was too limited or the location was not central or convenient. Some attempts have succeeded in foreign cities and also in this country, but in all cases their success or lack of success has been governed by their location and scope.

New York city has become more and more the logical place for a permanent sales-centre. It is visited regularly by manufacturers, operators, buyers, and engineers from all parts of the world. The Grand Central Palace, a twelve-story reinforced-concrete building, occupying an entire block,

is to become just such a sales-centre. Eight floors, each containing approximately 50,000 sq. ft. of floor space, are to be devoted to the permanent display of machinery, mechanical appliances, and all allied products. The lower floors will continue to be used as heretofore for short-term exhibitions such as the Chemical Exposition, Automobile Show, and the like. The location of this building, in the Grand Central zone, is ideal. It is within close reach of the railway terminals, the hotel district, and technical libraries.

This permanent exhibit will be known as the 'International Exposition of Industries', and its scope on mechanical lines will be extremely broad and comprehensive. Exhibits will include farm tractors and mining equipment, construction machinery, and other commodities. It will cover the widest possible range of mechanical devices. The mining section will include machinery and appliances for the production of coal, metals, minerals, and petroleum. In other sections will be found machinery and devices used in the various mining industries but not manufactured primarily for these fields.

In working out the details of the project the organizers have kept in mind certain important factors. It was realized that the cost of exhibiting should be kept as low as possible and that the service given the exhibitors should be worth more than the cost of exhibiting. The services usually found in all up-to-date office buildings will be available, and will include elevator service, janitor service, light, heat, and power. In addition to these services, attendants will be stationed on each floor. These attendants will be technical, practical, experienced men, able to explain to visitors the purpose and method of operation of the appliances exhibited. As a result of this service it will not be necessary for manufacturers to keep their own technical salesmen in attendance. When visitors are found to be in the market for immediate purchases they will be placed in touch with the manufacturers' salesman. The institution of this permanent exhibit and sales-centre in the Grand Central Palace will offer many advantages to exhibitors besides the benefit of a central point for exhibition, demonstration, and sale of their products. The great value of interchange of thought in industrial efforts is now well recognized and the 'International Exposition of Industries' will give this stimulus to manufacturers, engineers, operators, and consumers. It will not only bring direct benefits to producers and consumers, but will result in broadening and stimulating the fields and efforts of each industry.

COMMERCIAL PARAGRAPHS

Robert T. Banks, formerly of El Paso, is now Northwestern manager for the Sullivan Machinery Co. at Spokane, succeeding L. R. Chadwick, who has been placed in charge of the New York office of the same company.

The Traylor Engineering & Manufacturing Co. through its Los Angeles office has sold to the Burma Mines, Ltd., for shipment to India, five sets of 54 by 24 in. Traylor AA heavy-duty crushing-rolls, and one set of 36 by 14 in. rolls of similar type, as well as a steam-driven air-compressor and a complete 'cement-gun' outfit. The same office has also sold to the Mountain Copper Co. of California, two sets of 42 by 16 in. rolls.

During the past few years many articles have been written giving the history of the steam-turbine and describing its rapid advance from the experimental stage to its present position as one of the principle prime movers. The design and construction of the blading are of prime importance and the engineering and shop organizations of the Allis-Chalmers Manufacturing Co. have devoted much time and energy to this feature of construction. Bulletin No. 1104 is an instructive publication detailing the growth in the technique of the manufacture of these blades, and the improvements made to date.

T. A. RICKARD. . . . Editor

ON March 6 the Democratic party in California selected an unpledged delegation to the Democratic National Convention, after Messrs. McAdoo and Hoover had asked that the delegation be not pledged to them. Mr. Hoover advised the Democratic State Committee that he was "not a candidate". This, it will be presumed, means that he is not a candidate on the Democratic ticket and thereby confirms his reply to the Democrats in Georgia; moreover, in California a Presidential candidate cannot have a pledged delegation on more than one primary ballot. On page 383 we print the speech delivered by Mr. Hoover before the Western Society of Engineers on February 28.

DISTILLATION of shale-oil is a subject of growing importance; therefore the scholarly article by Mr. James A. Bishop, of Denver, will be welcomed by the numerous mine-operators that are now engaged in the exploitation of shale as a source of oil. The nature and qualities of the compounds obtained from kerogen, the substance that makes shale valuable for the purpose, are discussed by Mr. Bishop in terms of chemistry. He compares constructive with destructive distillation and describes the chemical and physical properties of the compounds derived therefrom; these distillates are of three grades, with possibly a fourth. By fractionating at successive temperatures there are yielded a variety of commercial products of diversified usefulness. Mr. Bishop shows the need for efficiency and tonnage in making the process of shale beneficiation profitable and gives technical data of a most timely character.

LESSENING of gold production in California, as well as elsewhere, is the subject of a circular issued by Mr. Fletcher Hamilton, the State Mineralogist. He refers to the need for more gold to sustain the vast structure of credits created by the War and the necessity for strengthening the standard upon which international values are based. The United States is the only country in which no premium on gold is obtainable, he says. In 1914 the consumption of gold in the arts was \$45,520,918; in 1919 this consumption increased to \$80,337,600, as against an output in this country of \$94,531,800 in 1914 and of only \$58,488,800 in 1919, so that the amount of gold used last year in the arts, and not available as standard money, exceeded our domestic production by \$21,848,800. To correct this anomalous condition and

to stimulate the search for ore, now retarded by the high cost of labor and supplies, Mr. Hamilton advocates the imposition of an excise tax on manufactured gold for the purpose of paying a premium upon newly produced gold.

FOUR mining companies at Tonopah have adopted a plan of 'blanket' life insurance for all employees of both mines and mills, without cost to the men themselves. Each company is to have a policy with one of the large Eastern life-insurance societies that will assure the family or other beneficiary of each miner or mill-man a definite sum in case of his death from any cause, so long as he is on the payroll of the company. This is distinct from, and in addition to, any compensation provided by the State law as administered by the Industrial Commission. No physical examination is required and the insurance applies without discrimination to every man who has been employed for a minimum period of two months until such time as his service with the mining company shall have been terminated. One important feature of the arrangement is the fixation of the amount of insurance on the basis of the length of time the individual has been continuously employed. Beginning with \$500, the amount increases in several steps so that after one year the beneficiary, in case of the employee's death, will receive \$1250; and after two years, \$1500. This method recognizes, and obviously will tend to decrease, the costly practice of changing continually from one mine to another or from one district to another, which has become a habit with Western miners. This excessive turn-over is expensive to the employee no less than to the employer, so that by supplying an incentive for regular work with one company the new scheme will be a mutual benefit.

A SUBSCRIBER from Surf Inlet, British Columbia, apropos of several recent articles on ball-mill operation, writes for information as to "the proper ball-load in the mill, which we mill-men here consider as important as the feed, in grinding ore". The principal factors that influence grinding operations in a given mill are the kind of lining, the speed of rotation, the size of the balls, and the load of balls in the mill; also the dilution of the feed, size of particles, and the hardness and toughness of the ore. The nature of the product desired is a point that has a bearing on the method of operation, although the wide application of flotation has to a great extent obvi-

ated the necessity for minimizing the proportion of slime, so that the object now is almost always to get a maximum of comminution. One of two typical problems may be presented. If a preliminary test is being made on which to base the design of a plant, the question is to determine the conditions of operation that will effect the most profitable result, that is, crush the maximum amount of ore to the desired fineness with a minimum expenditure for power and for the replacement of lining and balls. The required number of mills with appropriate motors or other driving units may then be provided. On the other hand, a fixed number of mills may be available in the plant and the problem may be to operate them in such manner as to grind the maximum amount of ore, regardless of any consideration of comparative cost. A few general statements that hold good under all circumstances may now be made. If less than 25% of the volume of the mill is filled with balls, the consumption of steel, including balls and liners, is excessive. There is a constant increase in the crushing capacity as the ball-load approaches 50% of the volume, but at approximately this point the maximum is reached and the capacity thereafter diminishes. Likewise the power consumed gradually increases with additional ball-load from no load to a point where the balls occupy between 60 and 65% of the volume of the mill, beyond which the power requirements decrease. A mill that is operating at maximum economic efficiency with 40% of its volume occupied by balls may conceivably have its capacity considerably increased by the addition of sufficient balls to bring this up to 50%, presuming that the motor is able to carry the added load. It may be, however, that the cost of additional power will more than offset the gain in the quantity of ore ground; in other words, the capacity is increased at the expense of ultimate efficiency. The entire subject of grinding in ball-mills is one of timely interest. Each ore, indeed each product, that is to be ground presents a problem in itself, but accurate and reliable data from actual operations are of great value in guiding the experiments of those who are still trying to improve their practice. There is mutual advantage in the exchange of definite information based on practical results and we shall be glad to give space for that purpose.

Hennen Jennings

With deep regret we record the death of one of the leaders of the mining profession, a man of rare sagacity and public spirit. We recite the details of his career on another page. Hennen Jennings belonged to a group of mining engineers to whom the American branch of the profession owes the larger part of its reputation abroad; they were the men with experience in large-scale gold-mining operations at a time, thirty years ago, when such experience was unavailable in other countries; they had received a good technical education and were prepared therefore to adapt their methods to new conditions. They succeeded in relieving results, in making money, and in winning great reputations. Of these men Hennen Jen-

nings was distinguished by a modest demeanor and a quiet sagacity that contrasted pleasantly with the opera bouffe posturings of sundry of his compeers. He was of the co-operative type, a willing helper, and a large-minded promoter of plans for the education and welfare of the mining communities amid which he lived. His going marks the near end of a great period in the development of the profession.

Thawing Frozen Ground With Cold Water

Frozen gravel can be thawed more readily with cold water than with steam. This statement will surprise most of our readers and will cause them to read with keen interest the article by Mr. Walter S. Weeks, Associate Professor of Mining in the University of California. Mr. Weeks gives a description, by Mr. John H. Miles, of the experiments made at Nome, Alaska, and then analyzes the results on a scientific basis, confirming the facts obtained in actual practice. We have added the sketch of a 'steam-point', the pointed tube that is driven into the gold-bearing sediment and that has served as a means of introducing superheated steam for the purpose of loosening the bonds of frost. A photograph, from a drift mine in the Klondike district, shows a battery of steam-points in place with the connecting lines of hose by which steam is conducted from a boiler. Until recently the hottest steam was deemed necessary for the purpose. The discovery of the fact that frozen gravel could be disintegrated by steam was a great event. It happened in 1898 near Dawson, when Mr. J. C. Berry noticed that steam escaping from the exhaust of an engine, used for hoisting gravel, had thawed a hole in the solid 'muck', that is, the frozen mud and moss that covers so much of the sub-Arctic surface. Mr. Berry took the exhaust-pipe, which was a rubber hose, and applied it to the frozen gravel near-by; he found that it would thaw the ground for the full length of the hose within a few minutes. Those who watched the experiment were greatly excited by the result, and several of them set to work immediately to devise a method for doing such work effectively. A rifle-barrel was chosen; then a small hole was bored into one side for the admission of the steam, and thus the 'steam-point' was invented. In its rudimentary form this device became a short length of iron pipe, pointed at one end and attached to a length of rubber hose through which the steam reached the gravel from the main pipe leading to the boiler. The pointed end of the five or six feet of iron pipe was inserted into the gravel and driven forward by gentle taps from a hammer as the ground was softened by the steam issuing from the orifice at the lower end. In course of time a solid head of steel was added to the end that was hammered and a protecting ring was welded to the forward end; the shank itself was made of pipe of the strongest kind and armored rubber tubing replaced the ordinary hose. The length of the 'point' was increased to as much as 16 feet and a hole in the steel head was bored for the insertion of a bar whereby the point could be turned so as to aid its penetration of the gravel. It proved useful, but clumsy.

partly because superheated steam is not easy to manage without excessive waste of thermal energy and partly because the scope of the 'point' is restricted to a narrow range of effectiveness. This is shown in the diagram, on which the dimensions of the thaw are given for the various mediums, ranging from superheated steam to cold water. It will be seen that a 'point' supplied with cold water thawed 511 cubic yards as against 109 cubic yards thawed by superheated steam. The results obtained with saturated steam and warm water were the poorest, the thaw being measured by 83 and 81 cubic yards respectively. Mr. Weeks proceeds to explain these results in terms of thermal units and shows that whereas 4% of the total heat in the superheated steam was actually effectual in the work of thawing, 57% of the total heat in the cold water was available for the purpose. Of course, the fundamental fact is that cold water, that is, water at 52 F., is warm relatively to ice and therefore competent for thawing. We feel sure that the record of these experiments, and of their scientific basis, will prove both interesting and useful to our friends in the North.

The Nomination of Hoover

On Friday, March 5, the engineers of San Francisco met at the Engineers Club and organized the Hoover Republican Club of San Francisco Engineers. The president of the club, Mr. Ely C. Hutchinson, was temporary chairman. He introduced Mr. Charles W. Merrill as chairman, and he in turn presented Mr. James M. Hyde as the principal speaker of the meeting. Mr. Hyde, an old friend of the Food Administrator, explained that the time had come to take action in order to have a Hoover delegation nominated at the primary election on May 4. He recognized that the demand for such a nomination was non-partisan, that the engineers would vote for Mr. Hoover on any ticket, but that as a matter of practical politics it was fairly evident that at this election the vote would be overwhelmingly Republican, and that therefore it was necessary, if it was desired to elect Mr. Hoover to the Presidency, to get him nominated by the Republican party, of the State and of the Nation. He made an eloquent and convincing speech. Mr. Warren Gregory explained the primary law and the method for obtaining signatures to the necessary petition. Usually, he said, an organization was first created in behalf of a candidate and then a ground-swell of public support was evoked; in the case of Mr. Hoover the process was reversed, the public demand came first and then the organization in his behalf. All those who spoke at the meeting laid stress on the fact that they had no authority to speak for him; he was keeping aloof from active participation in the political campaign on account of the important work he was doing as vice-chairman of the Industrial Conference at Washington, a work that he considered of so great importance that he would not jeopardize his usefulness in it for any consideration. Mr. C. H. Snyder was elected president and Mr. Arthur H. Halloran secretary of the Hoover Republican Club of San Francisco Engineers and they were authorized to co-operate with similar or-

ganizations in the State so as to promote united and co-ordinated effort in behalf of the election of the next President of the United States.

This may be regarded as a significant event. It may be said emphatically of the members of our profession that they will vote for Mr. Hoover on whatever ticket his name may appear; the ordinary party cleavage is disregarded in their profound realization of the fact that he is so pre-eminently the man best fitted for the responsibilities of the Presidency at a time when those responsibilities are especially difficult and weighty; they feel keenly that ordinary political partisanship must be set aside in the effort to elect a man whose record has proved him so peculiarly adapted to steering the Nation during the troublous period of economic reconstruction to which we have come in the wake of the War; many of them have a personal knowledge of, and a consequent esteem for, Mr. Hoover so great that both as engineers and citizens they intend to sever any traditional ties with their party in order to effect his election. Indeed, it is a rare opportunity that has come to the engineering profession; at the very time when the profession was awakening to its larger duties of citizenship and was about to take its part in the affairs of the community, the State, and the Nation; at the time when the stimulus of active participation in the national effort demanded by the War had made the profession proudly conscious of its ability to organize and direct big operations outside its customary field; at the time when Mr. Hoover himself had realized the ideal of engineering on a heroic scale; at that very time the steadily growing call across the whole of the United States for him to take the helm of the Republic has given engineers a chance to fulfill the dreams of civic usefulness, the ideals of public service, and the purpose of personal loyalty to the Chief, the president of the American Institute of Mining and Metallurgical Engineers and the supreme exponent of the responsibilities and privileges of the engineer in modern civilization.

The Premium on Gold

The dividends declared by the mines of the Rand for 1919 amounted to £6,287,205, as compared with £5,330,966 in 1918. We do not give equivalents in dollars, because the fluctuation of exchange would render it futile. The 'Financial Times', of London, says, with a chuckle, that "the actual dividends come within about £400,000 of the estimated working profits of £6,775,000". This is an acknowledgment of the fact that normally the official 'working profits' of the various mines and of the district as a whole are fictitious, in that they fail to allow for a number of essential expenditures. Usually they are wrong by 35 to 40%. For example, in 1915 the total 'working profit' was £11,931,062, whereas the dividends amounted only to £8,205,199. The approach to within 6½% of accuracy is due to the fortuitous help of the premium on gold during the last five months of 1919. This served to offset the statistical discrepancies caused by the customary failure to recognize the incidence of the excess-profits tax, the war levy, the Phthisis Act assess-

ments, and inidental expenses of various kinds. The premium on gold was about 20% during the last quarter of the year; it was enough to save some companies from collapse and to double the earnings of others. In the case of the Rand Mines Ltd., a large consolidation of holdings, the premium in November amounted to more than the monthly 'profit'. This pleasing phase of South African mining has moved our friend Mr. H. S. Denny to write an article on the subject for the 'Financial Times'. He shows that the 16 companies that were running at a loss during the last quarter of 1919 have earned a profit if gold had fetched 105 shillings. Since then it has been quoted at 127s. 4d. per ounce, a premium of over 50%. In 1912 when the cost was 18½s. per ton, as against 23½s. now, the Rand made £1,050,000 per month. Even with gold at 110 shillings, the profit of the mines of the Rand is increased 2½ times, making it £1,345,250 per month. With gold at 130 shillings, the profit would run to an additional £8,500,000 per annum, that is, 20s. per ounce on a production of 8,500,000 ounces of gold. Of course, the excess-profits tax cuts into this surplus severely, and, doubtless, both the Government of South Africa and the labor-unions will exact a share of the unexpected prosperity; all of it will not be left to the mining companies, although, for ourselves, we would like to see some of it go to the shareholders on whom the 'insiders' have been unloading their stock for years past. The general result is a remarkable revival of the Rand mining industry, an actual gain in dividends that has given the shares of the productive companies an entirely new status, and the introduction of a fresh gambling element of the most attractive character. Ordinarily the price of gold is regarded as fixed; in its stability it is considered superior to the vagaries of the base-metal market, or even of silver; yet within six months it has fluctuated by 50%. This is an entirely new phase of the gold-mining industry and renders it speculative to a degree and in a manner wholly undreamt by those engaged in it or by the onlooking economist.

As may be imagined, the mining companies operating in the Kolar district of India, which produced 461,000 ounces of gold last year, have been looking jealously at the good fortune of those in the Transvaal. During the early part of the War the Indian companies deposited their output of gold at the Bombay mint for sale to the Bank of England at the pre-war price. Later the Government of India allowed them to retain an amount of gold equal to their operating expenses. After May 1919 the Bank of England and the Government of India arranged for half of the Kolar gold to be sold in India for rupees, which were worth 1s. 7d. at that date. Since then the rupee has risen to 3s. in sterling exchange, so that the companies have been saved a heavy loss. Now the Indian companies have been given permission to sell all their gold in London, where a large premium is obtainable; but this is not so advantageous as it seems at first sight; their position is different from that of the South African companies because rupee exchange interposes. The South African operator sells gold and buys labor in shillings;

the Anglo-Indian sells in shillings, but buys in rupees. South Africa is a region so undeveloped industrially, apart from gold mining, that it cannot absorb its own output of the standard metal, whereas India is an ancient and thickly populated country, of greatly diversified industrial activities, that can absorb not only all the gold of domestic origin but much more, and can pay for it at a price considerably higher than the European market. South African currency is based on the pound sterling, whereas exchange with India at this time works adversely to Great Britain when exports are made from London to Bombay. It is delightful for the South African operator to take his gold to London and arrange for the proceeds to be credited in pounds by cable to his account at Johannesburg, whereas it is decidedly unpleasant for the Indian operator to bring his gold to London and to pay for his expenses at the mine by a remittance in rupees at a time when the rate of exchange is greatly against him.

These are some of the anomalies of exchange as they affect the miner. It is conceivable that a person with large investments in South African mines might find it advisable to live in England, so as to avoid the loss of exchange and the double income-tax. Other contingencies, humorous to those not affected by them, will suggest themselves. Meanwhile the American gold miner is waiting his turn, for it seems certain that here also gold must appreciate in due course, without special legislation for the purpose. Statements have been made, we understand, that the smelters in this country are paying \$20 for the gold in custom ores and obtaining \$30 for it themselves; also that the Japanese are buying large amounts of gold here for shipment to Nippon. Both these statements are untrue. The smelters receive \$20.67 for their gold from the Mint as heretofore and anybody can buy gold at that price from the Mint, by arrangement with the Federal Reserve bank or the U. S. Sub-Treasury, and use or ship it, at will, without license. At the present time this country is losing gold, to the Orient and South America, especially Argentina, and the suggestion has been made that an embargo be placed on export, as during the War, in order to check this drain, but if it goes for legitimate payments it would be unwise to stop it. Some of it goes to jewelers and manufacturers in Sweden, Switzerland, and other European countries. We have no law against the melting of coin; if gold went to the premium now paid in London, there would be great losses of coinage. In England it is illegal to deface or destroy coins; a number of arrests have been made recently on account of violations of the law. Obviously the gold standard is undergoing a severe trial, rendered peculiarly confusing by the disparity of industrial conditions in Europe and America. Some countries have lost all their gold and in others the last ounce is earmarked for the payment of indemnities. It has even been suggested that an international currency be established. These are matters of grave concern and more than parochial importance. It is to be hoped that an international conference will be called shortly and that the members of it will prove wiser than the gentlemen who lately assembled at Paris.

Thawing Frozen Gravel With Cold Water

By WALTER S. WEEKS

This article deals with experiments in thawing frozen gravel at Nome. These experiments led to the discovery that surface water could accomplish the thawing effectively without the addition of artificial heat.

The experiments were made by John H. Miles, now at Trinity Center, California. Mr. Miles has written a description of his work. He has asked me to prepare this for publication and to discuss it. The following is Mr. Miles's description of the experiments.

"In 1916 I was engaged by the Alaska Mines Corporation, of New York, to take charge of their dredging operations at Nome, Alaska. Their holdings consisted of a large acreage on the famous Third Beach, the greater part of which was permanently frozen, and of greater depth than had been thawed by the saturated-steam method used throughout the North. While ground from 10 to 25 ft. deep can be thawed by this method for about 24 cents per cubic yard, ground ranging from 40 to 80 ft. deep is almost impossible to thaw at a price that will leave enough margin of profit to pay the expense of dredging. I concluded therefore that it was necessary to discover a new method of thawing with this object in mind.

"I made the trip from 'the outside' to Nome over the long white trail, arriving there on April 16, 1917—32 days after leaving Chitina, which is the point where the dog-trail begins. I commenced my experiments in thawing immediately. Having had considerable experience with saturated-steam thawing, I was of the opinion that superheated steam at about 1000°F. would be the means of thawing at a reasonable cost. My belief was that concentrated heat introduced into the ground at brick would travel parallel with the bedrock and up, but I soon found that this was not the case, as the heat came to the surface immediately, and formed a pool of water so hot that one could not hold his hand in it. I could see that I was on the wrong track, and with fuel-oil at 8c. per gallon the cost of thawing would be prohibitive.

"I chose for my experiments ground that would offer the greatest resistance to thawing, the character of the formation having been ascertained by churn-drill holes. The formation consisted of tundra, muck, quicksand, clay, and fine gravel. This is a combination that is very hard to thaw with steam, owing to its ice content and the compact nature of the material. The clay content bakes around the steam-point, forming an insulation that prevents the heat from radiating from the steam-pipe, and forms collars in the thaw-holes sometimes not larger than four inches in diameter.

"After selecting a suitable locality, I assembled my equipment, which consisted of a 12-hp. boiler and a superheater, made of several coils of 2-in. pipe with brick

and sheet-iron housing. My first experiment was with superheated steam. I used three points of $\frac{3}{4}$ -in. double extra-heavy pipe drawn down to $\frac{1}{8}$ -in. opening at one end. Two of the points were lowered into 6-in. churn-drill holes, the third was put down in the following manner: A 1-in. double extra-heavy pipe drawn down to $\frac{3}{4}$ -in. opening at one end was used, a clamp was placed around the pipe, and a weight having a hole in the centre was slipped over the pipe and attached to the walking-beam of a Keystone drill, which raised and dropped the weight, striking the clamp, and forcing the pipe. The pipe was rotated slightly at each blow by use of a Stillson wrench. Warm water at 20-ft. head was forced through the pipe, thawing and softening the ground at the point. In this manner the pipe was driven down 42 ft. in four hours and ten minutes.

"In the following season I developed a combination rotary-percussion drill, consisting of a 2-in. pipe with a serrated steel shoe, using cold water at 80 lb. pressure flowing through a pipe. The pipe made 20 revolutions per minute, and an 80-lb. weight, which dropped 60 times per minute, helped to force it down. With this machine I was able to sink the 2-in. pipe 40 ft. in one hour and twenty minutes. The pipe used in this machine is left in the ground and used as a thaw-pipe, the high-pressure water being replaced with low-pressure water at whatever head is available. This machine proved satisfactory for the soft formation. In like formations of shallow depth it is not necessary to force the pipe down by mechanical means; the pipe will sink of its own weight if rotated slightly by hand. I do not know what the results would be in a heavier formation containing large boulders.

"The results of the superheated-steam thawing were most unsatisfactory. After steaming for a few hours, the ground around the pipe began to sink, forming a lake of hot water, and the longer we thawed the hotter the water became. It became evident that with so much heat coming to the surface, very little thawing was taking place on bedrock. The nature of the ground was such that when thawed it was possible to probe with an iron bar to a depth of about 25 ft. By using this bar, I ascertained that the thawing in these holes was being done in the form of an inverted cone, as was subsequently proved when these thaws were dug out.

"Next I put in three saturated-steam thaws, using ordinary steam-points, but instead of driving with hammers, as is the common practice on shallower ground, I dropped the pipes into holes previously drilled by a Keystone machine. These tests showed very similar to superheated-steam tests, with the exception of thawing an in-

verted cone slightly smaller on top and extending to a greater depth.

Then I tried hot water, using three holes, having heard of experiments conducted at Dawson with good results. A 1-in. double extra-heavy pipe with $\frac{1}{2}$ -in. outlet was used. Hot water drawn from the blow-off cock of a boiler was circulated through the pipe at an average temperature of 105° . By probing with an iron bar, I was able to determine that this method was far more efficient than the previous steam-tests from the fact of the walls of the hole being nearly parallel. But, as in the steam-tests, we were losing heat-units because the water failed to deliver its heat in the ground, but carried it to the surface, where it was wasted. This led me to think that thawing was a slow process, and that it was not a concentrated heat that was necessary, but a uniform circulation of water with just a few heat-units to give up. It then occurred to me to try surface water, the temperature at that time being 52° , and the temperature of the ground 28°F . Not having ditch-pressure available, I used a steam-pump with a 2-in. suction and $\frac{1}{2}$ -in. discharge. This pump delivered 20 gallons per minute at an average pressure equal to a 40-ft. head. The pump was connected to a 2-in. pipe, which was dropped into a 6-in. Keystone drill-hole.

"No results were apparent for 24 hours, when the 'muck' began to slough from the sides of the hole and retarded the circulation of water in the hole. From that time on one could see the progress of thawing. In 36 hours an 8-ft. area was thawed, and upon probing with an iron rod we found that the walls of the thaw were vertical, not the shape of an inverted cone as in the steam thaws. This was very gratifying. We watched the progress of thawing with increased interest. At the end of the eighth day, we decided to stop thawing on this hole and start another for a check, owing to the lateness of the season. The water entering the ground had a temperature of 52° ; at the end of 24 hours the outgoing water was at 50° ; at the end of 48 hours, 48° ; at the end of 72 hours, 45° ; at the end of 86 hours, 40° ; at the end of 192 hours, 36° . To obtain maximum efficiency the amount of water entering the thaw-pipe should be governed by the temperature of the outgoing water. Just enough water should be used to keep the temperature of the outgoing water a little above freezing.

"In watching a cold-water thaw in operation, one sees the water boiling up around the outer edge of the hole, not in the centre. My theory of the operation is that the ground in thawing forms a porous streak between the frozen and thawed area, and the water finds less resistance in this channel than in the thawed area. Consequently, it takes this course and draws the frost with it, forming an ever-increasing area.

"The time consumed in these experiments, which included three superheated-steam thaws, three saturated-steam thaws, two hot-water, and two cold-water thaws, was from the 20th of April to the 25th of October, when the weather became too cold for further experiments. I had a good idea of the amount thawed and the shape of

each thaw from being able to use the long iron rod to prod through the loose thawed material, but I wanted an exact cross-section of each thaw. On December 1, when the surface water had frozen so that it was possible to sink shafts without the necessity of pumping, I let contracts to parties to sink shafts over the thawed test-holes in order to ascertain the exact amount of material thawed and the shape of each hole. This work was finished on December 20, 1917.

"The results of these experiments will be found in the accompanying chart. See Fig. 1. In my opinion the cold-water thaw was most advantageous because, first, it thaws a larger area on bedrock, and into bedrock itself for a considerable distance, thereby making it possible

for dredges to clean the bedrock without encountering the frozen pinnacles and frozen spots, which are invariably left by the present method of steam-thawing. I know of one dredge in the Nome district that lost its entire season's work by encountering these frozen pinnacles on bedrock when trying to dredge ground that had been supposedly thoroughly thawed by steam.

"Secondly, the heat units needed to thaw are supplied by nature at no expense to the operator, consequently ground in the outlying districts, where it has been impossible to procure fuel for steam-thawing, can now be thawed at no greater expense than ground near a fuel supply, thus opening for the prospector and operator a large area of the frozen North.

"Thirdly, the actual cost of thawing in ground such as I chose for my experiments, or ground much deeper, will be less than one cent per cubic yard, while the deep ground will necessitate some mechanical means, such as I have briefly described, to insert thaw-pipes. The shallower ground will not need any mechanical means to insert pipe, but will necessitate moving pipes more frequently, which will offset the cost of the machine, and will, I think, cost about the same, or possibly a little more per yard.

"In the spring of 1918 I had occasion to thaw a block of ground 130 ft. long by 80 ft. wide, by 11 ft. deep, composed of pure beach sand. I was interested to see what would be the difference in time between steam and cold-water thaws in actual operation, so I rigged up a battery of 12 points, using steam from a 20-hp. boiler. The men employed were experienced in steam-thawing, working two 12-hour shifts. At the end of the third day we had an area 20 ft. square partly thawed. I mean the area

A STEAM-POINT

was thawed on the surface, but by prodding down with a bar one could feel lumps of frozen ground. We stopped steam-thawing, put in a 4-in. centrifugal pump, from which we brought 12 one-inch openings. To each opening we attached a 12-ft. length of 1-in. garden hose, and

pipe would be about 6 inches in diameter. The pipe was left in the hole 30 minutes longer. The hole would then be about 36 inches in diameter. The pipe would then be drawn and started in a new hole. It was found best to move the pipe after about 45 minutes, as the water seem-

Super-Heated Steam Thaw
 150 hours steaming.
 1755 gal. oil used.
 160° C. steam at boiler.
 310° C. steam at points.
 60° C. water at surface.
 109 cu. yd. thawed.

Saturated-Steam Thaw
 98 hours steaming.
 882 gal. oil used.
 160° C. steam at boiler.
 120° C. steam at points.
 40° C. water at surface.
 83 cu. yd. thawed.

Warm-Water Thaw
 67 hours thawing.
 405 gal. oil used.
 44 ft. depth of ground.
 105° F. water at points.
 70° F. water at surface.
 81 cu. yd. thawed.

Cold-Water Thaw
 192 hours thawing.
 20 gal. water per min.
 40 ft. pressure.
 52° F. water entering.
 511 cu. yd. thawed.
 1.9c. cost per yard
 \$5.75 cost of drilling hole to install
 thaw pipe.
 \$4.20 cost of connecting and dis-
 connecting pipe.
 No charges made for use of water.

Note: 8c. per gal. cost of oil. 70c. per hour cost of labor when thawing. \$11.50 per shift for labor when inserting points.

STEAM-POINTS IN PLACE IN A LAYER OF GOLD-BEARING SEDIMENT, COVERED BY FROZEN GRAVEL, WHEN THAWING IN THE USUAL WAY

on the end of each hose was attached a piece of common 1-in. pipe 12 ft. long. There was hardly any pressure at the end of the pipe, probably one pound, not more. The pipes were held up by hand until they had sunk about one foot into the sand, then they were left alone to sink into the sand as they thawed. In 12 minutes the pipe would sink through 11 ft. of sand. The hole around the

ed to start circulating under the 11-ft. cap of frozen sand and the thawing action on sides of holes was retarded. With these 12 one-inch pipes two men thawed the remainder of the area, and also re-thawed the ground partly thawed by steam in four days and nights. The whole area was thoroughly thawed."

In brief, thaws were 'put in' with superheated steam,

saturated steam, hot water, and cold water. In each case the thawing medium was introduced at the bottom of a churn-drill hole. When the surface water was frozen, shafts were sunk on the drill-holes and the volume of the thaw determined. The chart (Fig. 1) shows the cross-section of a thaw of each type.

Let us attack the subject from the point of view of the heat-units involved.

The gravel, at the place where the experiments were made, weighed, as nearly as I have been able to determine, 3000 lb. per cubic yard, and each cubic yard contained about 300 lb. of ice. Nearly all the heat used in thawing frozen ground is consumed in melting such ice as may be there, so, for such an approximate calculation as this, we may neglect the small amount of heat used in raising the temperature of the solid material. In the steam and hot-water thaws our only information about the available heat is the amount of oil used. I think it will be reasonable to assume a 50% boiler efficiency and so debit the thawing medium with one-half the heat-units in the oil used. Since we are guessing at the boiler efficiency, it would be too great a refinement to consider the heat in the feed-water.

Let us consider the experiments in the order in which they appear on the chart.

No. 1—Superheated Steam

Hours	156
Gallons of oil	1755
Cubic yards thawed	109

To determine what proportion of the heat supplied in the steam was used in thawing, I shall use hourly quantities in order that the figures may be less unwieldy.

Gallons of oil per hour	11.25
Cubic yards thawed per hour	0.7
B.T.U. per gallon of oil	140,000

If we assume a boiler efficiency of 50%, we shall have available 70,000 B.T.U. for every gallon of oil used.

B.T.U. necessary to melt one pound of ice	144
B.T.U. supplied per hour	$11.25 \times 70,000 = 787,500$
B.T.U. necessary to melt ice per hour	$0.7 \times 300 \times 144 = 30,240$
Efficiency of absorption	$\frac{30,240}{787,500} \times 100\% = 3.8\%$

No. 2—Saturated Steam

Hours	98
Gallons of oil	882
Cubic yards thawed	83
Gallons oil per hour	9
Cubic yards thawed per hour	0.85
B.T.U. supplied per hour	$9 \times 70,000 = 630,000$
B.T.U. necessary to melt ice	$0.85 \times 300 \times 144 = 36,720$
Efficiency of absorption	$\frac{36,720}{630,000} \times 100\% = 5.8\%$

No. 3—Hot Water

Hours	67
Gallons of oil	405
Cubic yards thawed	81
Gallons of oil per hour	6.04
Cubic yards thawed per hour	1.21
B.T.U. supplied per hour	$6.04 \times 70,000 = 422,800$
B.T.U. necessary to melt ice	$1.21 \times 300 \times 144 = 52,272$
Efficiency of absorption	$\frac{52,272}{422,800} \times 100\% = 12.3\%$

No. 4—Cold Water

Hours	192
Water per minute, gallons	20
Cubic yards thawed	511

In this case we are able to determine directly the available heat-units.

Water per hour, gallons	1,200
Cubic yards thawed per hour	2.66
Temperature of water introduced	52 F
Heat-units per pound of water theoretically available	$52 - 32 = 20$

Heat-units given up per gallon	$20 \times 8.35 = 167$
Total heat available	$1200 \times 167 = 200,400 \text{ B.T.U.}$
Heat necessary to melt the ice	$2.66 \times 300 \times 144 = 114,912 \text{ B.T.U.}$
Efficiency of absorption	$\frac{114,912}{200,400} \times 100\% = 57.4\%$

To summarize: of the total heat applied in each case the following proportion was actually used in doing the useful work of thawing:

Superheated steam	% 4	Hot water	% 12
Saturated steam	6	Cold water	57

A study of the steam thaw shows that the clay was penetrated only to a slight extent. The description would indicate that most of the heat in the steam was expended in keeping hot a comparatively quiet pool of water. There could have been very little circulation of the hot water because a 12-hp. boiler will evaporate only about one gallon of water per minute.

The hot-water thaw shows uniform thawing, but low efficiency. The efficiency of the heat absorption increases as the area of frozen ground in contact with the thawing medium increases. This is clearly shown in the temperatures of the outgoing water in the cold-water thaw. If the hot-water thaw had been continued as long as the cold-water then the efficiency doubtless would have been much greater.

The cold water apparently accomplishes all that is desired and at slight expense. Clay is no impediment. A vigorous circulation must be maintained so that the cooled water is quickly removed and replaced by more, which has a few heat-units to give up.

In the 'Engineering and Mining Journal' of March 22, 1919, there is a short description of the results obtained on Candle creek by the cold-water method. I understand that other tests have been made in Alaska during the past season. I am sure that any discussion or information on the subject will be welcome to the engineering profession and to mine-operators in the North.

A PROCESS of extracting aluminum from labradorite has recently been developed in Norway. The process involves the solution of labradorite in dilute nitric acid made locally, leaving the impurities as a residue; evaporation and heating to a point at which the aluminum nitrate alone is decomposed; and the dissolving of the calcium and sodium nitrates in water, leaving pure aluminum oxide. Labradorite, as ordinarily found in this country, is not sufficiently soluble in nitric acid to make this process seem feasible on a commercial basis; but it is possible that the Norwegian material is not a true labradorite and is much more soluble. Pure labradorite contains about 30% alumina or 16% metallic aluminum. —U. S. Bureau of Mines.

For the first eleven months of 1919 the value of silver exported from the United States to India amounted to \$109,180,718 while China's share (including Hongkong) was \$60,125,178. For the first seven months of 1919 the proportion was \$108,273,177 to India and \$17,458,606 to China and Hongkong. This gives an idea of how the Chinese demand has grown.

The Distillation of Shale-Oil

By JAMES A. BISHOP

The first essential in operating chemically upon any substance is to familiarize ourselves with its nature and compounds. Until this work is accomplished no operator can define concisely the problem before him, and not knowing his problem, he can develop only a vague idea of the chemical and mechanical requirements of the machine through which he should operate. The subject of shale-oil distillation naturally directs our attention first to the origin of the substance commonly known as kerogen, which occurs in some shale formations, and from which oils that are similar to crude petroleum may be secured. As many theories for the deposition of kerogen are being advanced, this phase of our subject may profitably be deferred until an accumulation of data will direct our efforts more accurately. A subject of greater importance is the nature and qualities of those compounds which may be educted from kerogen, or, stating it more scientifically, those commercial compounds into which worthless kerogen may be resolved.

CONSTRUCTIVE V. DESTRUCTIVE DISTILLATION

Seemingly in defiance of the chemical engineer, in the formation of kerogen, Nature has utilized that series of hydrocarbons deriving the name paraffin, meaning 'without affinity', from this inert quality. Those chemical reagents which do act upon the paraffin compounds are too expensive to justify their use commercially in any form of digesting process. We are thus driven to the use of heat, and since the compounds derived from kerogen are all combustible and some of them explosive, the charge must be treated in an air-tight oven and the heat applied externally. This form of discharging the volatile from the solid or non-volatile is called distillation. The process falls naturally under two classes: (1) Some substances are composed of simpler compounds which vaporize at different temperatures, and hence can be separated without chemical change to the various units. (2) The constituent compounds of other substances seem to be so interrelated chemically that the difficulty of their isolation causes the elements to resolve themselves into new compounds, usually of simpler molecular formulae. This is especially true when acted upon by excessively high temperatures. The name 'destructive distillation' is applied to the formation of these new compounds. The term is unfortunately chosen and is often misleading, especially to the layman in the art of distilling, who, since he is engaged in destructive distillation, believes that the most complete destruction of his original compound will ensure better results in the end. We know that the organic matter composing kerogen contains a given amount of carbon and hydrogen. We also know that by proper manipulation we can cause combinations of those two

elements in such proportion as will produce compounds of commercial value. The real essence of our work is 'constructive' rather than 'destructive'. Even though our results are secured through distillation, we maintain that we are manufacturing commercial products from Nature's crude materials, and that our process is based upon constructive distillation.

CHEMICAL AND PHYSICAL PROPERTIES

Through many analyses of the organic matter deposited in shale we know that it is composed principally of that form of hydrocarbons known as the saturated, or paraffin, series. Normal paraffin hydrocarbons are composed of but two elements, carbon and hydrogen, combined under one constant ratio, such that the hydrogen atoms equal twice the carbon atoms plus two. Thus, if 'n' represents the carbon atoms in the compound, $2n + 2$ represents the hydrogen atoms, hence the symbol C_nH_{2n+2} may represent each and every compound of the series, ranging from CH_4 , methane gas, to $C_{66}H_{134}$, hexacontane.

For the sake of comparison let us examine the first half dozen symbols showing the straight-line linkage of the normal paraffin series of the hydrocarbon compounds.

The first and simplest of the carbon compounds is methane gas, a product of the mild force of decay, where the carbon atoms are easily disengaged and we find an abundance of hydrogen to satisfy, or saturate, their four valence bonds. The gradual diminution of the hydrogen supply forces Nature to economize in its use, while increasing the heat for the separation of the carbon atoms for use in the succeeding compounds. While hydrogen decreases from 80 to 70%, carbon increases from 20 to 30% in the first six members of the series. The physical conditions of the series range from the light methane gas to light liquids, to heavier liquids, to fuel and lubricating oils, and finally to solids as determined by the predominating element hydrogen or carbon.

The hydrocarbons form a large group of organic substances, and may be divided into two main classes, saturated and unsaturated. The saturated are so called because the carbon atoms composing the molecule are connected by single bonds. So long as only one bond exists between the carbon atoms, no other atoms, as hydrogen, chlorine, etc., can be easily added to the molecule. It is, therefore, said to be saturated, and having slight affinity for other atoms, the terms saturated and paraffins are used interchangeably.

When carbon atoms within the molecule are joined by two or more bonds, one of those bonds may be easily broken and the carbon bond may be used to engage an atom of a different element. Such hydrocarbons are said to be unsaturated and belong to a different series. The double linkage of the carbon to carbon atoms does not produce a firmer union, as we might suppose, but the breaking of the chain at the double linkage seems to indicate a divided attraction of carbon to carbon at that point.

Although we maintain that a skilful operator may educt and refine his oils into either series *ad libitum*, the paraffins at present are demanded by the public. We will therefore discuss those problems which constitute a part of the paraffin-distillation process.

The lack of uniformity in the hydrocarbon contents of shale indicates an incipient decomposition after the deposits were made. The residue is clearly an asphaltic hydrocarbon in which the element, carbon, predominates. The first appeal, therefore, to the operator is the conservation of his stock in hand of hydrogen. The waste of that element in the first-grade distillates means a deficiency of hydrogen in the third grade and the solidifying of carbon into worthless coke at the expense of the vaselines, paraffins, and tars. The charge of shale will be brought to a distilling temperature very gradually if that will-o'-the-wisp, hydrogen, is to be retained for the liberation of enough carbon to convert it into light oils, rather than fixed gases. Owing to the small content of carbon in those oils distilling under 150°C. their specific gravity is light, the degree of viscosity is low, and their vapors are fairly elastic. For these reasons the distillates of the first grade will transport themselves from the heated regions of the distil to those of safety, if opportunity to do so is given them. The instant removal of the second and third-grade distillates is of gravest importance and merits our most careful consideration.

THREE GRADES OF DISTILLATES

There seem to be no valid reasons which justify the construction of the distil and its condenser for fractioning the distillates into more than three grades, unless the condenser has a cooling capacity which will pass the so-called fixed gases through a freezing temperature. In that case a fourth grade might be profitably added for the liquefaction of rhigolene. The three grades are: (1) those whose boiling-points range from zero to 150°C. = 302°F.; (2) those boiling between 150°C. and 300°C. = 572°F.; (3) those boiling above 300°C.

The still must be regarded and operated as the most important factor of a shale-oil eduction plant. Any values escaping the still go with the spent shale into the discard, and all oils improperly treated are either lost or so reduced in value that their reclamation in the refinery is impossible. However, the still and its condenser should be subservient to the refinery. The oils should be educted and liquefied in such a manner as will assist the refinery in satisfying the demands of a critical public. The three sections of the still producing the three grades above named should be well defined, at least in the mind of the operator, and so constructed as will make changes of manipulation possible. The manager of the still and condenser should reasonably understand the fractioning which his three grades of still products will undergo in the refinery.

A liquid exposed to the air evaporates, or passes into a state of vapor, but under similar conditions different liquids evaporate at different rates. If heat be applied the rate of evaporation increases. As the molecules of the vapor accumulate over the surface of the liquid they exert a pressure against the atmosphere. This pressure is called 'vapor pressure'. When vapor pressure exceeds atmospheric pressure bubbles pass up through the liquid, which is then said to boil. At the boiling-point the liquid passes rapidly into a vaporous condition, and the ability of a liquid to vaporize, that is, its vapor pressure, determines its boiling-point. It is evident that the operator must know, from the temperature he applies, exactly what part of his charge he is vaporizing.

FRACTIONING THE THREE GRADES

The members composing the paraffin series run into the hundreds, and about sixty, ranging from methane gas, CH_4 , to hexacontane, $\text{C}_{60}\text{H}_{122}$, with many of their isomerides, have been separated. Shale distillates, however, when properly treated are all included in the first 35 members of the paraffins. The first four members, although usually considered gaseous, may be liquefied by cold and pressure. Thus methane, the lightest and simplest of the series liquefies at -164°C . and solidifies at 186°C . But such extreme temperatures prohibit the liquefaction of the first members for commercial purposes. They are, therefore, considered fixed gases. The next eleven members, including $\text{C}_{15}\text{H}_{32}$, vaseline, are liquids or semi-liquids, while all beyond are solids, with melting and boiling-points increasing as the molecular weights increase. The addition of each CH_2 raises the boiling-point of the resultant members.

Owing to the fact that kerosen was first deposited in bogs or lakes, the chemical action of decay no doubt liberated the light inflammable methane gas, CH_4 . We therefore find that kerosen supplies only limited quantities of that gas. The fourth member, butane, though strongly of a gaseous nature, may be condensed to a liquid at zero°C. This liquid is called cymogen, and as it boils at one degree above zero its preservation in a liquid state is somewhat difficult. It is sometimes used in refrigeration.

The first liquid to condense through ordinary means is the condensate of pentane, C_5H_{12} , and is called rhigolene. Since it boils at $18^\circ C. = 64.4^\circ F.$, it will escape the condenser, and remain with the so-called fixed gases, unless subjected to a freezing temperature. Rhigolene is used as a local anesthetic by the medical profession, and in some foreign countries for the production of a flame of standard luminosity.

As the temperature rises to $70^\circ C.$ the second liquid distillate vaporizes; after liquefaction this is known as benzine (not coal-tar benzol). From this fraction three oils may be derived: (1) gasoline, consisting principally of pentane and hexane; (2) motor-oil of commerce, consisting largely of heptane, C_7H_{16} ; (3) the heavy portions distilled below $150^\circ C.$ in their liquid state, which are called lignoil and are often used as polishing-oils. They consist principally of octane, C_8H_{18} , and nonane, C_9H_{20} .

The paraffin members having boiling-points between $150^\circ C.$ and $300^\circ C.$ are eight in number and terminate with heptadecane, $C_{17}H_{36}$. The last member supplies some of the low-melting vaselines. The oils derived from the second-grade distillates are known as 'kerosene', or illuminating oils, in America, and as paraffin, or lamp-oil, in Great Britain. The heavy portions of this fraction supply lubricating oils.

After the removal of all distillates which are educted from shale by a temperature of $300^\circ C.$, there remains a residue which is sometimes used as fuel oil, but from which such valuable products as lubricating oil, paraffin, and tars may be fractioned. Owing to the high boiling-point of the third-grade distillates their fractioning demands scientific knowledge and skill. Thus when fractioned under vacuo there remains a substance, vaseline, of doubtful composition, ranging from hexadecane, $C_{16}H_{34}$ to eicosane, $C_{20}H_{42}$, together with some of the unsaturated hydrocarbons.

Even in this brief review of shale-oil distillation we cannot dismiss the subject without mention of two more important compounds. The heavy hydrocarbons ranging from $C_{24}H_{50}$, tetracosane, to $C_{35}H_{72}$, pentatriacontane, form the highly important commercial paraffin wax and tar. Because of the 10% to 30% of suspended carbon in tars they usually assume very dark colors. They contain small proportions of acid, and basic products, together with higher percentages of neutral compounds, which are modified by the temperatures and the style of the distil employed. A carefully managed distil will avoid the production of the benzenes, unless their market price should invite such production. The neutrals may be fractioned into many different products, but four especially have wide applications; namely, benzol, phenol, toluene, and naphthalene.

A few persons of limited experience are demanding a shale-oil retort so constructed that the distillates from shale be fractioned in the retort. The foregoing brief outline should convince the advocates of the combined operations that the distil is not a refinery, and cannot, except in a restricted way, perform the work of both. The extraction of the oil from shale is first in importance,

and entangling processes in connection with that of distillation should be avoided. The delivery of the different fractions requires a sectional distil, each section of which will demand special supervision. The fixed gases naturally constitute one of the fractions and instant isolation from the oils prevents any possible chemical combination therewith. Distil fractioning means the production of an excessive volume of gas. Fractioning may be accomplished in two ways: (1) by the injection of given temperatures for each product; (2) by the extraction of heat from its vapors, each product liquefies as the temperature falls below its boiling-point. The second operation may be performed in the condenser as the mixed vapors are discharged from the distil. But neither the distil nor the condenser can complete the fractioning in a manner that will satisfy the demands of the oil industry. All the fractions from the distil or its condenser must pass through a refinery equipped for the exacting work required. Why, then, attempt the impossible through the eduction plant, when unsatisfactory results are the only possible compensation for a reduced tonnage?

PARAFFINS, OLEFINS, AND BENZENES

The association of kerosen with shale strongly indicates sedimentary deposition in bogs or lakes. It seems, therefore, highly probable that kerosen has escaped the destructive influence of heat, except the mild temperature of organic decay, which was insufficient for the reduction of paraffins into olefins or benzenes. These conditions point strongly to the existence of paraffins only in shale deposits, and that the presence of either olefins or benzenes in the distillates suggest improper methods of distillation. This conclusion is supported by the fact that a careful review of the annual output of large European distils reveals no benzenes as direct distillates from shale.

THE CRACKING OF HEAVY OILS

Cracking processes are exclusively refining methods and have no place in a shale-oil distil. Any shale distil so constructed that the cracking of oil distillates cannot be avoided is fit only for the discard. Cracking is a decomposing method. It might be called a reduction descending process. The paraffin hydrocarbons, though inert to many reagents, are extremely sensitive to the influence of high temperatures, and high temperature distillation greatly increases the volatile constituents of the distillate. This principle was discovered in 1861 through the accidental over-heating of an oil-still. It was found that the contents of the still had been changed to lower homologues of the paraffin series, and in part to the olefine and benzene series. The process takes its name from the popping or cracking sound often heard in connection with the boiling of a dense heavy fluid. The name, cracking, gives no suggestion of the principles involved in the process. The cracking of the paraffin hydrocarbon $C_{15}H_{32}$ might give a lower paraffin $C_{10}H_{22}$ and the olefine C_5H_{10} or it might give the paraffin C_7H_{16} and olefine C_8H_{16} . Let it be observed that the olefine contains only twice as

many hydrogen atoms as carbon while the paraffin contains twice as many hydrogen atoms + 2.

The sensitive nature of the paraffins when subjected to high temperatures is undoubtedly due to the constantly diminishing supply of hydrogen, and a greater supply of carbon atoms as the temperature rises. Let us assume that the portion remaining in the paraffin series had the advantage of position, less heat, or in contact with a greater number of hydrogen atoms. It simply discards a portion of its carbon and gathers in a higher percentage of hydrogen. The outcast carbon cannot secure the proper number of hydrogen atoms to build up a higher paraffin compound, much less one of the lower members of the series, where a higher percentage of hydrogen is required. Nature is now burdened with a misfit number of carbon and hydrogen atoms, and there seems nothing to do but to bolt the paraffin series and place her refugees into the olefines, where one carbon is compelled to exist with only two hydrogen atoms. Or failing in this she is forced to knock at the door of the benzenes for admission, where one carbon must be content with one hydrogen. There remains only one more alternative if the proportions of carbon and hydrogen are not numerically correct, namely, a complete divorcement of the two stray elements, by which hydrogen is forced to travel alone as a gas, and carbon uniting with carbon solidifies into coke.

When compounds contain an excess of carbon, under high temperatures the diminishing supply of hydrogen fails to satisfy or saturate the released carbon atoms. The straight-line linkage of the paraffins no longer serves as the chemical yard-stick for determining the nature and composition of the hydrocarbons. Although carbon has a strong affinity for other elements it will, under high temperatures and a limited supply of other elements, unite with itself. Three bonds link carbon to carbon, leaving only one bond to be satisfied by some other element, as hydrogen, thus using equal numbers of carbon and hydrogen atoms in the new compound. The hydrogen content is reduced from 14 as in the paraffin, hexane, to six atoms in benzene, the model compound of the benzene or chain-linked series.

VISCOSITY RETARDS DISTILLATION

When heat is applied to the organic solids incorporated in shale, it at once becomes the opponent of two dormant forces, one chemical, the other physical. These forces are forms of attraction which act at insensible distances. The chemical force is called affinity, and acting between the atoms of different elements parcels them into groups, or molecules, according to the linkage of that series which the degree of heat renders permissible. The physical force, known as cohesion, acts between the molecules and determines the character of the substance as solid, liquid, or gaseous. If only sufficient heat is applied to convert the solids into liquids, the chemical force will, no doubt, arrange the atoms after the plan ordained by the paraffin series of hydrocarbons. But liquids are not susceptible of motion as vapors are and the process must be carried one step farther. The next step is a delicate one. We

wish now so to weaken the cohesion that the liquid becomes a vapor without disturbing the atomic arrangement within the paraffin molecule. In other words, we want the paraffin molecule in the vapor state to remain identical with the paraffin molecule in the liquid state with only a change in its cohesion. But cohesion is a force to be reckoned with since it varies from almost imperceptible attractions to enormous tensile strength. We are all familiar with the sledge-hammer blows required to drive a cold chisel through a bolt or bar of cold iron. The blacksmith weakens the cohesion by heating his iron to 1800° F. at which temperature he cuts his bar with ease, and the foundryman by injecting 2800° F. of heat drives the iron molecules so far apart that cohesion is neutralized and the iron lies as a noncohesive liquid in his ladle. In like manner, though in milder degree, we drive the paraffin molecules asunder by the injection of heat, but at the risk of destroying the chemism between the atoms and changing the structure of the molecule. In endeavoring to retain the internal structure of the molecules we fail to neutralize completely the cohesion between them. There remains, therefore, in small degree, a viscosity between the oil-vapor molecules which causes them to hang together and form an obstructing layer over the shale charge. Distilling under a partial vacuum has been suggested, but a vacuum has neither a pull nor a suction upon an inert vapor. Although we speak of the suction pump, the plunger of a pump has no lifting power until it gets under the substance to be pumped. As the plunger rises the expansion of air within the pump forces it to follow the plunger and keep the space filled. As the pressure within the pump decreases water rises, not from a pull or suction, but from the downward atmospheric pressure on the outside water surface. The water ascends in the pump for exactly the same reason that the light end of a scale beam rises. Whether the distillation is performed under vacuum or not, it is evident that the transportation of the oil-vapors is dependent upon their own expansion qualities, or that of some auxiliary vapor.

Crystallography is so exact a science that substances may often be recognized by the form and structure of their crystals. Had we the power of viewing the molecules which compose the crystals, we would doubtless find them just as methodically constructed as to size, form, and weight. Any aggregation of the molecules composing the inert vapor layer over the shale charge may be well represented by a box filled with marbles of exactly uniform size. The spaces between the marbles will show as great uniformity as the marbles themselves, but no space is of proper shape and size to admit one of the marbles. We may assume that vapor molecules liberated from the shale charge will bombard the under side of the vapor layer for a passage. They cannot enter the intermolecular spaces, because they are not of proper size or shape. They must either lift the vapor layer or violently disrupt the temporary arrangement of its molecules, either of which will require an excessive amount of heat, and result in cracking the vapors.

THE USE OF STEAM IN DISTILLATION

European operators discharge large volumes of steam into the shale charge on the theory that it assists in dissolving, distilling, and cushioning the paraffins. The term 'cushioning' seems to carry a doubtful meaning, and we think may be profitably exchanged for 'transporting'. We know that the expanding or carrying powers of vapors from different liquids is by no means uniform. A cubic inch of gasoline vaporized expands into 320 cu. in. of vapor of the same pressure as the gasoline. But a cubic inch of water vaporized expands into 1728 cu. in. of steam of equal pressure to the water. Thus the expansion of water vapor is more than five times that of gasoline vapor. Water evaporated in a vacuum quickly occupies the entire space of the vacuum. Although gasoline vapor will in time fill the entire vacuum cavity, its low expansion value compels a sluggish action. The vapors secured from liquids whose boiling-point is above 300°C. are even slower in their expansion than those of gasoline, and lie heavily upon the surface of the charge. To illustrate the difference in their volatility, place a drop of water and a drop of oil side by side on a piece of glass. The water quickly evaporates and disappears. The oil remains unchanged, perhaps for days, due to its viscosity, a quality not possessed by the water. As we might expect, this hanging clinging quality of oil raises its boiling-point far beyond that of water, and renders the separation of its molecules into a vapor state somewhat difficult. Since 100° of heat overcomes atmospheric pressure in boiling water, having very slight cohesion, we may safely conclude that the additional 200° required for boiling oil is used in neutralizing the cohesion of its molecules. Hence, any process that will assist in breaking the cohesion of oil-molecules lowers the boiling-point to just that extent. Two oils are said to be miscible when their molecular surfaces adhere to each other. If two such oils are mixed in a still charge a new opposition force to the boiling-point is added. Enough heat must be applied to overcome atmospheric pressure, the cohesion of like molecules and the adhesion of unlike molecules. The boiling-point will very naturally be raised. On the other hand, if two nonmiscible liquids, as water and oil, are distilled together, each will vaporize just as if the other were not present. There is no adhesion between the molecules of oil and water. The vapor molecules of one occupy the intermolecular spaces of the other. Each contributes to the vapor pressure upon their surface, and when their combined vapor pressures equal the atmospheric pressure, boiling or rapid evaporation takes place. The highly expansive water molecules push the oil molecules farther apart. This increase of space between the oil molecules weakens their cohesion and rarefies the vapor mass. Now rarefaction means less vapor pressure upon the shale surface. It is evident that any vapor pressure exerted by the water vapor (steam) relieves the oil vapors to that extent in counterbalancing atmospheric pressure, and lowers the boiling-point of the oil. It is the equivalent of distilling the oil in a partial vacuum, thereby lowering the vaporization point, and in

the same process, supplying a vehicle for the conveyance of the slightly mobile oil vapors. This law was discovered by Dalton and is one of the beacon lights of physical science. It is Nature's answer to the question: "Should steam be used as one of the factors in the distillation of oil from shale?"

THE DISTIL A CONTRIBUTION TO SUCCESS OR FAILURE

The requirements of the distil are many and very exacting, and on the merits of his distil the operator will travel toward success or failure. All compounds of commercial value must be extracted from the shale in the distil or go into the discard ash. The temperatures for the three grades of distillates must be uniformly maintained, and the shale charges transferred to the regional sections as required. Steam will contribute as one of the factors of the successful distil and be let into the charge at the most advantageous point. The successful distil will be capable of such a wide range of manipulation that it will be of small moment to the operator whether the charge is composed of dry paper shale or of the agglomerative variety. Efficiency and tonnage capacity must characterize each step in the process. The distil of intermittent action, with its accompanying loss of time, heat, and labor in charging and discharging, cannot keep the required commercial pace. It must be of continuous action in the charge and discharge of shale.

THE FOLLOWING ORES are mined in Finland, or prospecting work concerning them is carried on: Copper, pyrite, magnetite, galena, and molybdenite. The principal copper mines are at Outokumpu, on Lake Ladoga, and at Orijarvi, west of Helsingfors. There are iron mines on Lake Ladoga, and at Jussaro, on the coast west of Helsingfors. The Director of the Geological Survey of Finland states that there are extensive deposits of iron ore in Lapland. Finland's iron ore is not of the best quality. Pyrite is mined in Sotkamo, and at Otravaara. The molybdenite prospecting pit lies at Matasvaara, south-east of Nurmes. In the 'seventies gold was discovered in the north of Finland in the bed of the Ivaljoki, which empties into the Arctic. Gold washing since then has taken place regularly, but with inconsiderable results. Only small quantities of ore were produced in 1918 because of the War and the high cost of labor. At Outokumpu, 12,000 tons of copper ore was mined; at Pitkaranta, 3000 tons of magnetite; at Tipasjarvi, 800 tons of iron pyrite; and at Otravaara, 1000 tons of iron pyrite. Prospects are good for mining copper at Outokumpu, where there is a large orebody containing 6,000,000 to 8,000,000 tons of ore with 4% of copper and 27% of sulphur.

GRAPHITE is the most important of the developed mineral resources of Ceylon, the mines having a normal capacity of approximately 30,000 tons per year. Other products mined are gems, salt, mica, and monazite sand, the two last being of minor importance. No mineral oils have been found, nor have any geological surveys discovered petroleum deposits on the island.

Neutralizing Mine-Waters on the Rand

By F. WARTENWEILER and E. H. CROGHAN

*The problem of neutralizing mine-water on the Rand has received a certain amount of attention, and has, at a number of mines, been dealt with in an efficient manner. It should be noted that the metallurgist is interested because most of the replenishing or make-up water for the mill circuit, particularly during the dry season, is water pumped from underground. He is also called upon in many cases to treat the precipitated sludge for gold recovery. Neutralization of mine-water and the study of the sludge formed thereby are so closely related that they must logically be considered together.

The formation of acid in the mine-waters, due to oxidation of the pyrite constituent of the banket and surrounding country rock, is well known and need not be especially enlarged upon here. Aside from organic compounds, arising from decomposition of timber and occasional pollution by underground sewage, the following constituents are generally contained in mine-water: free sulphuric acid, soluble silica, ferric sulphate, ferrous sulphate, aluminum sulphate, and the sulphates of calcium, magnesium, and alkalis, together with chlorides.

In the treatment of the acid mine-water the following four objects may be held in view:

- (1) The efficient and economic neutralization of the free acid (sulphuric) and of the acid ferric sulphate, to prevent pipe and pump corrosion.
- (2) The settlement underground of the solids suspended in the water so as to deliver reasonably clear water to the pumps in order to avoid excessive abrasion and choking of pipe-lines.
- (3) The complete neutralization of free acid, precipitation of ferric and ferrous sulphate and sulphate of magnesium, and settlement of the precipitated salts to render the water suitable for use in the reduction works.
- (4) Neutralization of the free acid accompanied by settlement or filtration, to render the water suitable for use and re-use in underground spraying and washing in accordance with government regulations.

The following example illustrates the difference from a metallurgical standpoint of the effect of inefficient and efficient mine-water treatment:

A rather objectionable, unsettled, and partly neutralized water delivered by the underground pumps for reduction works purposes on a Central Rand mine gave the following incomplete analysis:

(a) Free acid (in terms of sulphuric acid).....	0.008%
(b) Total suspended matter	0.357%
(c) Ferrous oxide in solution	0.005%
(d) Ferrous oxide contained in (b) 5.70%, which is equivalent to 0.020% on the original water.	

This partly neutralized water with its suspended matter, on contact with cyanide solution, resulted in a loss of 2.58 lb. KCN per ton of water. On rendering alkaline to phenolphthalein and filtering, the cyanide consumption was nil.

The neutralizing reagents in current use on the local mines are carbonate of soda (Na_2CO_3), unslaked lime (CaO), slaked lime [$\text{Ca}(\text{OH})_2$], and pulverulent carbonate of lime (CaCO_3).

SODA. The soda used until recently has been in the form of crude soda obtained from a natural deposit in the Pretoria district, containing 60% of Na_2CO_3 , the balance being chiefly water of crystallization and detritus of the deposit. It effects the neutralization of the free acid, the precipitation of the iron salts ultimately as hydrated oxides, and sulphate of lime as carbonate, but leaves the cyanide hydrolizer, magnesium sulphate, incompletely precipitated under working conditions, that is, in the cold. In the past crude soda has generally been added only in sufficient quantity to obtain the first object, namely, to prevent pipe and pump corrosion. Incrustations in the pump columns have not been formed to a serious extent.

CALCIUM CARBONATE. This reagent is a natural pulverulent form of carbonate of lime, found in extensive deposits in several parts of the Transvaal. Examination of a representative sample shows a CaCO_3 content of 90%, grading 91% passing a 200-linear mesh screen.

According to small-scale tests, the first step, (1), cannot be carried out with this carbonate of lime to quite the same degree of neutralization without the use of a large excess of reagent and a contact extending over considerable time. With a 50% excess over theoretical requirement, 89.5% of the free acid and ferric sulphate was neutralized in 15 minutes. More time should evidently be given to render the water neutral to methyl orange. If it is safe to pump water slightly acid, then less CaCO_3 may be used. With a 10% excess, 82% of the free acid and ferric sulphate was neutralized in five minutes contact. When lime is used, the reaction is much quicker, the water becoming neutral to methyl orange in five minutes, using 10% excess. This is a matter of considerable importance, bearing in mind the natural tendency for undissolved reagent to settle out quickly in the sumps, and so to be rendered of little further use. For step (2) calcium carbonate shows an initial settling rate somewhat faster than lime, but with less degree of clear settlement. For step (3) it is not as suitable as lime, as it does not precipitate the ferrous salts.

LIME. The neutralization of the free acid and acid ferric sulphate can be obtained with lime, preferably with hydrated air-separated lime. Only sufficient should be fed, so that in testing the treated water with methyl

*Abstracted from a paper in the Journal of the South African Institution of Engineers.

orange indicator, the pink tint due to free acid and ferric sulphate is at the turning point to neutral. An excess of lime beyond this point will react with ferrous and magnesium salt in solution, precipitating them, and the third step, (3), is effected partly or completely according to the excess of lime added. For economic reasons and to avoid the risk of forming incrustations of calcium sulphate in the pump column, it is generally considered preferable to neutralize free acid and acid salts, (1), only, underground. At most mines it is considered safe to carry the destruction of acid not quite to the neutral state.

The settlement of the suspended solids, (2), is not affected detrimentally by the use of lime. Settling tests show that the initial settling rate is the same, using lime or soda, assuming like liquid-solid ratios. The settling rate is the most favorable with the water in an acid state, probably because there are no precipitated flocculent hydrated oxides in suspension, and the acid state supplies a condition of electrolyte favorable to settlement.

An excess of lime beyond that necessary to neutralize the free acid and acid ferric sulphate, tends to increase the bulk of the solids settled. This is usually an objectionable feature owing to lack of settling space underground. It appears impracticable to obtain water free from suspensions by settlement only in underground sumps, and some sort of filtration is required, supplementing settlement.

For reduction works purposes, the portion of the mine-water used in the replenishing of the mill-water circuit should not only be completely neutralized, but further purified, (3), that is, in addition to the free acid being neutralized and ferric sulphate precipitated, the ferrous salts and magnesium salts should be precipitated and then settled in a tank or a dam on the surface. For this, the use of lime is most economical. Where all the mine-water runs into the mill storage-water dam, sufficient lime from some source should be added to effect the above efficiently. The approved practice is to treat only such a volume of water as is necessary for surface services. The end-point test used for this treatment, (3), is a pink coloration with phenolphthalein indicator. The complete removal of ferrous and the efficient removal of magnesium salts is necessary to prevent the decomposition of cyanide. The action of the lime is to precipitate the ferrous, ferric, and magnesium salts as hydrated oxides. The ferric and magnesium hydrates are without effect on cyanide, but the ferrous hydrate must be removed. The lime assists the settlement, and the ferrous hydrate is in time oxidized to harmless ferric hydrate. The large surface exposed to sunlight and atmospheric agency in dams has undoubtedly a beneficent effect through the absorption of air.

UNDERGROUND SETTLING. With reference to underground-settling sumps, little has been known of the relative volume and weight of precipitates thrown down by the neutralizing agents, sodium carbonate, and hydrated air-separated lime. At the suggestion of the manager, to whom the matter was of considerable importance, com-

parative tests were made on untreated acid mine-water from the Durban Rondepoort Deep mine with a view to gaining knowledge on these points. A record of these tests, comparing sludges formed by soda and by lime, is as follows:

Two portions of the untreated water were exactly neutralized to the methyl orange stage (neutralization of free acid and ferric sulphate, and considered sufficient for underground purposes) with sodium carbonate and lime respectively. The volumes occupied on complete settlement and the weight of the ignited precipitates were:

	Volume cc.	Weight gm.
(a) With sodium carbonate	10.0	0.092
(b) With lime	10.5	0.097

Neutralizing two other portions to a point midway between the methyl orange and phenol stage, results are:

	Volume cc.	Weight gm.
(c) With sodium carbonate	30	0.13
(d) With lime	29	0.126

Neutralizing two other portions completely (to the phenolphthalein stage) results are:

	Volume cc.	Weight gm.
(e) With sodium carbonate	23	0.176
(f) With lime	38	0.173

These tests indicate that the volume and weight of precipitates to the methyl orange stage of neutralization (a) and (b) are practically identical. The same holds with the midway, (c) and (d), stage. Beyond this, neutralization is not apt to be carried underground. When the water is completely neutralized, (e) and (f), or to the phenolphthalein stage, the volume evidently favors the use of sodium carbonate, although the weights remain nearly equal. Where the acid content of the water is high, calcium sulphate (when lime is used) may be thrown out of the supersaturated solution and augment the volume and weight of precipitates. With soda, sodium sulphate, owing to its high solubility, would not be deposited.

RATE OF SETTLEMENT. Comparing the rate of settlement of sludge when using soda and when using lime, we have noted the following:

When neutralizing to methyl orange settlement is at equal rates, the tendency being for suspensions to remain. Neutralizing to the midway point, soda gives slightly faster settlement. When neutralizing completely the settlement rate is distinctly in favor of soda. The soda, however, does not give such a clear settled water as lime, suspension remaining. It should be noted that the rate of settlement of the sludge is in all cases much slower than that of banket-ore slime.

CYANIDE TREATMENT OF SLUDGE. Experiments were conducted on a typical sludge from the City Deep mine with the view to studying a practical method of handling, and of the subsequent recovery, of the gold content in the cyanide process. No difficulty was experienced in making a good vacuum filter-cake from $\frac{3}{4}$ in. to $2\frac{1}{2}$ in.

thickness. On account of the gelatinous nature of the sludge the residual moisture in the cake, however, remained as high as 43% and was rather soft and smeary. Using a pressure-filter press, a 2-in. cake was made in 10 to 20 minutes with a thickened pulp of from $\frac{1}{1.7}$ to $\frac{1}{5}$ solid:liquid ratio. After air drying in press for 20 minutes a hardened cake, easy to handle or transport, containing only 25% moisture, was obtained. This cake would seem to meet practical requirements.

Cyanide-extraction tests on this sludge, 99.9% of which passed a 200-mesh screen, and which assayed 1.02 dwt., disclosed interesting information. Air-agitation cyanide-treatment of the sludge taken from the sump yielded only 46% extraction, with a prohibitive cyanide consumption. The presence of deleterious reducing organic matter and ferrous salts was indicated. Similar extraction tests made on the partly air-dried filter-press cake yielded a 90% extraction with a nominal cyanide consumption. Analysis of the effluent solutions from this last test established the oxidation of the ferrous iron to the ferric state, due to the press aeration.

Filter-presses have been installed underground in a few mines, and the press cake is hoisted with the ore. In other mines the sludge is bailed out with skips, and is dumped and run into surface dams for oxidation and possible future treatment. The low gold content (the pure precipitated sludge carries no gold), due to an admixture with fine from stope washings, in many instances precludes future treatment. The great dread, from a metallurgist's point of view, is the practice of dumping skiploads of slushy sludge into the 'fine' bins for direct transport to the mill. The ill effect on conveyor-belts, mill-feeders, battery-floors, and foundations can readily be imagined, not to mention the dismay at the slime-plant with the resultant poor settling and high cyanide consumption.

In concluding we wish to repeat that there is much important work still to be conducted on mine-water treatment in the consideration of which the engineer, the metallurgist, and the chemist are mutually concerned.

Helium

Until recently hydrogen has been practically the only gas used for filling balloons. As far as buoyancy is concerned, it is the ideal gas for this purpose, as it is the lightest of known substances. On the other hand, however, hydrogen is extremely inflammable, and before the War had progressed very far it was discovered that airships filled with it were so easily destroyed by incendiary bullets that such craft could be used only where they could be effectively protected from attack by this weapon. The officers responsible for the air-service activities of the belligerent countries had been continually seeking for some non-inflammable substitute for hydrogen, but the various attempts made to utilize non-inflammable gases in balloons were unsuccessful on account of their relatively great weight. Then the possibility of obtaining helium in

practicable quantities appeared and investigation looking to the development of a supply was begun.

Helium is next to hydrogen in buoyancy. Its weight is but twice that of hydrogen, so that in balloons, compared with the far heavier enveloping air, it exerts a lifting power of about 92% of the lighter gas. Since it is also absolutely non-inflammable, it is an all-round ideal balloon gas. Helium was first found in natural gas in Kansas in 1907. Very soon after the United States entered the War the Army, Navy, and Bureau of Mines became interested in the project of obtaining it from this source for the use of the lighter-than-air service of the United States. This work was considered of the first importance on account of the great tactical advantage which the allied forces would possess if equipped with aircraft so vastly superior to those of the enemy that attack by the latter would prove extremely hazardous, if not almost useless.

What has been said above relates but to one of what may be many important uses of helium in war and in peace. Up to recently the amount produced was so minute in quantity that helium was not much more than a laboratory curiosity. Therefore its range of properties and the consequent possibilities for its useful application in science and the arts could not be fully determined and developed, and only recently has much research work been attempted. The price paid for helium before the entry of the United States into the War was approximately \$1700 per cu. ft. It is probable that not over 100 cu. ft. had been isolated up to that time. After our entry into the War three experimental plants for the production of helium from natural gas obtained from the Petrolia pool, at Petrolia, Texas, were erected. Two of these, known as plants 1 and 2, were built at Fort Worth, the gas being supplied through a pipe-line from the former place, and the last plant, known as plant No. 3, was established at Petrolia. During the operation of these plants approximately 225,000 cu. ft. of helium was separated from the natural gas, this helium being contained in mixtures varying from 60% to 92% purity. While helium of 92% purity is suitable for use in balloons, that of lower purity must first be brought up to approximately this percentage before it can be so employed.

The cost of producing 1 cu. ft. of helium in a mixture of 92% purity in plant No. 1, the most successful plant to date, was about 39c. This shows an extremely remarkable reduction in the price of producing helium, especially when the fact that this was an experimental plant and was not of such proportions as to give lowest cost is taken into consideration. The cost of producing helium in the latest production plant, as estimated by the Navy Department, which is in charge of its construction and operation, is 5.22c. per cubic foot.—U. S. Bureau of Mines.

THE importance of the copper industry to Peruvian prosperity is brought out by the fact that roughly one-third of Peru's exports consists of copper.

Magnetic Separation of Bismuth, Tin, and Tungsten Concentrates in Tasmania

By WM. E. HITCHCOCK and J. R. POUND

*At the Launceston works of the S. and M. Syndicate, Wetherill magnetic separators are used, with accessory appliances for crushing and screening the concentrates to be treated. The concentrates are mixtures of heavy minerals not further separable by the ordinary wet-mill operations on account of their similar specific gravities. They are first crushed, as necessary, in rolls, and screened when dry through a set of shaking-screens until the whole is divided into four sizes, ranging from one-eighth of an inch in diameter downward. Each size is then treated on a magnetic separator.

The essential feature of the Wetherill magnetic separator lies in the passage of the feed on a conveyor-belt through the magnetic field between a flat pole and a V-shaped pole of opposite polarity. In such a magnetic field the magnetic particles are attracted toward the V pole from all positions except those in the immediate neighborhood of the flat pole. The machines in use at Launceston have two sets of magnets. Each set consists of two electro-magnets—the one with two V poles above the conveyor-belt and the other with two flat poles which are below the belt and opposite to the V poles. Each pair of electro-magnets is connected in series, and by regulating the strength of the electric current the lifting power of the set can be adjusted. The first pair of electro-magnets is used to pick up the strongly magnetic minerals, such as magnetite, and the second pair is used to pick up the feebly magnetic minerals, such as wolframite; the first pair forms a weak and the last pair a strong magnetic field. The dry concentrate is fed uniformly on to the conveyor-belt, which passes on top of the four flat poles and beneath the four V poles. The minerals attracted to a V pole are removed by an endless cross-belt moving just beneath it and at right angles to the conveyor-belt. As these magnetic particles pass out of the magnetic field they fall into a chute and a bin at the side of the machine. On these machines there can thus be collected from the four V poles four magnetic products, but generally those from the first two V poles form one product and those from the last two form the second product. These machines take an electric current of 20 amp. at 110 volts, each machine being provided with a d.c. generator and with appliances for regulating the current. The two generators and the whole plant are driven by a 14-hp. motor supplied with three-phase alternating current by the Launceston Corporation.

The conditions necessary for the satisfactory working of these Wetherill separators may now be summarized:

these conditions also hold in general for other magnetic separators. The first essential for good working lies in the close sizing of the feed. The magnets are brought as close as possible to the material, so as to obtain the full benefit of the magnetic fields. It is evident that large differences in the sizes of the particles of the material being treated must lead to uneconomical handling of the finer portion, which could be better treated by itself. An even distribution of the particles over the conveyor-belt, which takes them past the magnets, is clearly desirable, and is ensured by means of a suitable feeding device. At the Launceston works a shaking-bar feeder is used, which moves with a set stroke at a given distance beneath a slot in a hopper bottom. Both length and time of stroke of the bar are capable of close regulation as well as the distance from bar to slot, and thus any size and variety of material may be fed as desired on to the conveyor-belt. The speed of the cross-belts, which take the magnetic particles from beneath the magnets to the side chutes of the machine, needs to be sufficient to carry the particles clear of the magnet; a speed of about 300 ft. per min. is usually ample.

The speed and width of the conveyor-belt are both important, as they largely fix the capacity of the machine. The width must not be too great, because the wider the belt the larger the air gap necessary between upper and lower poles, due to the increased space required between the conveyor and the cross-belt to allow the two streams of ore to pass. Consequently, the wider the belt the more electric energy is required to remove the same amount of any given mineral. Here, again, the magnet construction will be more difficult, for, apart from the above considerations, the amount of magnetism must be at least proportional to the width of the belt, and this must be produced by longer or thicker coils or by greater current-strength. There is a practical limit to each of these factors, so that the maximum width of conveyor-belt made on Wetherill separators used for feebly-magnetic minerals is 18 in. In the Syndicate's machines the magnet poles are 14 in. wide, the conveyor-belt being a little wider. The speed of the conveyor-belt cannot be increased beyond a certain point if the quality of the separation is to be maintained, as a magnetic mineral must remain a definite time beneath a pole in order to be attracted to it—the larger the mineral particle the longer the time. For this reason fine material may be treated with a faster conveyor-belt speed than coarse, assuming the material is one layer deep in each case. However, the actual rate of treatment does not increase indefinitely as the size diminishes. The best size of material to treat

*Abstracted from the proceedings of the Australasian Institute of Mining Engineers.

with this type of machine is, generally speaking, minus 10 and plus 20-mesh, averaging 0.04 in. diameter. A device to vary the speed of the conveyor-belt is an advantage, as then re-treatment of the supposed non-magnetic tailing from the machine may always be avoided. The greater the amount of magnetic material in the feed, the slower it must pass beneath the magnets, otherwise the percentage of magnetic material in the tailing will increase. Such a slower feed can best be obtained by thinning out the material on the belt and by decreasing the speed of the belt. The conveyor-belt speed should be capable of variation (by steps) from about 50 ft. to about 100 ft. per minute.

The capacity of a Wetherill magnetic separator depends on:

1. The width of the magnet poles, and thus of the conveyor-belt.
2. The speed of the conveyor-belt.
3. Thickness on the belt of the layer of particles, and the size of the latter.
4. The strengths of the magnets and their number.
5. The nature of the separation desired.

It has been shown above that increase in each of the first four factors favors increased capacity, but that these factors cannot be raised above a certain limit. In practice there is effected a compromise between the development of each of these factors, a compromise largely decided by the fifth factor, which is, of course, the most important feature of any given machine.

In the case of mixtures of bismuth or tin minerals with wolframite, the treatment of which represents the greater part of the Launceston work, it is desired to obtain complete separation of the valuable minerals from one another, quite apart from the fact that penalties may be imposed on the seller of mixtures of these minerals. The Syndicate is here working under the severest conditions, and that at once precludes any record-breaking capacities. For example, users of Wetherill machines that are separating ferruginous zinc-blende (ZnFe)S, from galena, PbS, are satisfied with zinc and lead products that contain appreciable impurities, for example, a lead product assaying 50% Pb and 5% Zn, and thus it pays them to obtain capacity at the expense of completeness of separation. It is found that figures quoted from American practice on the capacity of Wetherill separators treating such ores are far in excess of those obtained at Launceston in separating concentrates containing wolframite. In the present case the quality of the separation comes first, the aim being to maintain the highest grade of products possible with any given ore, and it will be sufficient to indicate that on an average cassiterite-wolframite concentrate the rate of treatment of one machine is about three-quarters of a ton in 24 hours.

These Wetherill separators are simple to operate, easy to regulate and to clean, and the magnetic fields can be finely adjusted. The feed must be perfectly dry and of appropriate size. These machines are not suitable for slime—that is, say, material passing through a 150-mesh sieve, for such material sticks to the conveyor and cross-

belts and is carried round with them past the proper bins. Also, in falling into the various chutes and bins the slime creates dust. For slimy ores a magnetic separator that will treat the wet material is required.

There will now be considered the results obtained with these Wetherill separators on the concentrates from the S. and M. mine, Moina, Tasmania. The run-of-mine ore is there treated in a typical wet mill, from which two main grades of concentrates are forwarded to Launceston. These are known as 'firsts' and 'seconds', the former being the better product.

The S. and M. 'firsts' contain mainly bismuthinite, cassiterite, and wolframite, which are the minerals of economic importance, and together make up about 98% by weight of the concentrate. The remaining 2% by weight consists of pyrite, magnetite, scheelite, and silica. The S. and M. 'seconds' contain all the above minerals in quantity, together with small amounts of chalcopyrite, molybdenite, siderite, and other minerals. In connection with the following data approximate average results alone can be given, as the concentrates are continually changing in details, though their general characters remain the same. For instance, in the S. and M. 'seconds' the amounts of pyrite and magnetite vary considerably, and in both 'firsts' and 'seconds' the ratios bismuthinite: wolframite: cassiterite are constantly altering.

The S. and M. 'firsts', on treatment with the magnetic separators, give a little magnetite product from the first two V poles, those of the weak electro-magnet, then a wolframite product from the last two V poles, those of the strong electro-magnet, and finally a non-magnetic product of cassiterite and bismuthinite, with small amounts of scheelite, silica, and pyrite. The magnetite product contains a little magnetic pyrite and merely traces of the valuable metals. The wolframite product averages about 73% WO_3 , with 0.7% Sn, and the merest trace of Bi, while the tin-bismuth product assays in general about 63% Sn and 4% Bi, with 2% WO_3 or more, depending on the amount of scheelite present. These last two products are sold, the wolframite at present to the British government, and the tin-bismuth product to an English chemical works, where the bismuth is extracted, and the tin residue then taken by a tin-smelter. At present the magnetic separation process gives the following results from the 'firsts':

	Weight	Assays			Recoveries		
		WO_3 %	Sn %	Bi %	WO_3 %	Sn %	Bi %
Iron minerals	0.5
Wolframite	42.5	73.0	0.7	...	96.9	0.8	...
Tin-bismuth minerals	57.0	2.0	63.0	4.0	3.1	99.2	100
Original 'firsts'	100.0	36.5	36.2	2.3	100.0	100.0	100

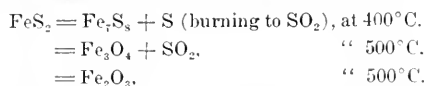

Scheelite is an undesirable mineral in the feed, as it means the presence of tungstic acid (WO_3) in a non-magnetic form, which therefore cannot be separated from the tin-bismuth product by magnetic separators.

The S. and M. 'seconds', on treatment by the magnetic separators, give three products. The first product consists of magnetite and magnetic pyrite, the former mineral predominating. The major portion of this product comes from the first V pole, and is almost wholly mag-

netite, while from the second V pole comes the minor portion, which contains the bulk of the magnetic pyrite. The magnetite occurring in the S. and M. concentrates contains some rock minerals intimately associated with it, but it is still quite strongly magnetic. This iron-product contains very small amounts of the valuable metals, and is removed as waste. The second product from the machining of the 'seconds' contains wolframite with considerable magnetic pyrite and smaller amounts of siderite and garnet or vesuvianite. The third, or non-magnetic product, contains bismuthinite, cassiterite, pyrite, scheelite, silica, etc.—that is, all the non-magnetic minerals present in the original 'seconds'. This product may contain over 50% by weight of pyrite. The pyrite in the S. and M. 'seconds' thus varies in magnetic quality, although the bulk of it is non-magnetic.

The pyritic wolframite and the pyritic tin-bismuth products from the machining of the 'seconds' are both of too low a grade to send direct to market. Advantage is now taken of the fact that pyrite may be converted into strongly magnetic sulphide and oxide of iron—approximately Fe_2S_4 and Fe_3O_4 —by means of a partial roast. The above two products are thus separately roasted, cooled, and then again treated on the Wetherill machines, when the strongly magnetic roasted iron pyrite is removed by the first weak electro-magnet, leaving the wolframite or the tin-bismuth product to be recovered later from the machine as a high-grade product.

The roasting of pyrite for magnetism is a fairly common operation being adopted on a large scale in the United States, chiefly in connection with the separation of pyrite from zinc-blende and galena, such mixtures being the middlings produced in the wet dressing of pyritic zinc and lead ores. Pyrite, on heating, deerepitates at 60°C . and commences rapidly to lose sulphur at 400°C . In the presence of air it thus ignites at the latter temperature, and it becomes incandescent at about 500°C . Pyrrhotite, with a composition usually about Fe_7S_8 , ignites at about 500°C . in air. The decomposition of pyrite on roasting may be represented as follows:

The final oxide of iron obtained will depend on the conditions. Free access of air and temperatures from 500° to 1100°C . approximately favor formation of ferrie oxide, while a limited air-supply, the presence of reducing gases (CO , H , SO_2), and extremely high temperatures lead to the tetroxide. The following table gives approximately the ignition temperatures in air of those sulphides that have a bearing on the roasting practice; the figures are taken from Friedrich's researches, as recorded, with references, in Hoffman's 'General Metallurgy' (1913). The ignition temperature of a sulphide, however, varies with the conditions of the test, and especially with the size of the sulphide particles tested. The following figures refer to very fine ore, 0.006 in. diameter, approximately.

Ignition Temperatures in Air of Various Sulphides

Pyrite, FeS_2	400 C	Molybdenite, MoS_2	500 C
Pyrrhotite, Fe_7S_8	500 C	Chalcocite, Cu_2S	550 C
Ferrous sulphide, FeS	500 C	Bismuthinite, Bi_2S_3	600 C

In roasting pyrite for magnetism the aim is to get a product of uniform magnetic quality, which will consist of magnetic sulphide and oxide of iron. The larger particles, after roasting, will contain a kernel of unaltered pyrite, then a layer of magnetic sulphide, and on the outside a coating of magnetic oxide. The finer particles of roasted ore will be practically wholly magnetic oxide. Coarse ore takes a longer time to roast to a required magnetic quality than fine ore, and the ore should therefore be carefully sized before roasting. It should all pass through a 10-mesh sieve. Material of half this size, and less, behaves better as regards the roasting, but then the extra crushing and the behavior on the magnetic separators would become serious items. It is the Launceston practice to crush the 'seconds' into three sizes, from 0.05 in. diam. downward, each size being subsequently treated by itself.

At the works in Launceston the closely-sized products are roasted in a small muffle furnace, and are rabbled by hand. Air is admitted in limited quantity through the door of the muffle and the gaseous products of the roasting—sulphur and sulphur di-oxide—pass out at the farther end of the muffle and into the chimney. The cast-iron muffle is heated by a wood fire placed at one side, and the flame passes around it and then up the chimney, the draught of which also causes the air-current through the muffle. The ore-charge is about 2 in. deep, and is rabbled from 4 to 6 times per hour. The average time of roasting a charge, approximately 1½ cwt., is 1½ hours, or the mean rate of roasting, all S. and M. pyritic products being considered, is ¾ cwt. per hour. This is neglecting the time taken to heat the furnace on Monday morning in each week, which is about 6 hours. The furnace thus treats 5½ tons of ore per week of six days, with a fuel consumption of 8½ tons (1 ton = 80 cu. ft.) of firewood. This type of furnace is only suitable for small tonnages, such as are dealt with, and is thus expensive compared with larger installations with mechanical feeding and rabbling. The cost of roasting amounts to approximately £2 15s.* per ton of concentrate roasted, this being largely dependent on the life of the muffle. A good muffle ought to last out the roasting of 100 tons of pyritic ore. The great advantage of this type of furnace is that the dust losses are reduced to a minimum. The results obtained are satisfactory, as the end-point of a roast can be judged with accuracy, and small variations in the temperature, rabbling, time of roasting, and quantity and quality of the ore roasted can thus be arranged so as to compensate each other. When finishing the roasting of a charge of ore the muffle is at a good red heat, say at 650°C . If the temperature is lower the roasting takes too long; if higher the various ore-particles frit together excessively, and the subsequent magnetic separation is adversely affected.

*\$10.40 at the present rate of exchange.—Editor.

When the roasting is approaching completion, the charge should throw off very few sparks on rabbling. During the early stages of the roast this sparking of the charge is pronounced; it is due to the decrepitation of the pyrite and the incandescence of the rapidly burning particles that are thrown up from the surface of the charge. At the end of the roast the ore will appear uniformly red hot, and will give a short flame on rabbling, not a long flame as when half done. The cold-roasted ore should be dull gray-black in color, with no shiny particles of unaltered pyrite. Only the surface should show a reddish-brown tint, due to further oxidation to ferric oxide; if there is a red-brown tint throughout, the charge is over-roasted. Ferric oxide is feebly paramagnetic, and the aim is to form the strongly paramagnetic compounds of iron. However, in practice over-roasting rarely occurs. If the ore is under-roasted, then bluish-black particles will be seen. These bluish particles contain large kernels of unaltered pyrite, and are thus only weakly magnetic. The roasted ore-particles should be very slightly sintered together. Any marked sintering or fritting together of the ore is due to the temperature or time of roasting being too great. Any sign of fusion of the bismuthinite points to the same error, which, however, with ordinary care is easily avoided. A sample of the ore may always be removed from the furnace, rapidly cooled, and examined. Under-roasting is the main thing to guard against, especially if the ore is coarse and rich in pyrite. It is generally safer to give the ore a quarter of an hour longer in the furnace if there is any doubt. In practice any lot of uniformly sized ore will have a constant time of roasting under normal conditions.

Besides the magnetic separation of its own concentrates, the S. and M. Syndicate also undertakes similar work on concentrates from other companies. These concentrates fall into two main classes:

1. Concentrates containing wolframite together with tin and bismuth minerals.
2. Concentrates containing cassiterite with valueless magnetic minerals, such as titaniferous iron ore, chromite, and magnetite.

With the first class the completeness of the magnetic separation is largely dependent on the number of associated particles present. For instance, concentrates from the All Nations mine, Moina, Tasmania, give a clean wolframite product, assaying often over 74% WO_3 , with the merest trace of Bi, the non-magnetic product consisting of bismutite, bismuthinite, and a little native bismuth, together with pyrite, silica, etc. Another example of an ideal mixture for magnetic separation is the ore from the Iris mine, Moina; the wolframite product from this ore averages 73% WO_3 , with very little tin (0.1%), while the tin product assays 73% Sn, 0.1% WO_3 . In other cases, owing to the presence in the ores of magnetic minerals such as siderite or monazite, the grade of the wolframite product is lowered. This is not so bad as when tin or bismuth minerals pass into the wolframite product, due to their association with magnetic minerals, such as the wolframite itself, magnetic

pyrite, or oxides of iron (hematite, limonite). The S. and M. concentrates suffer in this way to some extent. Certain bismuth-tungsten concentrates from New South Wales and Queensland contain wolframite much coated with bismutite, and their separation is thus imperfect. Indeed, the actual behavior of an ore on treatment by the magnetic separation process can only be exactly determined after a trial sample has been so treated. The actual testing of a few pounds weight of the material under consideration is a simple matter, and this will give definite data concerning the possible magnetic and non-magnetic products, which determine the economical aspect of the business.

In the second class of concentrates there is only one valuable mineral to be recovered. These low-grade tin concentrates come from the north-eastern districts of Tasmania, and contain cassiterite along with ilmenite, spinel (pleonaste), chromite, magnetite, monazite, etc. These last minerals have fairly high specific gravities, and are thus not economically removable from the tin ore by wet-dressing; they are, however, magnetic, and are easily removed by the magnetic separators. Thus the cassiterite is obtained along with the other non-magnetic minerals, such as quartz, zircon, and non-magnetic spinel. (Spinel, essentially $MgAl_2O_4$, has a weakly magnetic to a non-magnetic character, according to the amount of iron present in the mineral; its color varies similarly, the highly ferruginous variety, pleonaste, being the tin-miners' 'black-jack'.) The raising of the grade of the tin concentrate by the magnetic separation process obviously depends on the amount of magnetic material removed, and the final grade of the resulting tin product on the amount of the non-magnetic material present. It is quite common to remove as magnetic material from one-half to two-thirds by weight of the original concentrate, thus raising the grade by 100 to 200%; for example, from 30% Sn or 20% Sn to 60% Sn. The resulting high-grade tin concentrates are readily accepted by the neighboring smelting works of the Mount Bischoff Tin Mining Company.

KWANTUNG PROVINCE, CHINA, is turning out over 5% of the entire world production of bismuth, and the deposit is being worked by Chinese coolies, armed with native grass hooks, and two large enameled basins each, according to an issue of the 'Eastern Commerce'. Shipments of bismuth from Hongkong from January 1 to August 1, 1919, amounted in value to about \$100,000, of which approximately 60% went to Great Britain and the rest to the United States.

MANGANESE ORE accounted for 95% of the ore exports from India in 1918. The shipments decreased by nearly one-third to 433,300 tons. About 72% of the total quantity went to the United Kingdom, and the remainder to France, the United States, Japan, and Italy. Almost all the wolfram ore exported (4782 tons) was shipped from Burma with the exception of 38 tons from Bengal. The United Kingdom took the total quantity shipped.

Speech by Mr. Hoover Before the Western Society of Engineers, at Chicago, on February 28

I believe that I appear before an assembly of engineers in two aspects: first, as a fellow engineer of some experience in industry; and, second, in the aspect of a citizen of some experience in food problems. I propose, on this occasion, to discuss the inter-relationship of general industry and food production and distribution, particularly as to the necessity of a fair balance between general industry and agriculture, and the need to maintain this balance by securing to the farmer more economy in the distribution of his products. There are not only engineering problems involved in this relationship, but there are in addition great social and political issues of the first importance.

In order to avoid repetition of long phrases, I propose to use the term 'agriculture' as referring to the agricultural industry, and to use the term 'industry' as limited to the production and manufacture of non-food materials.

The outstanding feature of civilization during the last century has been the increasing growth of industry as distinguished from agriculture. Many States have stimulated this side of national life until they have built up their populations far beyond the capacity of their land. We have the most profound instances of this in England and Germany. In these States, the population is today dependent upon the import, mostly from overseas, of from 30 to 70% of different food commodities through the exchange of industrial products. The very life of their people is thus dependent upon maintaining open the free access to overseas markets. From this necessity have grown the great naval armaments of the world, and the burden that they imply on all kinds and classes of population. Such nations of necessity, have engaged in fierce competition for markets for their industrial products. They have thus built up the background of world conflicts. The titanic struggles that resulted have endangered the very lives of their people from starvation. Their war tactics have in large degree been directed to strangle food supplies.

One other result of this development has been the terrible congestion of populations in manufacturing areas. All such congested populations are periodically subjected to low standards of living, of housing, and other conditions of life that make for physical and moral degeneration. In times of industrial prosperity, the standard of living increases in these manufacturing areas, but in times of industrial depression they only maintain themselves by the practical sweating of the workers. Beyond this, there is another jeopardy which has received too little attention; in times of industrial depression, whether brought about by war or by the ebb and flow of world prosperity, these populations, oppressed

with misery, turn to political remedies for matters that are beyond human control. They naturally resent the lowering of their standards of living and they inevitably resort to industrial strife, to strikes, and disorder. Their productivity, upon which the very life of the nation depends, again decreases, and their ability to buy food from abroad decreases in train with their fallen productivity, because they decrease the production of goods to send in exchange. One other result of large industrial development is that in times of industrial prosperity when the standard of living rises in general industry, it attracts into its radius the agricultural population, and immediately creates inroads into agricultural production. To some extent this is a natural balancing of forces which tends to stabilize itself in time. But there are social and political phases more important than sheer economic balances.

Years ago our predominant export was food. Then we turned to importing months for an expanding industry and our net export food surplus diminished to a low ebb until the beginning of the War, when it received a special and temporary stimulus. By and large our industries have been in a high state of prosperity. More favorable hours, more favorable wages, are today offered in industry than in agriculture. The industries are drawing the workers from our farms. If this balance in relative returns is to continue, we face a gradual decrease in our agricultural productivity. If we should develop our exports of industrial commodities during the next five years as rapidly as we have during the past five years, we shall by that time be faced with the necessity to import foodstuffs.

Some economists will argue, of course, that if we can manufacture goods cheaper than the rest of the world and exchange them for foodstuffs abroad, we should do so. But such argument again ignores certain fundamental social and broad political questions. These dangers have become more emphasized by experience of the War. From dependence on overseas supplies of food, we shall, by the very concern that will grow in public mind as to the safety of these supplies, soon find ourselves discussing the question of dominating the seas. Our international relations will have become infinitely more complex and more difficult. Unless the League of Nations serves its ideal, we shall have to burden ourselves with more taxation, to maintain great naval and military forces. But of far more importance than this is the fact that the social stability of our country and the development of our national life depends upon our farms and villages. These are the sources that have always supplied our country with its true Americanism, its new and fresh minds, its physical and its moral strength. In-

dustry's real market is with the farmer; it benefits by an increase of his standard of living. We want our exports to grow in exchange for commodities we need from abroad, but we want them to grow in tune with our social and political interests, and to do so they must grow in step with agriculture.

Therefore, when we sit down to consider our reconstruction policies from the War—when we sit down to plan the future development of our country—our first thought should be of the state of our agricultural industry. For the last three months I have been a member of the Industrial Commission at Washington, endeavoring to find some solution for the conflicts and social wrongs that have grown up in our industrial community. Great as is the need for constructive thought with regard to its weaknesses, the need for similar thought and similar activity is still greater with regard to agriculture.

The prime problem is to make the agricultural industry economically attractive so that it draws into its service its full proportion of American life, so that it can keep pace with industry in its rapid development. When we come to the consideration of practical measures we soon arrive at two primary facts. The first is, the farmer's main production must find its market either in the great industrial centres along the Atlantic seaboard or, alternatively, in export to Europe. In either case, the prices in normal times are made primarily by competition with the other great sources of the world's food-supply. His prices are thus only remotely regulated by the cost of production. Strict economists will argue that if the prices are unprofitable to the farmer it will ultimately correct itself by diminished production and consequent general rise in the world-level of prices. Amid the complex flow of economic forces today, these results come very slowly and in the meantime the actual result is mainly a decrease in the standard of the farmer's living. For the farmer must plant and gamble in advance on the demand. He cannot decrease his production to meet such contingencies with the facility of organized industry. Whatever the economic argument may be, the outstanding fact is that for all practical purposes the farmer's level of prices is made by the world-prices of food as interpreted at the point of delivery, and during wide periods of time he is underpaid. On the whole he has not been underpaid during the War, but recently the tide has begun to turn against him.

The second great fact that would be developed is that the American farmer receives a less proportion of the consumer's purchase price for his product than the farmer in most other civilized countries; that is, the margins between the farmer and the consumer is the widest in the world. This margin comes partly out of the consumer, but predominantly out of the farmer, for, as I have said, the prices to the consumer in the great food commodities in normal times are fixed by world forces. If we assume the basis of price is not to be remedied, the line of practical remedy to the farmer lies in decreasing the cost of placing his products into the hands of the consumer. Every cent that we can decrease

this cost contributes to the consumer, but even more largely to the farmer.

If we analyze the weaknesses of our system of distribution, we can, for purposes of discussion, divide it into three phases: their transportation, their manufacture in preparation for the consumer, and the agencies of distribution.

Our transportation has been under continuous discussion for forty years with ever-tightening regulations. I believe the great majority of our people are opposed to nationalization. Nevertheless, I doubt whether there is anyone in the United States who is not completely seized with the necessity of rigorous regulation. We are about to return the railways to private ownership under generous terms and, as I have said elsewhere, private ownership is now on its final trial. The proprietors have now to demonstrate their initiative; that they can maintain a right relation to their employees; that they can maintain their administrative efficiency; that they can keep out of national and local politics; that they can conduct these operations in the sense of complete service to the community. If it shall fail in this latter respect, our people in reaction will probably be prepared to sacrifice something of its ideals in other directions, for the supreme test of efficiency is human service.

I wish to point out one weakness in our present railway situation as bearing upon the farmer. Everyone knows of the annual shortage of cars during the crop-moving season. Few people however appreciate that this shortage of cars often amounts to a stricture in the free flow of commodities from the farmer to the consumer. The result is that the farmer, in order to sell his produce, often unknown to himself, makes a sacrifice in price, owing to a local glut. The consumer is compelled at the other end to pay an increased price for foodstuffs, owing to the shortage in movement. In proof of this, on one occasion a study was made under my administration into the effect of car-shortage in the transportation of potatoes, and we could demonstrate by chart and figure that the margin between the farmer and the consumer broadened 100% in periods of car-shortage. Nor did the middleman make this whole margin of profit, because he was subjected to unusual losses and destruction and took unusual risks in awaiting a market. The same phenomenon can be proved at times of shortage of movement in corn and other commodities.

The usual remedy for this situation is insistence that the railways shall provide ample rolling-stock, trackage, and terminals to take care of the annual peak-load. This, however, imposes upon the railways a great investment in equipment for use during a comparatively short period of the year when many commodities synchronize to make the peak movement. It imposes a burden on the entire cost of transportation. This burden of extra equipment will probably always be held to such low dimensions that we will never escape the annual delays in transport and stricture in market. Aside from this question of a peak-load, we have no doubt fallen behind in the provision of even normal railway equipment during the War.

I would like, however, to recall another partial remedy for this situation advanced many times by our engineers. That is, the possible help from improving the waterways from the Great Lakes to the Atlantic seaboard by way of the St. Lawrence river so as to pass full sea-going cargoes. It has already been determined that the project is entirely feasible and at comparatively moderate cost. The result would be to place every port on the Great Lakes on the seas. Fifteen States contiguous to the Lakes could find an outlet for a portion of their annual surplus quickly and more cheaply to the overseas markets. The result would be to take off a considerable portion of the peak-load on the trunk-line railways during the great crop-movement season. It would contribute materially to reduce this effectual stricture in the free flow of the farmer's commodities to the consumers. Of far greater importance, however, is the fact that the costs of transportation from the Lake ports to Europe would be greatly diminished and this diminished cost would go directly into the farmer's pockets. It is my belief that there is a saving of five or six cents a bushel in the transportation of grain. Although a comparatively small proportion of our total grain production flows to Europe, I am convinced that the economic lift on this minor proportion would raise the price of the whole grain production by the amount of saving in transportation. The price of export grain in Chicago in normal times is the Liverpool price, less transportation and other charges, and if we decrease the transport in a free market the farmer should get the difference. Not only should there be great benefits to the agricultural population, but it should be a real benefit to our railways in getting them a better average load without the cost of maintaining the surplus equipment and personnel necessary to manage the peak-load during the fall months. It has been computed that the capital saving in rolling-stock alone would pay for the entire cost of this waterway improvement over a comparatively few years.

The matter also becomes of national importance in finding employment for the great national mercantile fleet that we have created. In other words, instead of expending vast sums on the development of our tracks, rolling-stocks, terminals of the trunk-line railways, we should effectually substitute the other arm of transportation which we have already built, that is, our fleet.

Another factor in transportation bearing upon the problem of marketing is the control by food-manufacturing and marketing concerns of refrigeration and other special types of cars. This special control has grown up largely because, owing to seasonal fluctuations over different roads, no one railway wished to provide sufficient special cars and service for general use by all manufacturers. The result has been to build up the domination of certain concerns and stifle free competition. Much the same results have been attained by special groups in control of stockyards and, in some cases, of elevators. Where such formal or informal monopolies grow up, they are public utilities and if the farmer is to have a free market they must be replaced by constructive public service.

The second point of attack in reduction of the cost of marketing farm produce lies in the insistent removal of every impediment to free trade in produce. We have some commodities where manufacture has grown into such units that these units exert such an influence that they can consciously or unconsciously effect the price-levels of the farmer's produce. Again I am not a believer in nationalization as the solution, but I am a believer in regulation. The experience which I gained in the Food Administration on these problems during the War led to the feeling that I have expressed at that time, that such business should be confined to one line of activity just as we have had to confine our railways, banks, and insurance companies. Even this may not prove to be sufficient protection to free the market by free competition. If we have to go to regulation, however, it is my belief that it should be confined to over-swollen units and that the point of departure should not be the amount of capital employed, but the proportion of a given commodity that is controlled. The rates must depend upon the commodities in point. When such a concern obtains such size that it can influence prices or dominate public affairs either with deliberation or innocence, then it must be placed under regulation and restraint. I think our people have long since realized the advantage of large business operation in improving and cheapening the cost of manufacture and distribution, but when these operations have become so enlarged that they are able to dominate the community, it becomes of social necessity that they shall be made responsible to the community. The test that I would apply, therefore, is not the size of the institution or the volume of capital that it employs, but the proportion of the commodity that it controls in its operations. It is my belief that if this were made the datum-point for regulation, and if regulation were made of a rigorous order, this pressure would result in such business keeping below the limit of regulation. Thus the automatic result would be the building up of proper competition because men in manufacturing would rather conduct a small business free of governmental regulation than to enjoy large operations subject to governmental control. In other words, what we fundamentally want is to be free from domination of any artificial impediment in the free flow of commodities to the consumer.

The third point of attack at reduction in the cost of marketing is the most difficult of all. It lies in the fact that we have too many people engaged in distribution of food supplies. This is particularly the case in the retail end of distribution. There is one town in the United States that had one meat dealer to every 400 of population—and although their margins were very wide none of them made more than a bare living. The numbers engaged in distribution have naturally increased rapidly during war inflation and speculation such as we have gone through in the last five years. In such a period, much profit is earned by the simple process of marking up the price of goods on the shelf to the cost of replacements. I am not at all sure that we shall not find a great measure of remedy, both to the producer and the con-

sumer, now that the tide of inflation must soon turn, and there may be a process of marking down the prices of the goods on the shelf instead of marking them up.

In this connection, it is worth noting that, although agricultural products increased, yet the total commodity production of the United States has decreased by nearly 7 or 8% during the past 18 months. At the same time deposits in our credit banks have increased by nearly 20%. No one can defend this terrible increase of inflation since the Armistice. It is scarcely possible for a dealer in commodities to have escaped this magic wand of profits. If we have a wise and steady reduction in inflation, it will be a skillful dealer who escapes a reduction in the scale of profits. Whatever the result of this process may be to the distributor, it will reduce the margins between the producer and the consumer. It may also reduce the numbers of the persons engaged. Great wisdom will be required on the part of our Government in its great control of credit that this deflation shall take place progressively and with care, in order that there shall be no sudden breaks with their resulting demoralization, unemployment, and misery. One of the most effective measures in reduction of the cost of distribution has been co-operative distribution among producers. We have some successful marketing co-operations. They have proved their value both to the producer and the consumer. We have, however, never had the development of co-operation to the extent that European farmers have attained. To reach its best results, co-operation must grow on parallel lines by the consumers. As co-operative marketing does not reduce initiative or competition, I have never seen the bogie of Socialism in it.

There are other directions in which the costs of distribution can be constructively reduced on behalf of the farmer and consumer. For instance, many of our products are unstandardized; if they were standardized they could be sold by contract instead of by doubtful inspection on delivery.

We need an exhaustive economic and practical investigation into our great national boards of trades, with a view to extending their legitimate functions or preventing their abuse. The economic value to the farmer of having a daily national price created by the ebb and flow of absolutely untrammelled trade in central markets has never been fully appreciated. In commodities where such trading is wholly or partly unorganized, neither the farmer nor the consumer has any protection as to the determination of the right price and the margins between consumer and producer widen at once. Wider margins between producers and consumers is always a measure of hazard. When there is free and public market these hazards decrease. The abuses of exchange lie, of course, in the possibility of manipulation of their processes to create artificial prices for speculation. It is within the power of the speculators, and there is a tendency among them to eliminate these abuses. The War proved a great laboratory of experience in these matters, and the whole subject needs study and review.

Another field of interest in agriculture to engineers lies

in its mechanical equipment. Our American engineers have replaced manual labor by machines to a remarkable degree. This mechanical development has raised the whole economic and social status of our farmers to a point far above his European cousin. There is yet a great field of engineering for further assistance to the whole industry.

It is in all these directions that I believe lies the best field for restoration of balance between agriculture and industry. We want our industries to develop, but we want agriculture to keep pace. So long as we can feed our industrial population, the greater industry grows the greater is our whole community.

The organization and the processes of production and distribution are of centuries of development. This economic organism has come to have an extreme delicacy in its adjustment, in its response to stimulus, to effort, to the ability and character of all of the varied members of our community. Sudden disturbance and the introduction of 'isms' into this delicate organism can only bring us difficulties—can only reduce our productivity and tax our entire standard of living. We want to improve our machinery, we do not want to tear it down. Nor do we want it owned or run for the benefit of a few. The whole impulse to the maximum functioning of our productive machine lies in the self-interest of its members. It will never function on the basis of altruism. If we would have it function properly, we must promote that equality of opportunity which allows every member of this community to attain that position to which his abilities and character entitle him. To me, therefore, the test of the rightness of any measure is that it shall maintain and build up this equality of opportunity, that it shall preserve the initiative of the whole population. When we apply this test to governmental activities, I think we will find that it reaches its ideal more in negative than in positive action; that it should become positive only when the undertaking—such as a Panama Canal—is beyond the capacity of individuals or groups; that it receives its best exemplification in wise regulation against the shackling of the flow of competition, the advancement of understanding of the processes of production and distribution, stimulus to their improvement, the removal of impediments to its development, in creating in it all a pride of service to the community.

AMERICA leads the world in the tale and soapstone industry, not only in production but especially in manufacture and use. The output of tale in the United States sold in 1918, according to J. S. Diller, of the U. S. Geological Survey, was 191,477 tons, having an average value of \$10.91 per ton. This was a decrease of about 7000 tons in production as compared with that of 1917 but an increase of more than \$200,000 in value. Tale was not considered a war mineral and its production was retarded by the War, but the spread of knowledge concerning its uses and its usefulness has stimulated the industry, and a consistent increase in its application to many manufactures will be the result.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

OPERATIONS OF THE JEROME VERDE COMPANY

DUNCAN.—The \$150,000 mill of the Duncan Mining & Milling Co. has been completed and is now ready to operate as soon as the mine is unwatered and active stoping can commence.

DRAGOON.—A rich body of lead-silver ore has been

driven to cut the vein at the Gates Ajar mine has opened good ore 390 ft. in from the portal. The Potosi mine formerly the Bella Union has been taken over by Charles Schoenmehl and is now being developed. R. H. Humphrey is in charge of the work.

Work on the 650-ft. level of the Gold Ore continues to show an improvement in the ore originally found in the

HOISTING-ENGINES AT THE INSPIRATION MINE, MIAMI, ARIZONA

opened on the Texas-Arizona Mining Co.'s property now being operated by lessees. The force of men working is to be increased and shipments are to commence immediately.

KINGMAN.—It is announced that the Gold Road Annex company has been financed to the extent of \$50,000 for development. The tunnel being driven on the Marybell mine at Chloride has entered three feet of shipping ore. This property is the south extension of the old Payroll and is being worked by J. C. Rankine who promoted the Arizona Butte tunnel scheme. The tunnel that is being

recent strike. Assays are said to run as high as \$42 gold, 235 oz. silver, and 24% copper. Sinking to the 450-ft. level at the Tuckahoe mine has opened a new body of shipping ore. This strike together with lateral development has prompted the management to continue sinking to the 500-ft. level.

JEROME.—It is reported that the Jerome Combination drift on the 1080-ft. level has a six-foot face of mineralized schist carrying quartz. Three to four feet of the vein is said to be concentrating ore which runs 3 to 6% copper. H. P. Henderson, consulting engineer to the

Jerome Verde company, reports that during the last quarter of the year 611 ft. of drifting and cross-cutting was done and 115 ft. of winze was sunk; and that 1072 tons of ore assaying 10.29% copper, 0.09 oz. gold, and 1.43 oz. silver was produced. A winze has been sunk 100 ft. from the 1100-ft. level in the main top shear-zone and development work is being started on the 1200-ft. level to explore the downward extension of the vein opened on the 1100-ft. level. A cross-cut driven into the hanging wall from the main top-stope at the 780-ft. level recently cut a two-inch stringer assaying 17% copper. This stringer is being followed by a drift. A cross-cut is planned to be driven 50 ft. below the bottom of the 900 main top-stope in search of the downward extension of the ore.

PATAGONIA.—The Bland Mining Co. has recently opened a three-foot vein of lead and copper ore assaying \$50 to \$60 per ton in silver. The Bland mine will have its ore treated at the R. R. Mason custom mill. S. McGinley is manager. It is reported that a strike of rich silver-copper-lead ore has been made in the Blue Nose property at Patagonia. Tests are being made on the milling ore to determine the best method of treatment. Besides the milling ore there is a large tonnage of ore of shipping grade. The property is at present being worked by the Layman syndicate.

PHOENIX.—The directors of the United Arizona Mining & Milling Co. have been enjoined from issuing any additional stock as an outcome in the damage suit being brought by S. W. Badger against the company on the grounds that there is a breach of contract which granted him the sale of the company's stock.

COLORADO

POWDER MAGAZINE EXPLODES AT SMUGGLER UNION.

LEADVILLE.—The Leadville Leasing Corporation, a recently organized company headed by Albert R. Bailey, successful lessee at the Matchless mine, has taken over four mining properties on Idaho Park, Carbonate, and Breece hills and has commenced active work on the O'Donovan Rosa on Carbonate hill. Options on other properties have been secured and may be exercised by the corporation. Silver ore running as high as 1500 oz. was mined from the O'Donovan Rosa before water drove out the operators and the mine has been closed down since 1907. The Breece hill properties include the Peoria Boy and Hartford and the fourth property is the Rattling Jack. The Peoria, Hartford, and Rattling Jack may be operated through the Yak tunnel, already connected with the Peoria at the 1180-ft. level. All of the four mines are believed to have rich lead-silver orebodies. Ore running 140 oz. silver and 0.65 oz. gold is being developed on the Gertrude, in Colorado gulch, west of the city by J. Popovich and associates. The ore is coming from a vein at a depth of 115 ft. from the surface, and the first consignment of 22 tons, shipped without sorting, netted \$816. Three other cars since shipped are of a higher value.

CRIPPLE CREEK.—Stockholders of the Cresson Consoli-

dated Gold Mining & Milling Co. will be paid a dividend of 10 cents per share on March 10. With this payment the total sum paid shareholders will be \$8,491,162. Lessees of the United Gold Mines Co., which is controlled by the Golden Cycle M. & R. Co., have made a rich surface discovery on the Hardwood claim, Ironclad hill. From prospect holes not more than 15 ft. deep a 30-ton shipment has been made which brought settlement at the rate of \$80 per ton. Operations have been resumed, after temporary shut-downs of brief duration for repairs at the Dillon mine of the Granite Gold Mining Co., on Battle mountain and the Last Dollar mine of the Modoc Consolidated Mines Co. A Wellman-Seaver-Morgan electric hoist with capacity to 2000 ft. equipped with a 3-ton skip, has been ordered for the Last Dollar shaft. Both properties have resumed production.

TELLARIDE.—The favorable effects of the open winter are noticeable in the early speeding up of production. While January and the first half of February was a period of relative inactivity, the Tomboy and Smuggler companies are now getting out heavy tonnage, and still increasing their output. The Belmont Wagner Mining Co. continues steady production, but is not yet operating at full capacity. The Cinnaron, owned by John Wagner, is still down, due to lack of water-power. The Tomboy Gold Mines Co., Ltd., is now getting out two cars daily of lead concentrate, in addition to an occasional car of flotation-slime. A gasoline locomotive has been put into operation in order to facilitate the movement of ore from portions of the workings that are not yet electrified.

A peculiar explosion of a powder magazine in the upper level of the Humboldt mine, of the Smuggler Union company, resulted in the death of one man, the overcoming by powder fumes of two men, who recovered after medical attention, and the wrecking of the main shaft that connects the mine with the Sheridan adit. The shaft and the various levels were filled with debris, so that passage from the lower workings to the upper levels is not possible, and the mine will have to be re-opened from the Ouray side, a task attended with difficulty, as a force of men will have to make a trip over the treacherous snows between the Humboldt and the Mountain Top mines, and it is feared that the explosion may have started slides.

The cause of the explosion is not known. Theories advanced are a faulty electrical circuit, spontaneous combustion, or incendiarism. The powder magazine, storehouse, and air-compressor had been placed underground, with the approval of the State mine inspector, because of the nature of the surface, which is a very steep slope subject to frequent snow-slides. The magazine contained 17,000 lb. of explosives. Fortunately the air-compressor was out of condition, and the regular force of 25 men was not at work on this level or the casualties would probably have been more.

RICO.—Nutter & Co. are shipping from the upper workings of the Iron mine. The lower workings are under water. It is expected that the new tunnel-connection with the shaft will be made in the next few days. R.

S. Pellet & Co. have undertaken the operation of the Argentine group under a lease and bond from the Swickheimer estate. There is a great amount of development work to be done, as the shaft is caved in, and the lower workings will have to be unwatered, but when the property is re-opened, there will be a large reserve of broken ore that was too low grade to ship heretofore. It is believed that all of this ore can be marketed at a profit at the present price of metals. The Aetna M. & M. Co. has acquired a lease and bond on the Aetna D. B. & B. and the Honduras claims, and contracts have been let for the driving of a tunnel.

ORAY.—The Colorado-Zanett Co. is now shipping silver-copper ore from the Portland mine, operating in the lime formation. The Early Bird M. & M. Co. is now shipping ore. The mine is under lease and bond to A. E. McCormack of Ounray, and Geo. R. Gardner of Denver. Sylstra and Hutter continue to ship steadily from the Newsboy.

CREEDE.—Three distinct zones of silver ore are reported to exist directly under the town-site of Bachelor. The discovery was made by a prospector named Monkemeyer, who was led to investigate by the finding of petrified wood impregnated with mineral. A trial shipment brought returns of \$40 per ton.

MICHIGAN

CAR SHORTAGE.—LABOR SITUATION.

HOUGHTON.—There is only one thing that is curtailing the shipment of refined copper from the Lake Superior region at present. That is the inability of the railway companies to furnish cars. The production of every smelter is being forwarded to the domestic market with all the speed possible. Railways are trying to secure cars, but they cannot keep up to the large demand, which is unusual for this time of the year. Ordinarily the smelting plants in the Lake districts commence to accumulate copper in March against the opening of navigation. There is no expectation of any great increase in output for at least six months to come. The February product was small, but there should be improvement in March and April. There is a shortage of labor at the present time, and a considerable migration to manufacturing towns is expected in the spring, which will have a bearing on possible output.

Alhucac increased production in February. The output of 'rock' was 68,355 tons. This compares with 64,125 for January. It means that the production of copper for this mine will run over 1,600,000 lb. for February, which is a satisfactory showing for a short month. The Osceola Consolidated produced 49,000 tons for last month, a falling off from January when the output was 55,000 tons. Of this total 11,000 tons came from the old Osceola mine and the remainder from the Kearsarge.

Isle Royale continues to maintain tonnage of ore with an average content of more than 19 lb. of refined copper per ton. Four shafts now are producing. No. 1 shaft is getting out the smallest tonnage of any, 7,000 per month on the average; while the other three shafts, No. 4, 5, and

6 each more than double that amount. The grade of material now secured averages about the same in all three shafts and all are working at approximately the same depth. There is no present intention of resuming No. 2 or No. 7 shaft. The latter is the farthest south of all shafts but is not as deep as any of the others.

NEVADA

NEWS FROM DIVIDE. ASSESSMENT BY GOLDIFIED DEVELOPMENT CO.

DIVIDE. Reports coming from authentic sources indicate that George Wingfield is negotiating with New York

MAP OF CENTRAL COLORADO

men for the sale of his interest in the Tonopah Divide. It is said that sampling by engineers for the prospective purchasers has reduced considerably the estimated ore-reserves. Rumors of a merger of the Tonopah Divide,

Victory, Belchers, and other companies are persistent, but definite information cannot be secured on the subject. The first ore ever found in the "close-in" eastern part of the district has been opened in a cross-cut driven south-east on the 400-ft., or bottom level, of the Alto. This cross-cut is 300 ft. long, extending almost parallel to the line of the Arkansas claim of the Gold Zone. The ore was found in a vein striking north at the 200-ft. point and assays of \$26 were secured from a 1-ft. width in a 4-ft. vein. A drift is being driven to prospect this vein and at 130 ft. it will enter the intersection with an important vein striking north-east. A drift is being driven south to intersect the extension of the Garrey vein of the Tonopah Divide. Ore has been found in the High Divide, but details cannot be secured.

GOLDFIELD.—A cross-cut on the 300-ft. level of the Silver Pick has entered the Mohawk vein in a block leased from the Goldfield Development Co. The vein has a slight dip and only a small part on the foot-wall side has been exposed. The cross-cut entered the vein at a point 20 ft. north of, and 20 ft. beneath, where ore of shipping grade was found one month ago. The cross-cut will be continued to the hanging wall. The Florence Divide has relinquished the lease held by the company on the Florence and the block is being prospected by the Cracker Jack. Five miners, some former lessees in the Florence, have started repaving the No. 1 shaft of the Jumbo Extension, having secured a lease on a large block. They will work on the 600 and 800-ft. levels, which are in bad condition. A winze on the west-dipping shale has been sunk 50 ft. from the 815-ft. level of the Grandma. A raise has been driven 35 ft. from the 375-ft. level of the Great Bend to open the extension of orebodies found on the 236-ft. level. Ore of milling grade is exposed in the raise. The thirteenth annual report of the Goldfield Consolidated Mines Co., covering operations during 1919, states that the mill clean-up by the company in the early part of the year yielded \$124,672 and that a clean-up by a lessee which followed gave a net return of \$78,600, of which the company retained as royalty \$42,834. Mine and mill equipment amounting to \$24,492 was sold during the year and the estimated value of the equipment now on hand is \$105,012. In referring to the Development company, E. A. Julian, general manager for the Consolidated, says: "In the event that company definitely decides to proceed with plans now contemplated additional milling equipment will be installed by it sufficient to increase the capacity of the mill to 1500 tons per day." All of the equipment at Aurora, which was owned by the Consolidated company, has been sold with the exception of material valued at \$57,699, and since the report was issued arrangements have been made for the sale of the remainder. Cash in bank is \$284,540 and the surplus is \$898,100. The report states that "it is the opinion of the management that without question the loan to the Dolly Varden Mines Co. (\$172,292) will be paid in full during the early part of the coming year". The net realization from operations of the Goldfield Development Co. was \$70,727.

The Goldfield Development Co. has issued notice of assessment No. 1, at the rate of three cents per share, payable immediately and delinquent April 3. A statement of receipts and disbursements from February 1, 1919, to March 2, 1920, accompanying the notice of assessment, shows \$107,497 received from the sale of stock, \$36,000 from loans, and other receipts, principally from shipments of ore, making a total of \$278,516. Mining costs were \$71,790; construction and equipment, \$12,252; expense in selling stock, \$8543; storehouse expense, \$6018; pumping cost, \$7792; mill repairs, \$43,554. Total expenditures were \$276,901, and the balance on hand March 2 was \$1614. The report states that in November 1919 the mill was in condition to treat 600 tons of ore daily and that the mines could have been prepared for the production of a large tonnage by the expenditure of an additional \$20,000. To secure money to carry out the plans at that time the capital stock was increased 1,500,000 shares, only a small part of which the company has been able to sell "owing to adverse financial conditions". The report is signed by A. I. D'Arcy, general manager. Mr. D'Arcy recently stated that the mill would start treating 500 tons of ore daily on April 1. The report says: "We now plan to develop the high-grade milling ore exposed in the Florence and to watch development of the Silver Pick and Cracker Jack, and as soon as this development shows a sufficient tonnage of high-grade milling ore it is our intention to start the mill on a smaller tonnage of this higher-grade ore, and to gradually build up the tonnage and lower the grade to the point first contemplated in our large tonnage operations." The Cracker Jack is a company distinct from the Development which holds a lease on the Florence. In referring to the rich ore recently reported by Mr. D'Arcy to have been found in various parts of the mines, he says: "None of these exposures have produced an appreciable tonnage." The maximum tonnage it is planned to treat in the mill is given as 1500, instead of 2000 as in previous statements.

COPPER MOUNTAIN.—Plans for further work by the Jumbo-Copper Mountain, controlled by stockholders of the Jumbo Extension of Goldfield, definitely have been abandoned. The company plans to take over a prospect in another district and raise funds for development through an assessment.

SILVER PEAK.—The Silver Peak Chemical Co. has bought a group of 10 claims adjoining the original holdings 9 miles north-east of Silver Peak. The company is building a leaching-plant to treat what is said to be the only known deposit of water-soluble potash alum.

OREGON

REPORTED DISCOVERY OF PLATINUM IN SIXES RIVER DISTRICT.

GOLD HILL.—The placer miners of south-west Oregon are feeling blue just now because the dry weather and the lack of snow in the mountains has lowered the water in the streams to such an extent that all placer mining is coming to a standstill.

CURRY CO. NTY.—Platinum ore, according to report,

has been uncovered along the Sixes river in the western part of the county. The deposits have been traced for nearly twenty miles in a north-easterly direction, ending near the mouth of the Sixes river, and some of the assays run as high as 18 oz. per ton. Many claims are being staked along the line of discovery by locators from Marshallfield and Bandon. Mining men of the region doubt the character of the find, although platinum ore was found in the Highland gold-quartz mine in the Gold Hill district in Jackson county as early as 1916.

Placer mining has been carried on for more than thirty years in this district, and in later years lead to considerable activity in quartz mining and the recovery of platinum from hydraulic placer operations. The country rock of the district is predominantly shale, sandstone, and conglomerate of the Dothan and Myrtle formations, with frequent intrusions of basic igneous rocks, which are altered in numerous places to serpentine. A considerable area of greenstone is found in the headwaters of the Sixes river near Rusty butte in the Salmon mountains and an area of basalt is found in the north-central part of the district. Wagon-roads are confined to regions near the coast and trails are the only means of transportation in the main part of the district.

UTAH

ZINC-OXIDE PLANT AT SALT LAKE CITY.

SALT LAKE CITY.—Construction of a zinc-oxide plant by the Utah Zinc Co. has been started. The plant will be situated five miles south of Salt Lake City. It is estimated that the first unit will cost \$150,000, and the capacity will be 40 tons per day. The Wetherell process will be used. The product of the plant, which will treat only oxidized zinc ores, will be a high-grade zinc oxide, much used in the making of automobile tires, as it gives rubber the power to withstand weathering agencies. Zinc oxide is also used in paints as a filler. The main supply of ore for the plant will come from the Tecoma mine, $2\frac{1}{2}$ miles south of Tecoma, Utah, on the Southern Pacific railroad. The new plant is expected to be in operation by June 1. The directors of the company are: L. B. McCormick, Melvin H. Sowles, Herbert Salinger, L. D. Forman, and James W. Wade.

At the meeting of the board of directors of the Utah Copper Co. in New York City on February 25, a dividend of \$1.50 per share was declared, payable March 31. This will call for a total payment of \$2,436,735. During 1919 the company paid its stockholders a total of \$6 per share.

EUREKA.—The Ridge & Valley Mining Co. had an output of 6447 tons of ore during 1919, from which was produced 105,011 oz. of silver and 2,044,280 lb. of lead. The gross proceeds amounted to \$181,602, while total expenses were \$167,024, leaving net proceeds for the year of \$14,578. The Gemini Mining Co., another of the McChrystal properties, mined 7804 tons, from which was produced 143,983 oz. of silver and 1,499,820 lb. of lead. The gross proceeds were \$201,577, while total expenses were \$222,538, leaving a deficit of \$20,962.

Eighteen mines in this district shipped 149 earloads of

ore during the week ending February 27, as compared with 138 cars the previous week. The Chief Consolidated shipped 33 cars; Tintie Standard, 25; Iron Blossom, 15; Centennial Eureka, 15; Dragon Consolidated, 10; Eagle and Blue Bell, 10; Colorado, 7; Grand Central, 7; Gemini, 5; Victoria, 5; Mammoth, 1; Ridge and Valley, 3; Swansea, 3; Martha Washington, 2; Bullion Beck, 2; Eureka Hill, 2; Empire Mines, 1; and Sunbeam, 1.

It is understood the Tintie Standard company is considering the erection of a milling plant. Some time ago it was announced that the company had secured a large tract of land and water rights near Warm creek. The company is now building a switch from the main Tintie

MAP OF UTAH

line of the Rio Grande railroad to this mill-site. It is anticipated that the construction of the spur track will be completed within the next two weeks at which time the equipment for the mill buildings will be delivered and construction started. The machinery for the mill has been ordered and it is hoped to have the plant in running order before the summer is far advanced. Conditions throughout the Tintie Standard mine are reported to be satisfactory and the present output amounts to about three earloads per day.

AMERICAN FORK.—The Treasure Hill Mining Co. in American Fork canyon has more than 300 tons of high-grade ore piled on the dump awaiting the coming of spring when shipments can be started. Operations at the present time are being carried on through the upper tun-

nel of the Silver Dipper property. The Treasure Hill Co. has taken over the Emma group, the Silver Dipper, Daniels group and Bredermeyer group, in addition to having a right of way through the Non-compromise claim owned by the Holden interests.

BIGHAM.—At a meeting held by the striking miners in Canyon hall on the afternoon of February 29, a vote was taken to declare the strike off. Albert Wills, State organizer of the I. W. W., chairman of the meeting, could not stem the tide in favor of going back to work. It was estimated previous to the meeting that all but 100 of the miners who obeyed the strike summons had either returned to work or sought employment in other camps. Many of the miners took up their tools following the mass meeting held recently in the Commercial club, at which it was voted to appoint a committee from the workers to meet with the operators.

PARK CITY.—On the 1800-ft. level of the Ontario mine, the lowest working level at the present time, ore is being followed both east and west, according to Newton Dunyon, superintendent. At the start the ore, which averages 50 oz. in silver and from 10 to 12% lead, was found in the bottom of the drift. For the last 100 ft. the ore has bedded out from the fissure for a distance of from 20 to 25 ft., with a thickness of 3 ft. The shaft to the 2000-ft. level and the drift on this level have been unwatered. After cleaning up this drift, development work will be immediately undertaken. An orebody of good size has been opened up by No. 7 and No. 8 raises from the 1700-ft. level. No. 8 raise, from a point approximately 30 ft. from the 1700-ft. level to the 1500-ft. level, has been continuously in ore. No. 7 raise, about 150 ft. west of No. 8 on the same fissure, encountered the orebody about 30 ft. above the 1700-ft. level.

At the annual stockholders' meeting of the Silver King Consolidated Mining Co. of Utah, which was held February 28, the following board of directors was elected: Solon Spiro, William Pischell, Herman Harms, D. L. Wertheimer, Richard P. Morris, Sherman Fargo, and Harry A. Lee. Despite the fact that two months time was lost during 1919, because of the labor strike in the district, the tunnel being driven by the company was advanced a total of 2622 ft. The face of the tunnel on January 1, 1920, was 11,623 ft. from the portal and is now reported to be 12,200 feet.

Ore shipments from the mines of the district for the week ending February 27 totaled 2400 tons as compared with 2264 tons for the previous week. Ontario shipped 714 tons; Judge Smelting, 648 tons; Silver King Coalition, 492 tons; Daly-West, 230 tons; Naildriver, 165 tons; and Daly, 52 tons.

MILFORD.—According to J. G. Scott, general manager of the Monitor mines, located near here, an important strike was recently made in the lower adit at an approximate distance of 118 ft. from the portal. The ore, so far as present developments indicate, contains silver and lead, with considerable iron. It is thought that this is a continuation of a streak which, in the workings 225 ft. above, assayed 30 oz. silver, 46% lead, and 1% copper.

WISCONSIN

NUMEROUS NEW PROPERTIES ARE BEING OPENED ON THE ZINC-RANGES.

LIVINGSTON.—The New Jersey Zinc Co., operating mines on the Coker zinc-range, has recently developed three mines designated as Coker, No. 1, 2, and 3. A new shaft is in ore on No. 2, and a new power-plant is nearing completion at No. 3. In addition new homes for employees have been constructed. No. 3 is on the old Sunset property and is a continuation of the same ore-range that extends through the other properties. Miners declare there is more zinc ore in sight now than ever before in all the forty years these lands have been mined.

Stockholders of the M. & A. Mining Co., operating the Big Tom mine, at a special meeting held at Platteville recently, voted to resume operations after a shut-down lasting more than a year. A new reservoir is being constructed while the mine is being unwatered and minor repairs and renewals are being made to the mill equipment. It is believed the plant and mine will again be at work by March 15. The Big Tom was a heavy producer of low-grade ore and was shut-down after the War on account of low prices for zinc concentrate.

The B. M. & B. Mining Co., operating the Squirrel mine, has driven to connect with new discoveries determined by drilling, and ore production is again under way. Estimates place the yield at from 30 to 40 tons of high-grade zinc concentrate per day. The Biddick mine, another low-grade producer in this district, is ready to resume output after a long shut-down due to low prices for ore. The Vinegar Hill Zinc Co. has two mills in operation and is making from 1000 to 1200 tons of zinc ore monthly. This product is delivered to the National Zinc Ore Separators, at Cuba City, for electro-magnetic separation.

MINERAL POINT.—The oxide-furnaces of the Mineral Point Zinc Co., four blocks of 12 double compartments, are again operating after a year or more during which but two blocks were kept hot. The working force has been largely increased. Private warehouses, in addition to the company's own, have been emptied by recent shipments.

PLATTEVILLE.—The Block-House Mining Co., after a shut-down lasting nearly a year, has decided to resume production of zinc ore. A new power-plant and derrick have been completed 1000 ft. east of the mill and a new shaft is bottomed in ore. A surface-tramway connects mine and mill. On the Goke farm ore has been proved with drills, and construction work on a new 150-ton zinc-mill has been begun, which when complete will give the Block-House two active plants. The ore has been proved ahead of the Goke tract and should market conditions warrant, a third mill will be built. The owners of this mine declare they have ore to last thirty years blocked out. Two magnetic-separating plants are treating product piled up in bins prior to the shut-down. Employment will be given to a hundred employees including mill men.

MILLBURN.—The Graham mine, one of the producers in this field operated by the Vinegar Hill Zinc Co., is ship-

ping steadily. Drills are at work proving the Ginty farm south of the Graham and future developments are contingent on what is developed on this tract. Discovery of zinc ore in quantity will warrant the removal of the Graham equipment to the new field as the Graham mine it is officially declared has about been exhausted.

GALENA.—The New Jersey Zinc Co., owner in fee of the Marsden lands on which the Black-Jack mine is situated, has in this property an exceptionally consistent producer. The land was first mined for lead in 1854. In 1877 it was taken over by the Illinois Zinc Co., and was known as the Peru mine. It was abandoned in 1883. Records show at times as many as 150 miners employed and shipments of zinc ore amounting to 400 tons monthly.

important to our mining industry that all possible knowledge of British Columbia geology shall be made available.

And be it further Resolved, That this Legislative Assembly of the Province of British Columbia does strongly urge the Dominion Government:

(1. To take some immediate action to prevent further depletion of this most valuable branch of the Civil Service; (2. To offer adequate inducements to engineering and scientific students of Canadian universities to undertake training with a view to employment on the Geological Survey of Canada, in order to provide trained men for the future.

STEWART.—The Portland Canal Tunnel property, on Glacier creek, a tributary of Bear river, is to be re-

AN ELECTRIC ORE-TRAIN AT GRAND FORKS, BRITISH COLUMBIA

The mine was purchased by the New Jersey Zinc Co. from the Black-Jack Mining Co., organized in 1906 and operated by this corporation until 1908. The mine sold for \$360,000.

BRITISH COLUMBIA

RESIGNATIONS OF GEOLOGISTS.—NEWS FROM PORTLAND CANAL REGION.

VICTORIA.—Resignations of members of the Geological Survey of Canada have developed a serious situation insofar as the Province of British Columbia is concerned, because some of those who have been engaged in geological work in the Province for years have left the service without completing important work. Wm. Sloan, Minister of Mines, has given notice of his intention to move a resolution from which the following is abstracted:

Be it Resolved, That this Legislative Assembly of the Province of British Columbia expresses its appreciation of the great value of the work of the Geological Survey of Canada as assisting the mineral development of this Province, and views with apprehension the depletion of the survey staff, especially at this time, when, with the world entering upon a period of reconstruction, it is most

opened. In the 'boom' of 1910 a tunnel was driven for a considerable distance into the mountain and several ore-bodies were cut, but were not explored to any extent. It is proposed to continue the tunnel and to drive on the ore-bodies. The Anglo-Belgian Syndicate, a Belgian corporation capitalized at \$50,000,000 with offices in New York, San Francisco, and Montreal, has added the Independence and Independent groups to the already large number of properties it has under option. W. A. Meloche, representative of the syndicate, arrived at Stewart on February 19, bringing with him 200 tons of supplies. The syndicate will start operations on the Northern Light, Cobalt, and Woodbine groups, which adjoin the Premier property to the north and west, and on the Spider group, on which unusually rich ore was uncovered last fall by surface-stripping and open-cutting. The Citizens Association has posted notices on the wharf, stating that no orientals are desired in the camp. The recent labor strike at the Premier mine is said to have been caused by the employment of a Chinese cook at the boarding-house. A transportation agent is responsible for the statement that more than 700 passengers are booked from Europe directly to Stewart. It is stated that

the Grand Trunk Pacific company will put larger boats on the route as soon as the wharf has been repaired. Seattle interests have purchased the Empress hotel, and will remodel and furnish it. The hotel, which has 80 bedrooms, was erected during the previous boom. The face of the cross-cut at the New Alaska is in good ore. The faces of both tunnels at the Forty-Nine are in ore. Operations have been suspended at the Mineral Hill group, pending re-organization of the operating company. The property is to be taken over by the Mineral Hill, Ltd., of which J. W. Stewart is president.

PRINCE RUPERT.—Good progress is being made with the new tunnel at the Silver Standard mine, near Hazelton, and it is expected that the main vein will be cut by the end of March. Several stringers of rich ore have been cut. The mill has been closed temporarily for a thorough overhauling, and it is possible that a flotation plant will be added. The mill treats about 25 tons of ore per day, the crusher and jigs being run for 8 and the tables for 16 hours, but the extraction is low and the concentrates produced contain about 35% zinc and 35% lead, respectively. Both concentrates are rich in silver. The Golden Crown group, near Usk, is being developed by the Kleanza Co. The vein, which contains gold, silver, and copper, is said to have been traced by open-cuts for three miles. Diamond-drilling will be started in the spring. The Taltarnip Mining Co. is developing a 4½-ft. vein on the Silver Fox group, which assays up to \$800 per ton. The property is situated on Anderson creek.

NOVA SCOTIA

A NEW STEEL-PLATE PLANT.

SYDNEY.—A notable advance in Canadian metallurgical industry is marked by the opening of the new steel-plate mill of the Dominion Steel Corporation, which is now in steady operation. The output has been tested and found fully equal to the requirements of Lloyd's. The mill, which was erected at a cost of approximately \$5,000,000, was built under an agreement with the Canadian government, which, to ensure a market for the output, contracted to take 50,000 tons of ship-plates per year for a term of five years at \$3.65 per 100 lb. The total capacity of the plant is given as 12,000 tons of ship-plate per month, but other varieties of plates will be turned out. The enterprise has been established at an opportune time, as the iron and steel industries are at present badly handicapped by the shortage of the supply of steel from the American mills. The plates made for the Government are shipped to the Halifax shipyards.

ONTARIO

PORCUPINE NEWS.—PLAN TO BENEFIT RETURNED SOLDIERS.

PORCUPINE.—As was anticipated the option held by the Dome Mines on the Dome Extension property, which expires March 15, has been extended to September 15. A report of operations on the Dome Extension states that up to the end of November about \$30,000 had been expended in exploration and opening up the orebodies. On the 600-ft. level an elliptical orebody of about 14,000 sq.

ft. in area had been developed, samples from which averaged \$4.62 per ton. However, 267 ft. of channel sampling in the better part of the deposit gave an average assay of \$5.37, and 4878 tons of ore had been sent to the mill having an average grade of \$4.39. Work under the option had been greatly retarded by shortage of labor and water in the workings in excess of the capacity of the pumping plant. The main shaft of the Clifton-Porcupine has been put down 225 ft. and a station cut at the 200-ft. level where preparations are completed for lateral work. Cross-cutting is being started to open up veins which yielded satisfactory results on the 100-ft. level.

KIRKLAND LAKE.—During January the Lake Shore made a new high record treating 1765 tons of ore with a production of \$45,428, being an average recovery of \$25.80 per ton. The Tough Oakes is not expected to resume operations for at least another month, as H. H. Johnson, the general manager, is still absent in South Africa and may not return for some weeks. The proposed merger of the company with the Burnside, Aladdin, and Sylvanite is making slow progress. It is understood that the English companies owning the Aladdin and Burnside have gone into liquidation as a preparatory step to the merger, but it is regarded as doubtful whether the Sylvanite will be included in the amalgamation. At the Bidgood a mining plant, including a compressor with three drills, is being completed. The shaft will be put down to 100 ft. and a level run for drifting on the vein which has a width of 8 ft. A cross-cut will be driven to cut a vein that outcropped over a width of 25 ft. on the surface.

COBALT.—The Keeley mine, in South Lorrain, after lying idle for a number of years was re-opened on March 9. The operating company, the Associated Gold Mines, Ltd., of Western Australia, announces that a 20-stamp mill will be erected this year. This will eliminate the former heavy expenditure for transporting the ore by truck and steamer to the railway. The Buffalo Mines has gone into voluntary liquidation, a winding-up order having just been made. March 13 is the date set for creditors to record their accounts.

Another shoot of high-grade ore has been discovered in the Temiskaming mine. Somewhat similar shoots were opened up during the past year, but they were comparatively limited in extent. For that reason, the management makes no attempt to estimate the importance of the present find before carrying on more work.

The Cobalt branch of the G. W. V. A. is urging the Ontario government to grant all returned soldiers who were bona fide prospectors prior to enlistment, three free mining claims of 40 acres each. It is estimated that about 10,000 men would come under the grant. This would involve the surrender of about 30,000 claims or approximately 1,200,000 acres, and would comprise an area equal in extent to 52 townships of the size of Tisdale township in which are located the producing mines of Porcupine. It is not thought that the Government will accede to the request, but may suggest other benefits for the returned prospectors.

ARIZONA

Wickenburg.—The Abe Lincoln Copper Co. is building a 100-ton flotation plant, some of the equipment having already arrived at Wickenburg. The equipment which includes ball-mills, tables, flotation machines of the new oscillating-cell type, and an Oliver filter, will be operated by gasoline engines. Walter N. Burke is consulting engineer for the company and is supervising the construction work.

CALIFORNIA

Amador County.—Extensive damage is feared as a result of a fire raging in the Kennedy mine. The presence of gas recently directed attention to the possibility that the workings were afire. The blaze first was discovered at the 3330-ft. level. All operations in the mine have been suspended, 140 miners being laid off until the fire is extinguished. The fire is believed to have spread into the Kennedy mine from the workings of the Argonaut mine, which is an adjoining property. The underground workings of the two mines communicate.

Both mines have been productive gold yielders and among the deepest gold mines in the United States.

Bishop.—The Sam Piper mine has passed under bond and lease to L. L. Mushett of Tonopah. This property produced silver-lead ore in 1870, and was worked in a small way for several years prior to 1890. A three-foot vein of silver ore has been found. Mushett and associates have also acquired claims at Lincoln and arranged for a carload shipment.

Forbestown.—James H. Kendall, of Berkeley, has acquired the Denver mine, in this district, and the Beehive at Woodleaf. A large tonnage of mill ore is exposed and the erection of a 30-ton Gibson mill is to start at once. More units will be added if conditions warrant. The Beehive workings are being cleaned out preliminary to opening of new ground.

Forest Hill.—A ball-mill and flotation plant has been completed at Snow Bird, and ore is going steadily to the mill. Mine developments are proceeding with satisfactory results. The Snow Bird was operated several years ago by John De Lorsi, but is now owned by George McCall and Edward Lewis. Driving of the cross-cut tunnel on the Georgia Hill group is progressing with the purpose of cutting the ore at a point 1500 ft. from the portal. Prospecting at Spanish Ledge has exposed promising ore. New equipment has been received.

COLORADO

Mayday.—Avery and Brandiger, lessees on the Idaho, are shipping about two cars per month from a 3-ft. vein assaying 2½ oz. gold with some silver. The Jumbo Mining Co. is shipping a car per week from the La Plata mine which is said to carry 14 oz. per ton in silver. Paul Dalpra has secured a lease on a block of the Jumbo and has sent out 200 sacks of ore which is reported to run 23 oz. per ton in silver. John Graves is driving a 600-ft. cross-cut at the Graves to explore a 14-ft. vein assaying 0.20 oz. gold and 3 oz. silver. The breast of the cross-cut, which is in 400 ft., shows an 8-in. streak of quartz assaying 0.60 oz. gold and

4 oz. silver. Shipments made from this property have assayed from \$14 to \$200 per ton.

IDAHO

Coeur d'Alene. Development work has been resumed on the property of the Iron King Mining & Milling Co. The mine is situated a few miles west of Wallace and the work is in charge of A. P. Reinsardt. About 3000 ft. of development work has been done on the property, but for the last few years it has been idle. The Paragon Consolidated Mining Co., controlled by St. Paul capital, has purchased from Spokane interests all of the holdings of the Murray Hill Mining Co., situated on Paragon gulch, 5½ miles east of Murray, for a reported consideration of \$100,000 cash.

Hailey.—What promises to be an exceedingly rich body of ore has been discovered in the Lark claims 2½ miles southwest of Bellevue. The find was made by Werry brothers and Schaufelberger, and consists of 4½ ft. of galena ore containing 70% lead and 250 oz. of silver per ton.

Lakeview.—Reports indicate that an active season is to be expected in that district. The principal properties of the district are the Webber, Keep Cool, Conjecture, Rainbow, and Venezuela. The only one operating now is the Conjecture. The Webber and Rainbow groups were recently examined by an engineer representing British Columbia capitalists and it is understood that negotiations are now in progress for the sale of these two.

MISSOURI

Joplin.—The Waco Mining Co. expects to start its No. 3 mill by March 15 and to continue steady operation thereafter. The plant is one of the best built and equipped of any in the tri-State district. It is of 1000 tons capacity per shift and up to date in every respect. Before starting to erect the mill the company carried out extensive drilling, proving an orebody that will provide continuous operation of the mill for several years.

The Mine LaMotte, one of the famous lead mines of south-east Missouri, is the subject of a controversy in court, in which action has been started to bring about proceedings to foreclose the \$1,000,000 mortgage against the property, which has been in the hands of a receiver for several years, and to terminate the receivership.

MONTANA

Butte.—The Anaconda company is cutting a station on the 1000-ft. level of the Orphan Girl property. It is expected that cross-cutting to the Anglo-Saxon vein will be started. The vein was opened on the 500-ft. level, where it is said to have a width of 30 ft. and to contain silver ore assaying about 14 oz. per ton.

A shortage of miners is reported to be preventing the operation of the mines upon as large a scale as was planned when a number of shafts were re-opened in January. The Bell & Diamond and Silver Bow mines of the Anaconda company have curtailed operations. Even with the two shafts closed, the lack of a sufficient number of miners is acutely felt. All available men are at work and from 600 to 700 would be employed if they could be found, according to W. B. Daly, assistant general manager of mines.

UTAH

Alta.—Recently the Big Cottonwood Coalition Mines Co. bought a controlling interest in the Copper King Mining Co., which owns eight full claims adjoining the property of the former. This gives the Coalition company the apex on all the important fissures which traverse the property, according to C. E. Robertson, secretary and treasurer. Development work has been carried on all winter and is being steadily pursued. Since the company began operations on June 1, 1919, the face of the main adit, which is being driven to cut the Prince of Wales fissure at a vertical depth of 1000 ft., has been advanced a distance of 550 ft., until now the tunnel has a total length of 2575 feet.

WASHINGTON

Seattle.—Mining men from several Western States, Alaska, and British Columbia are expected to attend the Seattle sessions of the International Mining conventions to be held April 7 to 10. Henry Landes, head of the mining department of the University of Washington, who is chairman of the program committee, expects 1500 to attend.

Invitations to speak at the convention have been sent to Herbert Hoover, president of the American Institute of Mining Engineers; Horace Winchell, past president of the Institute; T. A. Rickard, editor of the 'Mining and Scientific Press'; and George Otis Smith, head of the United States Geological Survey.

Moving picture stories of the coal, petroleum, and copper producing industries are to be exhibited at the convention. Round-table conferences will be held.

Obituary

Hennen Jennings died on March 5 at Washington after a long illness. He was born at Hawesville, Kentucky, in 1854 and graduated from the Lawrence Scientific School at Harvard in 1877. After graduation he came to California and became associated with Hamilton Smith, H. C. Perkins, and Ross E. Browne. He was engineer successively at the North Bloomfield and New Almaden mines in California. In 1886 he married the daughter of John C. Coleman, one of the two brothers that owned the Idaho mine at Grass Valley. A year later he went to Venezuela as manager of the El Callao mine, remaining there two years. In 1889 he went to the Rand, as engineer to Jules Porges & Co., the predecessors of Wernher, Beit & Co. He became consulting engineer to the firm, retaining this important position until his retirement in 1905, spending the last seven years in London, where he was a recognized leader of the profession. In 1903 he was elected president of the Institution of Mining and Metallurgy; in 1904 he was re-elected and also received the gold medal of the Institution in recognition of his efforts in behalf of technical education. On his return to the United States in 1905 he settled at Washington and served as consulting engineer to the Conrey Placer Co. in Montana, an enterprise in which, through a bequest, Harvard had acquired a large financial interest. In later years he was consulting mining engineer to the U. S. Bureau of Mines and in 1918 he undertook an investigation of the gold-mining industry. His career was long, useful, and full of honor. A man of keen public spirit, he took a leading part in the efforts to promote technical education in South Africa, England, and the United States; he gave his help to the betterment of the profession and to the welfare of all those engaged in mining. A man of cautious, rather than of brilliant, mind, he proved a rarely sagacious adviser to the financial house identified with the biggest operations known to the modern world and steered it safely through periods of dangerously speculative excitement. He was loved by many and respected by all. To his son he leaves an honorable tradition and to his friends a happy memory. T. A. R.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. J. Loring is in New York.

T. J. Jones is at San Mateo, California.

Herbert J. Daly is in Western Australia.

Joseph Errington, of Oakland, has gone to Vancouver.

R. H. Stretch has returned to Seattle from southern California.

Frank R. Wicks has opened an office as consulting engineer at 1006 South Hill St., Los Angeles.

James G. Parmelee, formerly at Salt Lake City, is now with the Harding Company in New York.

Jay A. Carpenter, formerly at Tonopah, has established himself at 1006 South Hill St., Los Angeles.

J. T. Smoot, former petroleum chemist of the U. S. Bureau of Mines, is spending a few days in San Francisco.

Loftus Hills has been appointed Government Geologist of Tasmania, in succession to the late **W. H. Twelvrees**.

C. D. Kaeding, general manager for the Dome Mines company, at Porcupine, Ontario, was here during the week.

Walter N. Burke has been appointed consulting engineer to the Abe Lincoln Copper Co. at Wickenburg, Arizona.

Leslie V. Waterhouse has resigned as mill-superintendent to the Mount Lyell company, and is now residing at Sydney, N. S. W.

E. J. Hoorwood, manager for the Broken Hill Proprietary Co., has been transferred to the Melbourne office of the company.

Forest Rutherford, consulting metallurgist, has returned to New York after making an extended trip through the South-West.

D. A. Lyon, supervisor of stations, U. S. Bureau of Mines, spent two weeks during February in San Francisco and Los Angeles.

G. M. Colvocoresses, general manager for the Consolidated Arizona Smelting Co., at Humboldt, was in San Francisco for a few days.

E. C. Andrews has been appointed Government Geologist to the Mines Department of New South Wales, in succession to **J. E. Carne**, retired.

Charles E. Mills, formerly general manager for the Inspiration Consolidated Copper Co., at Miami, was in San Francisco, on his return from New York.

Arthur L. Walker, Professor of Metallurgy in Columbia University, will deliver a course of lectures on the non-ferrous metals at Harvard University during this term.

R. E. Colhom, petroleum technologist of the U. S. Bureau of Mines, has changed his headquarters from San Francisco to Dallas, Texas, where he will be in charge of the Bureau's office.

A. E. Strick, superintendent of the Mount Elliott copper mine, in Queensland, arrived on the 'Sonoma' from Australia on his way to a visit to the principal copper mines of this country.

Frank H. Sistermans, mining engineer of New York, has left for Mexico, where he will examine various mining properties in the interest of Eastern clients. His address will be care of Apartado 733, Mexico City.

Edwin S. Berry, of the firm of Yeatman & Berry, New York, arrived in San Francisco on March 7 from Australia, where he has been advising the Mount Elliott company in the Cloncurry district, of Queensland.

P. B. McDonald, assistant professor of English in the College of Engineering of New York University, has been engaged by the Western Electric Co. to give a series of 24 evening talks to engineers on the use of English.

Zinc dust, cents per pound.....	

EASTERN METAL MARKET

(By wire from New York)

March 8—Copper is dull and weak. Lead is active and higher. Zinc is quiet and lower.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46 65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

There is a difference in banking circles as to whether the Federal Reserve Board should suspend reserve requirements of the Federal Reserve banks against net deposits at this time. On the whole, the consensus of opinion is that the occasion does not call for such action by the Board.

In the first place, to do so might create unwarranted apprehension in the money market. Many people would not understand the reasons, and might magnify the emergency. On the other hand, such action would tend to nullify, to some extent, the measures now being put under way by the Federal Reserve authorities to bring about contraction. The Federal Reserve banks and their discount rates are the instruments by which the Reserve Board proposes to bring about deflation. If permission is given to reserve banks to go below their reserve requirements, they will not be able to exercise the same restraining influence upon credits.

The situation, in short, resolves itself into this: Either the Federal Reserve Board must suspend reserve requirements, as it is permitted to do, for certain periods; or else, if deficiency in reserves continues, the Reserve banks must raise discount rates still higher. Bankers are of the opinion that the Reserve Board would rather have recourse to the latter step, under the circumstances, than allow the Federal Reserve banks to continue any length of time below their deposit reserve requirements.

Able and successful bankers, however, believe that the Federal Reserve law should be amended in many particulars, notably in the case of deposit requirements. They say that while the 10% gold reserve should be retained against the notes, it is impracticable to have a hard and fast rule in regard to reserves against deposits. Reserves are made to be used, and this is just such an occasion when they should be.

As the loss of gold through exports, concurrently with expanding credits, is the cause for depreciation in reserves at the Federal Reserve bank, the question was put to a number of leading bankers whether an embargo should not be placed upon gold exports at present. In most cases bankers replied that gold exports should not be restricted, notwithstanding that the United States is now the only real free gold market in the world. Europe is sitting tight in its gold holdings, in spite of the heavy balance against her in favor of this country, while we are shipping gold in payment of such debts as we owe in the Orient and South America. Bankers say that this is now the test of our claim as a free gold market and our ability to play the role of international banker. It is recalled that we imported from Europe over \$1,000,000,000 in gold in the early stages of the War, and we should not be reluctant to part with some of this gold gain now.

One banker suggested, however, that the Federal Reserve Board might issue regulations whereby gold should be taken for export only on affidavit by the shipper that it is for the purpose of settling a bona fide debt. In other words, the practice of shipping gold by banking houses as a profitable exchange operation should be prohibited. This might be accomplished less effectively through a Government order than by a moral agreement among the banks. It is believed their support could be enlisted by the Reserve Board in order to conserve the United States gold supply for the general benefit of business.

Foreign quotations on March 9 are as follows:

Sterling, dollar:	Cable	3.66
	Demand	3.65
Francs, cents:	Cable	7.38
	Demand	7.37
Lire, cents:	Demand	5.62
Mark, cents:	Demand	1.50

Eastern Metal Market

New York, March 3.

All the markets but that of lead are quiet and lower and demand is light.

Copper demand could hardly be lighter than just now and all sellers have reduced their asking quotations.

The tin market is exceedingly quiet with consumers practically uninterested. Values follow the highly speculative changes in London, which are very erratic.

Supplies of lead for nearby delivery are scant and values are advancing because of considerable demand.

Inquiry for and buying of zinc has lessened and quotations have declined also.

Demand for antimony is good but supplies are not plentiful. Prices are higher.

IRON AND STEEL

While buying for the railroads did not wait for their return to their owners on March 1, the steel trade has been busy in the past three days with new calculations of tonnage that will come to the mills in the next two months for railroad account. Estimates of early car contracts have gone as high as 100,000. The favorable decision in the Steel Corporation suit, though received with much satisfaction, has not been a market factor. The buying of finished steel by the railroads for car repairs and other purposes will be considerable. The Pennsylvania took about 10,000 tons of plates, shapes, and bars last week. Opposing views are coming out on probable developments in the next three months. It is known that some independent mills have no large bookings ahead, but much hinges on the rate at which transportation can be improved. There is questioning of the high prices established for certain products; at the same time, the rigid attitude of sellers remains.

Pig-iron production last month was at the highest rate since February 1919. The total for the 29 days was 2,978,879 tons, or 102,726 tons per day, as against 3,015,181 tons in January, or 97,264 tons per day. In 1919 the February output was 105,006 tons per day.

COPPER

Practically all large producers have revised their estimates of values and lowered their quotations to 18.75c., New York, for electrolytic for early delivery. Lake producers are practically on the same level as to prices. These quotations are largely nominal for there is practically no demand and the market could hardly be any duller. A buying movement is expected in the next two or three weeks or some time in March for the last movement of this nature in December supplied most consumers only for first quarter, although some of the buying included second quarter delivery. That a brisk foreign demand is inevitable ere long is firmly believed though at present it is negligible.

TIN

The market has been very quiet and devoid of much business. Consumers have bought but little and most of the trading has been among dealers. At present consumers are practically out of the market and trading between dealers has lessened. Spot Straits tin fell to 61c., New York, on February 27 but has risen again to 63.25c., New York, which was the quotation yesterday. These fluctuations have been almost entirely governed by the changes in the higher speculative London market, when spot Straits fell from £418 per ton a week ago yesterday to around £403 and then went back yesterday to £411 per ton. Because of the erratic and speculative nature of the London market business here has been almost impossible because importers and dealers are unable to do any reliable, stable, and consistent calculating.

Deliveries of tin into consumption in February are returned as 5200 tons, of which only 300 tons came in at Pacific ports. Stock and landing on February 29 were 3743 tons. The quantity afloat yesterday was 3195 tons.

LEAD

Unusual strength combined with quietness characterizes the market. Because producers in general have practically no metal for early delivery business is almost impossible. A canvas of the market by a dealer a day or so ago revealed only a little available for the latter part of March and a small amount for April delivery. There is no anxiety on the part of buyers to purchase abroad; they regard the market as too high and are only trying to buy what they need for prompt and early delivery. A fair appraisal of the market which is determined by outside sellers and producers, is 9c., St. Louis, or 9.25c., New York, for early delivery, with as high as 9.30 to 9.37½c. mentioned. Some say the latter quotation is the minimum. The American Smelting & Refining Co.'s quotation is unchanged at 9c., New York, or 8.75c., St. Louis. There is a very good export inquiry. That this will force prices still higher and cause a stampede is a possibility.

ZINC

The market is quiet and values have receded during the week. Prime Western for all positions up to July 1 is quoted at 8.75c., St. Louis, or 9.10c., New York, as compared with 9c., St. Louis, and 9.35c., New York a week ago. Demand from domestic consumers, which was fairly good a week ago, has tapered off and they are waiting and buying only what they need for nearby consumption. Some light sales were made on Monday as low as 8.70c., St. Louis, or 9.05c., New York. Foreign buying has also declined and so have prices in London which has had a sympathetic effect here. If anything the market was a little firmer at the close yesterday.

ALUMINUM

Prices of the leading interest are unchanged at 33c., New York, for wholesale lots for early delivery. Metal from outside interests is quoted for the same position at 31c., New York.

ORES

Tungsten: The market is quiet and quotations are nominally unchanged at \$6 to \$6.50 per unit for Chinese ores, \$12.50 for South American, and \$15 for high-grade Western domestic ores. There has been some buying but an active market is not expected until a decision comes in the tariff matter.

Ferro-tungsten is quoted at \$8 to \$5c. per lb. of contained metal, some sales being reported at \$2½ cents.

Molybdenum: Quotations are unchanged at around 75c. per lb. of MoS₂ in regular concentrates. Very little business is recorded.

Manganese: Foreign ore is available in limited amounts at 80c. per unit.

Manganese-Iron Alloys: Domestic ferro-manganese has again sold in small lots for spot delivery at \$200 to \$225 per ton, delivered. In one case \$250 was asked but not realized. Domestic makers are asking from \$160 to \$175, delivered, for last half or third quarter. Very little British alloy is available; the prices asked range from \$165, sea-board, up. The output of domestic ferro-manganese in February, according to the blast-furnace report of 'The Iron Age' was 16,283 tons against 18,062 tons in January. The spiegeleisen market is strong at \$57 to \$60, furnace. Domestic output of this alloy was 11,755 tons in February or practically double the January output which was 5895 tons.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A NEW 'JACKHAMMER'

The Ingersoll-Rand Co. has developed, and is offering for sale, a new design of its well-known 'Jackhammer' group of hand hammer-drills. This machine, known as the BAR-33 'Jackhammer', is smaller and lighter than other Ingersoll-Rand machines of a similar construction. It fulfills a long

Bar-33 'Jackhammer'

existing need for a light self-rotating hammer-drill. Its weight, 21½ lb., should be a very welcome feature as it permits the use of a drill in locations and positions not accessible to heavier machines.

The manufacturer recommends this light drill for bench work in soft limestone quarries; for trimming in metal and coal mines, and for pop-hole work in quarries and open-pit mines. In addition to the above the machine may be conveniently used for drilling holes in concrete and masonry foundations. This type of 'Jackhammer' is not recommended for drilling deep holes or for use in hard rock, but for drilling where a machine of extreme light weight is desirable. The BAR-33 is the fourth type of 'Jackhammer' manufactured by the Ingersoll-Rand Co. Machines of this type are now available varying in weight: 21½, 35, 41, and 70 pounds.

RECENT DECISION OF U. S. COPYRIGHT OFFICE PERMITS AUTHENTICATING NEW CLASS OF EMBLEMS

It is now possible to secure Government registration and protection for an emblem or business badge by a concern which sells brain power or 'service' as distinct from a commodity having the physical attribute of merchandise.

Organizations of engineers rendering a selling or laboratory service have in the past made many futile attempts to

register their emblems as trademarks in the United States Patent Office. The Commissioner of Patents has been steadfast in supporting the Examiner of Trademarks who held that only insignia applied to articles of trade and commerce

A Patented Emblem

might secure the benefit of Government registration. No matter how valuable the 'service' it was held that such functioning was incapable of being officially tagged or marked by a sign of origin. Thus, a wide field of endeavor having for its product a salable service or responsibility has found itself without the same protection for its badge of reputation as is accorded a canner of beans or a manufacturer of monkey wrenches. The issuance, after a prolonged hearing, of a formal Federal credential authenticating the use of the emblem embodying the words 'Truth Well Told' by the H. K. McCann Co., advertising agents of San Francisco, is of significance to those who offer for sale the product of the brain as distinguished from commodities having physical form.

After being repeatedly balked at the Patent Office, the McCann company directed its efforts to the Copyright Office at the Library of Congress. The successful plea was based on the fact that the Constitution clearly states that authors and inventors are entitled to protection for their products, and, inasmuch as the protection was refused by the Patent Office, an obligation lay with the Copyright Office to protect a class of marks in many instances very valuable. The McCann company has just secured as the reward of its efforts the official certification of the emblem shown in the accompanying cut. The primitive hewer of stone, chiseling the words 'Truth Well Told', was the emblem granted recognition. Of chief interest is the fact that a way is now open to others for certifying the crest, trademarks, or insignia of laboratories and certain types of expert service. In granting protection the Copyright Office considered both the originality and artistic quality of the mark. Bizarre arrangement alone will not always secure protection.

WE MUST STABILIZE PRICES

The Paraffine Companies, Inc., has recently sent a letter of warning to its customers on the Pacific Coast under the caption 'The Time Has Arrived to Put on the Brakes'. The company feels that forward-looking business men and citizens cannot help but realize that a halt must be called—and called soon—in present tendencies, particularly in so far

as constantly rising prices are concerned, or calamity awaits us.

"Conditions affecting the roofing industry and allied lines are abnormal and puzzling in the extreme. On the one hand the demand from the trade is larger than ever before and greatly in excess of the ability of manufacturers to supply. On the other hand, raw materials are very scarce, in fact, almost unobtainable with prices at unheard-of levels. Rags, for example, are now selling at \$85 per ton, an advance of \$30 per ton during the past six months.

"The situation in the East is even more acute than on the Pacific Coast, some manufacturers having advanced prices three different times during January. Others have withdrawn prices entirely. Others have called in their salesmen; while a number are booking orders only for shipment at their convenience and at prices in effect when shipment is made. As to the advisability—indeed, the necessity—of keeping prices down in general, there can be no argument. We, in common with thoughtful and patriotic citizens everywhere recognize that prices cannot go higher without extreme danger.

"As a result of increased facilities, our manufacturing costs are considerably lower than those of most manufacturers. Because of this fact and our sincere desire to assist in stabilizing prices generally, it is our purpose not to take advantage of prevailing conditions to exact the limit in prices. In other words, we will give our customers the benefit of our increased facilities and the stocks of raw materials which we have on hand, and will advance prices only when our present large stocks are exhausted and we have to replace at still higher prices.

"In the meantime, we advise our customers not to speculate, but to buy to cover their immediate requirements only. If the building in sight in your community indicates a demand on you during the next three months for 100 squares, 500 squares, or a carload of roofing, buy that quantity and no more, but place your order now to ensure delivery of the goods when you need them. We urge also that our customers in turn do not attempt to secure from their customers the highest prices obtainable, but that they be satisfied with a fair and reasonable profit, because, in our opinion, it is only by so doing that our mutual interests and those of the country at large can be conserved."

REDWOOD FOR TANKS AND PIPES

The Pacific Tank & Pipe Co., manufacturer of cyanide-plant equipment, mining and mill supplies, uses redwood extensively. The qualities which make it particularly desirable for the uses to which the company put it are pointed out in Catalogue No. 12, recently issued.

"Long experience has proved to thousands of satisfied users, that Californian redwood is the best obtainable material for tanks and pipe. The trees from which the lumber is cut range in age from 500 to 1200 years. These redwood forests belong to an entirely different geological period from the growth upon any other portion of the continent. There is no similar wood found in any part of the world. Redwood contains a natural preservative which makes it impervious to the destructive action of acids and alkalies. It resists decay so well that trees which have lain five hundred years in the forests have been sent to the mill and sawed into lumber. For engineering purposes in contact with ground or moisture, redwood can be depended upon to maintain its full strength and service from 15 years upward. Seasoned redwood is one of the strongest woods for its weight. It is soft and yet strong enough to resist the most severe stresses. Its breaking strength, according to the U. S. government figure, is 62% that of white oak, which is probably the strongest and toughest of American woods. Redwood actually grows stronger with age. These remarkable trees contain no pitch or resinous matter and the wood is very diffi-

cult to ignite and very slow burning even when dry. Here is what a noted fire-chief, after more than 22 years in the San Francisco Fire Department, says: 'Under similar conditions of heat exposure, redwood lumber ignites much less quickly and burns much slower than resinous soft building wood, and I am also convinced that when redwood becomes ignited the fire is much more easily extinguished than other soft building woods'."

COMMERCIAL PARAGRAPHS

Charles Austin Hirschberg, Inc., advertising counselors, specializing in the technical field, announce that they are now situated in their permanent home in the Sun building, at 150 Nassau St., New York.

O. H. Johnson has been appointed special representative for the Intermountain region of the Taylor-Wharton Iron & Steel Co., of High Bridge, New Jersey. Mr. Johnson will have his office in the Denham building, at Denver.

The Pelton Water Wheel Co. has announced the appointment of W. D. Ward as manager of its Atlantic Department at 90 West street, New York. Mr. Ward has been associated with the company for more than 25 years, having been the ranking sales-engineer in the home office at San Francisco previous to his assumption of the post in New York.

The Justinian Caire Co., manufacturers and importers of assayers' and chemists' materials, of 573-575 Market street, have just issued a 292-page illustrated catalogue. The company announces that it has in stock a complete supply of pure chemicals made by the best of manufacturers, and that while prices cannot be guaranteed, customers may be assured at all times of the benefit of the very best market rates. The specialties offered include Calkins' assay-office appliances, zinc-shavings, resistance glassware, cyanide of potassium, pure acids from the Grasselli Chemical Company, Merck's pure chemicals, and Baker's analyzed chemicals. The stock of Calkins assay-office supplies is particularly complete and the quality is the very best.

The Chemical Catalog Co., 1 Madison avenue, New York, has just completed the arrangements for the publication of a handbook or a compendium of quantitative analytical chemistry. The author is a member of the faculty of one of the universities devoting special attention to chemistry, and has had extensive experience in applied chemistry and in chemical engineering. It is planned to include every method given in chemical literature, both in English and in foreign languages. The work will be in two volumes, one Inorganic and the other Organic. The Inorganic volume will be published first. Every journal and book likely to contain methods of quantitative analysis will be carefully searched. The material will be thoroughly indexed, not only under the elements and compounds, but also under the commercial articles in which the element is to be determined. Copious references to the original literature will be given.

The Denver Fire Clay Co. operates its own fire-clay mines near Denver, and through every process of grinding, blending, molding, seasoning, and burning, the work is in the hands of experienced workmen and under the supervision of experts. All raw materials are first subjected to extracting chemical analysis and physical tests by skilled ceramic engineers and burned at definite temperatures under pyrometer control to assure the most uniform products possible. High-grade fire clay is refractory and chemically inert; when properly mixed with suitable clays and binders it has relatively great mechanical strength. By skillful manipulation, definite textures can be obtained having various degrees of density and porosity, so as to meet the most exacting and varied requirements of the mining and metallurgical processes. A recent Bulletin from the company describes the products manufactured in interesting style.

T. A. RICKARD, . . . Editor

THE report from the Industrial Conference, of which Mr. Hoover is acting chairman, is expected shortly. It is understood that the Conference will re-affirm the principles of collective bargaining; present a plan for arbitration tribunals, national and regional; endorse the 8-hour day, except for certain industries in which it is impracticable; and give a qualified endorsement of the principle of a living-wage. On page 123 we publish the text of two important statements made by Mr. Hoover.

A MEMORIAL to members of the Institution of Mining and Metallurgy that fell in battle is to be placed in the house of the Institution in London. Lieutenant-Colonel Peter N. Nissen, well known in Canada and the West, has designed a figure, which is to be done in bronze upon a pedestal of malachite. The Council asks for gifts of malachite. Will not some of our friends, at Bisbee, for example, or in other copper-mining districts, send some selected pieces of malachite to the Secretary of the Institution at 1 Finsbury Circus, London, E.C.? The members of the Institution expect to raise a fund of £4000 for this memorial.

EVIDENCE introduced in a London police court against seven persons, one of whom is described as a gold miner, shows that 110,000 sovereigns were withdrawn from the Bank of England and melted into bullion, which was then sold at a premium. This is against British law, which prohibits the use of gold coins other than as currency. Another unexpected result has been the driving of the sovereign out of circulation in South Africa by the high price obtainable for gold in London. In view of the impossibility of securing shipments of the precious metal from Australia, it has been found necessary to buy gold on the London market, have it minted, and ship the coin to the Cape. But this process of 'sending coals to Newcastle' could not last long, because the cost of the operation became entirely prohibitive when gold began to climb to a premium of 50%. It is suggested that a mint be established in South Africa, so that the gold of domestic production may be stamped into sovereigns; but even then it is not clear how the retention of the gold coins can be assured without special legislation; and as to that, it must be remembered that South Africa is a self-governing dominion, not a crown colony. Another, more commendable, result of the enhanced value of gold has been the decision to increase by 20% the pay

of all officials of mining companies in South Africa. At the same time the abnormal price of silver has led to the passage of a bill in the British parliament for decreasing the silver contents of the token coinage from 925 parts of pure silver per thousand to 500 parts per 1000. This was done after rejecting proposals to issue small notes and nickel coins. If silver should depreciate, in consequence of increased production, there will be a temptation to forge coins identical in metal and alloy. On the other hand, at the present time there is a like temptation to melt the current silver coins. Evidently the disturbance of international exchanges and the barriers to economic adjustments are creating new problems.

UNDER 'Discussion' we publish a letter that makes an appeal that cannot be ignored. A Mexican engineer, the superintendent for an American mining company, writes to ask why he should be ineligible for registration as an engineer in the United States, if he came to this country, because he is neither a citizen of the United States nor of Canada. Are we to have a closed shop for the English-speaking members of the profession, and exclude all others? If we do, have we a right to expect a free field for American and Canadian mining engineers in Mexico and the great mineral regions that extend from the Rio Grande to Patagonia? Surely this is a narrow view and an ungenerous restriction. We extend our sympathy to Señor Fernando Montijo and venture to suggest to him that the clause to which he objects must have crept into Section 9 inadvertently, or on the initiative of someone parochially minded. It was not meant to cover the professional visits or the temporary sojourn of a gentleman like himself. We confess that we do not know what this clause was meant to do, and we hope that some member of the committee responsible for it will explain to Señor Montijo and to the rest of us. American engineers practise their profession all over the world; are we to deny reciprocity?

AMONG his multifarious duties Mr. Hoover has found time to look into the stabilization of the bituminous coal industry and to start a discussion before the American Institute of Mining Engineers. This is, we believe, his first contribution to the transactions of the Institute, although he has written many articles for the technical press and is the author of a standard text-book, 'The Principles of Mining', published in 1909. In presenting

his subject, Mr. Hoover states that the bituminous coal industry functions deplorably on account of its intermittency of production. It is equipped for at least 20% above its average output and thereby involves the employment of 100,000 more men than should be necessary, and who are diverted from other productive occupations. The result is not only a needlessly high cost of coal but "a long train of human woe". It is an engineering problem. Mr. Van H. Manning, the director of the U. S. Bureau of Mines, Mr. George Otis Smith, director of the U. S. Geological Survey, Mr. H. H. Stock, Professor of Mining Engineering in the University of Illinois, together with Messrs. S. L. Yerkes, Eugene McAuliffe, and Edwin Ludlow have contributed to a symposium on the subject that ought to lead to practical results. Of course, the most direct cure for the evils of intermittent production would be storage of the coal during periods of over-production—usually in summer—as against periods of maximum consumption—usually in winter. Most coals suffer by storage, becoming inferior to freshly mined coal. Storage under water has been tried to prevent deterioration, but the cost is high. For instance, at Whiting, Indiana, it cost \$3.30 per ton to construct an under-water pit for 10,000 tons of slack. The cost of unloading the coal was 10 cents per ton and the cost of reclaiming it from the storage-pit was another 10 cents per ton. Briquetting is another remedy. A third is to burn the coal in pulverized form. Another is to use it as a source of electrical energy at central power-plants to serve railroads. We expect that the committee selected by Mr. Hoover, as president of the Institute, will be able to present some useful suggestions. It is a matter that affects everybody.

THE qualifications of a competent hoisting engineer are peculiar. At a productive mine, where several hundred men are lowered and hoisted on each shift in addition to the moving of ore and material, the requirements, both mental and physical, are exacting. The position is one of unusual responsibility. The time was when the man who ran the hoist was primarily a mechanic, who repaired and kept his engine in order, and looked after the compressor, which was near-by; but at the same time the nervous strain of actually running the hoist was not great. Now, however, in consequence of the larger scale of mining operations, together with the influence of the labor-unions, the hoisting engineer, except in extreme emergency, does nothing but manipulate the controlling levers. The duties are less varied but not less difficult. In the opinion of one master mechanic, who has had charge of dozens of engineers on first-motion hoists, a man who has never seen a hoist, but who is properly equipped mentally and physically, can develop into an expert hoist-engineer in a week. On the other hand, this same man knows engineers that have run hoisting-engines for years, in whose hands he would not trust his plant under any circumstances. The physical requirements are good hearing and sight, and general good health. The engineer gets his signals by ear; his eyes register the movement of the cages or skips as shown on the indi-

cators; and he must be free from constitutional defects, as, for instance, a weak heart, that could result in sudden disability and consequent disaster. But the prime requirement is a steady nerve and a cool head. Statistics indicate that 15% of the fatalities in and around metal mines are the result of shaft accidents, and in the majority of these, the fault rests with the man operating the hoist. That there are not more speaks well for the competence of the men, as a class, who are engaged in this trying occupation, where a mistake of a few seconds or a few inches may mean disaster, and yet where speed is essential. The fact, however, that investigation of accidents has frequently disclosed serious discoverable weakness in the engineer emphasizes the responsibility of the mine executive in choosing hoist-men. On page 421 we give a report of some intelligent steps that have been taken by the State Industrial Commission of Utah to enforce the examination and licensing of hoisting engineers.

FROM the record appearing in the current bulletin of the Institute we note that 1727 ballots were cast in favor of the increased dues and 361 against. As the maximum of votes was 2274, which was the number cast for Mr. Hoover as president, it is noteworthy that nearly 80% of those who voted were in favor of the increase, but, as there are 8000 members, the percentage voting in favor of the change was only 21%. This only shows how small a proportion of the membership takes a proper interest in the affairs of the Institute. The advocates of vagaries in spelling were overcome in the ratio of 836 to 593, whereas only 441 voted in favor of all the proposed new spellings. Let us thank Heaven that this proposal was so definitely defeated, although in this matter likewise only a small proportion of active opinion was elicited. The new vice-presidents are Messrs. Seeley W. Mudd and Frederick Laist, both of them men of the highest standing in the profession. The speeches delivered at the banquet must have been delightful to hear. Mr. Lawrence Addicks increased his reputation as a toastmaster by his happy way of introducing the speakers; it is a difficult art, and he seems to know when to stop, which is the more difficult art. We regret that the members in California should have been identified with the spelling hysteria, but then we must remember that we in San Francisco have ever been regarded as 'kickers'. Mr. Winchell continued the note of humor, from which he passed gracefully into a deeply serious talk of a most timely character, the keynote of which was the need for co-operation of effort. Mr. Hoover's speech appeared in full in our issue of February 28. After he had spoken, Mr. Addicks bestowed the 'Order of the Golden Fleece' on Mr. James F. Kemp, the presentation being an excuse for expressing the cordial goodwill and high esteem in which the Professor is held by everybody in the Institute and in the mining profession. He is not easily outdone in witty repartee and proved it by his reply, in the course of which he referred to apex litigation, poking fun both at himself and Mr. Winchell, and making passing mention of "the editorial outpourings of the little volcano of technical journalism out on the Pacific Coast". Evi-

dently we innocent and quiet people out here are winning a reputation for being rambunctious, despite the mollifying influence of a climate so unlike that described in a celebrated treatise on the "Geology of Jell," which was published, appropriately enough, in the "little volcano of journalism" just before the San Francisco earthquake. The author was able to use the petrography of Jell and even the pathology of the Devil himself for honest fun, and we hope that the "little volcano" may never extrude anything that will scorch the sunlit meadows of his generous fancy.

Mining Exploration

We note with pleasure that Mr. J. H. Farrell's article on this subject has elicited discussion. Four letters appear in this issue. They come evidently from men in the field and from different parts of the country. All deplore the passing of the prospector and the exhaustion of the easy chances to find rich outcrops. Mr. E. Hedburg thinks that the young man from mining schools ought to go into partnership with the experienced prospectors, and exchange his familiarity with actual conditions for their knowledge of technology. He thinks that the young fellows lack the physical strength of the veterans; but the main difference between them is, we think, in the stock of patience. Young men are in a hurry, and prospecting takes time, lots of time, and persistence, and optimism. As to the last, youth is rich in optimism, but the real prospector is the greatest optimist in the world. As to "geological education", we demur to Mr. Hedburg's suggestion that the old prospectors had that advantage; on the contrary, while they had a sort of common sense, which is the beginning of science, they were recruited chiefly from among the uneducated; their geology and mineralogy were scanty. If they made an important discovery they were likely to be credited with more method than luck, and some of them obtained reputations of the *ex post facto* kind that were quite fictitious. As to wild-cattening and cheating—why not use plain English—in the mining business, we doubt very much whether that has hurt prospecting, because trickery has been a part of mining affairs since the days of Agricola, who in his book describes the same old tricks as are in vogue today. No; we think that mining speculation is less spoiled by dishonesty than in the days gone-by, because a better class of men has come into the business and the incidence of the law is more effective in checking wrong-doing. Thirty or forty years ago the cruelest fakes and steals were perpetrated with impunity. The whole atmosphere of mining is less tainted than of yore. The reader will remark that we have some of the optimism of the true prospector. We may over-estimate the improvement in morals as the prospector exaggerates the value of his find. Mr. W. C. Frazier says that to this exaggeration is due much of his failure to connect with capital, and we think he is right. Those of us who have been engaged in the work of scouting for mines know well how often the descriptions given to us by honest fellows are ridiculously incorrect. Undoubtedly this excites a scepticism that is

hurtful to the business, because it breeds suspicion. If prospectors would, or could, give a plain unvarnished description of their finds, or the owners of prospective mines would, or could, tell a true story of the orebodies they have uncovered, it would save much of the time and money of the buyers of mines and of those "exploration" companies that are so readily ridiculed for their failure to find satisfactory ventures. Probably we ask too much; we ignore the frailty of human nature, when we expect the owner of a mine to tell the exact truth or something near it. "*Caveat emptor*" is a warning with centuries of human experience to give it edge and significance. The sellers of horses or of motor-cars are no different from the man with a mine to exchange for cash. Mr. G. L. Sheldon has had a large and varied experience in what unfortunately is called "the mining game" and we find ourselves in agreement with him on several points. Yes; there should be more digging and less conversation, but so long as one is more pleasant than the other there will be a disparity in their relative quantities. There is a tendency, quite natural, for the agents of exploration companies to prefer to sit in an office and examine the reports that come by post, rather than go into the mountains or the deserts in search for a rare thing, the mine that is worth more than it costs. For that is what they seek. There is also another factor, namely, some engineers are so anxious about their reputations that they avoid taking a risk. Of course, risk is inherent in mining, and the man who expects a sure thing had better do something else than appraise prospects for purchase; he might, for instance, become manager of a mine, for which work his cautious habit of mind would probably fit him better. Undue caution is probably the main deterrent to the success of exploration companies, but it must be acknowledged that men with the sure judgment or the instinctive appreciation of promising conditions are rare. It is not difficult for a properly trained engineer to make maps and take samples multitudinously and systematically, nor even to interpret the evidence as a means of estimating the ore that is assured, but it is exceedingly difficult to foresee the extension of the orebodies or forecast the future life of a mine. For that, much and varied experience is requisite, and also the kind of mind that obtains hints intuitively. Besides these qualifications there is needed another factor, namely, luck. "Faint heart never won fair lady," and young men afraid of their decisions are unlikely to make money for those who adventure in mining. It used to be thought that more money was to be made by buying prospects and developing them into mines than by buying ore that is measurable on three or four sides. If fully developed mines have come into greater demand it is because they lend themselves better to large financial schemes and the assured payment of dividends for a period long enough to permit the unloading of shares at a profit. The real sport of mining, and the most profitable phase of it, is to take reasonable chances on a number of prospects in the expectation that one or more of them will prove bonanzas. Mr. Farrell, in his article, made a number of sensible suggestions, one of them being the concentration of ex-

amination work on a promising district, instead of the mere flitting from place to place in pursuit of the will-o'-the-wisps brought to headquarters in the shape of unsubstantiated reports. In times like these when the prices of most metals are high, it should be advantageous to examine the records of old mines and the workings of idle mines, in the search for orebodies that formerly were too low grade to exploit profitably, but that now, with the aid of better prices and more efficient metallurgic methods, might prove remunerative. The discussion of this subject is well worth while and we shall be glad to hear from some of the senior engineers, having published the views of the prospector and his friends. When all is said and done, it must be remembered that the search for mines can never be an exact science while the knowledge of the geologic conditions controlling the concentration of ore in particular places remains so inexact. Mining exploration will always remain speculative.

The Hoover Campaign

In our last issue we chronicled the organization of the Hoover Republican Club of San Francisco Engineers on March 5. Before that a similar move had been made at Los Angeles, two clubs of the same kind being formed to promote Mr. Hoover's candidacy. Likewise at Berkeley a Republican Club has been organized and has held two enthusiastic meetings. On March 11 a meeting was called at the Palace hotel, San Francisco, and a Hoover Club of California was started to co-ordinate the efforts of the various similar organizations now existing in California. It is complained by the old gang of the Republican party in this State that the supporters of this movement are largely Democrats; this is not quite true, but it is true that they include many Democrats. Sentiment has crystallized in favor of an effort to send to the Republican Convention at Chicago a delegation instructed to nominate Mr. Hoover and steps are being taken to elect such a delegation at the primary on May 4. Many voters registered as Democrats in the expectation that Mr. Hoover would be nominated by that party; they will have an opportunity to change their registration by going to the county clerk's office before April 3, which is the last day on which they can make the change. The candidacy of a Republican delegation in favor of Senator Johnson at the primary has been announced; the list of names reads like a financial menagerie. Mr. Hoover's friends believe that his own State ought to take the initiative in placing his name before the Nation and they intend to leave no stone unturned to accomplish that purpose. His letter to Mr. Ralph Arnold, as published in the newspapers of March 10, gave a cue and a stimulus to such action, because in that pronouncement he labeled himself "an independent progressive". Whether it was "Progressive" or "progressive", we do not know, but the intimation, taken with his telegrams to the Democrats in Georgia and California, indicates fairly clearly his party leanings, although again he stated that he "objected as much to the reactionary group in the Republican party as to the radical group in the Democratic party". The

plan therefore is to urge the liberal and progressive element in the Republican party to nominate him at Chicago on June 7. Neither party has come out with any announcement of principles. Mr. Hoover's own speeches give all the essentials for a party platform. He is the one public man mentioned for the Presidency who has not hesitated to place himself on record on the main issues of the day and on them he has spoken clearly and courageously. He is "ready to engage in team play with any organization and leadership that has for its objective the consummation and maintenance of great issues in the forms that he believes are to the public interest and benefit". He believes in party organization, "but it must be for the promotion of issues, not of men". He is for the League of Nations, with such reservations as are necessary to "clarify the world's mind that there can be no infringement of the safeguards provided by our Constitution and our nation-old traditions". He is against any party "dominated by groups who seek to set aside our constitutional guarantees for free speech or free representation and who hope to re-establish control of the Government for profit and privilege". He is against any party that is "dominated by groups who hope for any form of Socialism, whether it be nationalization of industry or other destruction of individual initiative". Here are specifications that should suit any member of the mining profession and every thoughtful citizen. Mr. Hoover does not believe in third parties, because he has seen the confusion and inefficiency produced in European parliaments on account of a multiplicity of parties, Right, Left, Middle, Extreme Right, and Extreme Left. Our American system of two parties works better. Furthermore, owing to the provisions of the Constitution for the correlation of the executive with the legislative branches of the Government, that is, the relation of the President to Congress, it is inadvisable, to put it mildly, to have a President who is unsupported by a majority in Congress. The muddle now existing at Washington is a telling example of the results ensuing from the conflict between a President and an unfriendly majority, particularly in the Senate. To elect Mr. Hoover as President without Congressional support would be futile; it would invite an *impasse* possibly worse than the one we now face. In order that he may be effective as Chief Executive it is necessary that he be elected at the head of a dominant party. The reaction of sentiment against the Democratic party on account of the blunders made by Mr. Wilson's administration, and on account of a normal desire for change after any party has been in office for two presidential terms, is shown unmistakably throughout the country. A large Republican majority is evident. Fortunately, Mr. Hoover is normally a Republican; he has never voted for a Democratic president; he served with President Wilson only because it was his duty to uphold the national government during the crisis of a great war. He is well fitted to lead the better and more progressive element in the Republican ranks and it is proposed to place him in a position where he can do so. The first President of the United States was an engineer; it is time to select another from the same profession.

DISCUSSION

Elements of Smelting-Plant Design

The Editor:

Sir—In the second part of my article appearing under the above heading in the issue of February 7, there appears on page 200 the following statement: "The size to which a commodity is broken will regulate its weight per cubic foot, since the finer it is crushed the less will be the interstitial space." I had marked this passage to be rewritten, but somehow omitted to do so until too late. As it now stands, it conveys the impression that fine ore weighs more than coarse ore, which would be true only if, in the process of crushing, a large amount of heavy mineral particles went into the fine.

The point that I wish to bring out is that the weight per cubic foot of broken ore depends on the way in which the ore breaks. If there is a certain amount of heterogeneity in the size of the broken product, the weight per cubic foot will be more, on account of there being less interstitial space. An example will make this clear. Suppose a bin filled with ore broken uniformly to pass a three-inch ring; there will be a certain amount of interstitial space and a certain weight per cubic foot; if with this same amount of ore there had been mixed an amount of smaller particles (say, half-inch size) sufficient to fill the voids between the three-inch pieces, the volume occupied would be the same, but the weight per cubic foot would be greater.

A definition of what constitutes "broken ore" would be of assistance in interpreting the various tables on the subject.

OLIVER E. JAGER.

Nickelton, Ontario, February 16.

Engineering Employment Bureaus

The Editor:

Sir—On page 220 of your issue of February 14, 1920, is a letter from C. E. Drayer, Secretary of the American Association of Engineers, claiming that figures I have quoted are inaccurate. I therefore give you below the actual figures taken from a circular letter of the American Association of Engineers, dated November 1, 1919, soliciting new members and signed by A. H. Krom, Assistant Secretary, as follows:

"For three months period ending September 30th:

Applicants introduced	2985
Members placed	264

The corresponding figures for the same period for Engineering Societies Employment Bureau are:

Applicants introduced	5909
Persons placed	375 upward

As Engineering Societies Employment Bureau gives its services to members or non members of any society, there are always a great many people who secure positions but do not report them. Our record of persons placed is, therefore, only a fraction of the actual number who secure positions through the Bureau.

BRADLEY STOUTINGTON.

Secretary.

New York, February 28.

An Explanation

The Editor:

Sir—Your editorial of February 28 calls to my attention the fact that Mr. E. G. Lewis, publisher of the "Illustrated Review" has published a "report" by myself on the Montana oil-fields. Never having made such a report, I naturally have been a little curious until today when I secured a copy of the "Illustrated Review" and find that Mr. Lewis has published, with a few typographical errors, a letter written to him by myself on December 21 last. The closing words of which are, "Please accept this letter in no sense as a report. It is merely a few lines to keep you abreast of the situation." The weird sentence, "The formation bed is lime and the cap rock is soft shale", to which you properly take exception should read, "The formation *between* the lime and the cap rock is soft shale". When so read, it explains the reason for the 40-ft. cave at the bottom of the well. You will note also that the printer has made more or less of a mess of the paragraph preceding the above, but in spite of the resulting bad grammar the meaning can be determined with a little study.

Since you have used my name in your editorial I would appreciate your giving publicity to the above correction.

Roundup, Montana, March 3.

C. E. GILMAN.

Registration of Engineers

The Editor:

Sir—The committee appointed by the Engineering Council recommends in its report of a uniform registration law for engineers, Section 9, Clause 2: "Provided, however, that no person shall be eligible for registration who is under twenty-five years of age and who is *not* a citizen of the United States or Canada." Is there a valid reason for including Canada and excluding the rest of the world? Is there a valid reason for prohibiting a Frenchman or a South American, etc., from practising engineering in the United States, if he is fully proficient in his profession and speaks and writes English as well

as the average American engineer? Surely there must be quite a number of foreign engineers, members of American engineering societies, now practising, that must emigrate upon passage of the law, if they choose to remain loyal to their native country. What if Spanish-American countries should pass a registration law prohibiting all Anglo-Americans from practising, unless they became Argentinian, Chilean, or Mexican citizens, as the case may be? There is no likelihood of any such law on account of the scarcity of engineers in Spanish America, but, should advantage be taken of the fact, in justice? Hoover, and how many more eminent American engineers, would have been excluded by a similar law from practice in foreign countries. And, after all, what is there against allowing a law-abiding and respectful foreigner to practice his profession when residing in any State of the Union? Is the object to take away entirely, gradually, with all alien residents?

FERNANDO MONTLIO.

Mexican superintendent of Las Chispas property of the Minas Pedrazzini G. & S. Mining Co., an American company.

Arispe, Mexico, February 27.

Mining Exploration

The Editor:

Sir—Conditions in the mining districts, all over the country, have changed so much in the last thirty years that people cannot help notice the vast difference. Mr. J. H. Farrell's article in the 'M. & S. P.' sounds the keynote, which undoubtedly indicates the present trend.

On the other hand, from all sides we hear of the demand for mines and prospects. The surplus of Eastern money caused by the large war-profits of the past years has been seeking an outlet. Probably more money is available for investment in mines than at any time during recent years, but the mines are not being found. "Why is it?" we ask. Because the conditions have changed, the old productive mines are worked out, and not many new ones are being found. The old prospector and his burro are gone, there are very few left in the hills. The prospector of the 'seventies and 'eighties undoubtedly found the mines, as is shown by the records. They were men with experience, brains, and brawn, and not a few had a geological education, but endurance was their main stock in trade. So the first thing they did was to call on local merchants for a grubstake, on a basis of 50-50, secure the pack-burros, and strike out for the mountain and desert. When they arrived at a likely place, they would camp and start to prospect, always going hillward to follow and trace any float to its vein, from where it may have broken off and worked down the hillside. The vein found, the next procedure was to examine it carefully, break off samples, rub the rock and horn it, for free gold or other metals. I have known prospectors to be experts at this, and to be able to tell values from five dollars per ton up, from vein-matter, or from one dollar up on panning gravel.

Having found the prospect satisfactory the next thing the prospector did was to sink a 10-ft. hole and put up the location monuments, select a camp-site, and develop water for camp use, finally settling down to the developing of the mine by sinking shafts and driving tunnels. Occasionally he traveled back to some town for supplies as needed, and often he had to hunt straying burros for days, or carry a limited supply on his own back for want of other means of transport. I have known prospectors to do over one thousand feet of work on a single claim, and in one specific instance to sink a shaft one hundred feet in depth and do it all alone, by climbing out to hoist each bucket of rock or ore. Those men found the mines of old and they were all real he-men, who are now passing away.

The reasons for the lack of prospecting are three. The large exploration and mining companies require developed mines, with the ore-supply blocked out, for which they are willing to pay according to the amount of ore assured. The prospector is hardly able to develop a mine to that stage of showing. To illustrate, in 1913 one of the large mining companies reported that 639 properties were submitted to its engineering staff and that 538 were rejected on examination of data and reports. Eighty-two of the others failed to pass the field examination, and out of the remaining 19, two properties were taken over on long-time option with an arrangement to pay for the mine out of the profits made.

Is there any wonder that prospecting is declining? It is now impossible to go to a merchant in any town and ask for a 50-50 grubstake. They will laugh at you; they have lost all faith in the mining game.

Another reason is that the public still remembers the wild-cat speculation of the 'nineties caused by unscrupulous promoters, which were exploded by the national magazines. It was a game for robbing people in the East by their own friends or acquaintances, using the mining industry as an excuse to sell stock. The result was that it tended to put legitimate mining in bad repute and was the cause of several States passing blue-sky laws for protection. That has hurt the prospecting more than anything else; the public look with suspicion on any new venture in the mining line.

And last, but not the least, now that the superficial rich deposits have become rare, the prospector may only expect to find deposits so low grade as to be unprofitable to his own limited means of exploitation. Truly in many ways the independence of the prospector is gone, for he finds something that is of no use to him for payment as he goes, and the public is not willing to put up for the expense of developing low-grade deposits, which in most cases would make profitable mines when once opened. The only course left for the prospector is to work in some near-by mine for day's pay and accumulate enough capital for developing his prospect. This is frequently done, when no other means is at hand. The prospector is absolutely necessary to successful mining, for it must be the prospector who originally finds the property for the engineer who scouts for the capitalist. No corporation can require from its employee the endurance of such hard-

ships as are cheerfully undertaken by the prospector when the gain to be made is his own or to be shared with a few individuals or partners. On the other hand, the young engineers turned out of schools in many parts of the country are not fitted to undertake prospecting, as they lack the practical side of the work; neither have they the required endurance or brawn. Bear in mind that you cannot find and develop mines in an Eastern office-building, neither in sleeping-cars nor high-powered automobiles; so my advice to young engineers when out of school is to come out West if you possess some means or backing, and want to make a success in the mining game, to go into partnership with some good practical prospector of the old school, and prepare to rough it. It will promote your health, give you needed experience, and possibly satisfactory remuneration, at the same time you are helping in a good cause, to assist the prospector and the finding of new mines. You will by this means re-establish confidence in the mining industry with the folks at home by being right on the job yourselves. And do not look to the mining companies for a job, as is usual with engineers when just out of school, because they are over-run with applications from students. In one case a young engineer, a friend of mine, sent out 200 inquiries to mining companies. All answered that there was no chance for a place immediately but to inquire again some time in the future—a poor consolation at best. So, therefore, with the education and some means or friends, there are unlimited possibilities in the field of prospecting for the precious metals.

E. HENNING.

Kingman, Arizona, March 1.

The Editor:

Sir—I have just read the article by J. H. Farrell. He only touches a few of the high places; he is good on mining-camps and near-by properties. The poor old prospector that goes miles from any known mineral deposit and opens up a good grade of ore is out of luck; when he starts out to get money out of his discovery, he is told on every side that the locality is not known as a mining country and Mr. Tapeline has no interest in the poor devil, especially if he hasn't something that he can get his tape all the way round. I have been twenty years where I am now writing this and have looked California over well for money on a cinnabar property on a royalty basis or otherwise. Cinnabar is about the poorest mineral to raise money on among the minerals of any real value, and is usually ready cash on 30 days, or less. One drawback is that there are seldom large head-lines in the papers, like an oil excitement or a big gold strike, to create a rush and start the man with money to thinking. There is over 1000 acres in this part of California to be had for a song compared to what is paid for property out of this State. In some places it is easy to bond mines for large sums of money. They even pay more on a bonus for oil than they would be willing to pay as a purchase price for mineral land in California. This State has produced more quicksilver than gold; there is a well-known stratum on which all the big mines are or have been.

I cannot understand why there isn't money to be had to open up a fair showing on this big producing stratum. Just think what the Almaden quicksilver mine has done. This country has produced thousands of dollars worth of quicksilver from workings on a small scale and in an expensive way. There has been about \$100,000 worth of ore taken out here in a place about the size of a small two-story house, while a pocketful of picked ore from other places sets the country wild and money comes by the millions to buy all there is to be had with large payments down on supposed mineral land. I have failed to find engineers that know cinnabar property when they see it. Of course, they know the ore, but nothing of how the formation should lay for a good producer. They are only ready with their tape when they are shown ore and care no further about the property. I would like to give the man with the \$5,000,000 a good talk on cinnabar, California is down to 15,000 flasks of quicksilver for the year 1919. This county can produce that for the next 25 years. We have the formation on the big producing stratum and no money to open it up when they can get it for less than half its value; you do not know that men of money try to starve the prospector out so as to get the property at five cents on the dollar.

C. F. FRANCIS.

Parkfield, California, March 1.

The Editor:

Sir—The article by Mr. Farrell sure strikes the keynote, when he says to "dig more".

The deposits of mineral are not all opened up yet by a long way. But how to get money to do it is indeed a problem. Most prospectors make the mistake of very much over-estimating their finds. These times no one will purchase a prospect without sampling it, and when the assays are in from the sampling, and returns scarcely show 10% of the claimed value, the deal, of course, is off at once.

A prospector cannot be blamed for hoping he has a good thing. But so many of them are away beyond hope that when someone does come along that would do something with it, if the showing justified, there is so much difference between hope and reality that the deal is off before it has scarcely begun. Someone has said that there are liars, there are damned liars, there are prospectors, there are promoters, there are fiscal agents, and there are smelters.

There are prospects of promise that it would be impossible to make a report on that would even interest an engineer sitting at his desk. I know of one property that is tapped with a tunnel at the 100-ft. level, in perhaps 125 ft., stoped to the surface. The vein averaged 16 in. wide, and milled an average of \$100 per ton. But there is practically nothing left above the tunnel-level. Below this tunnel, 163 ft., there is another tunnel, in 130 ft., in country-rock, parallel with the vein. On which side of it the vein is no two can agree. Below the upper tunnel there is a winze sunk 26 ft., 4 by 4 in. size. From this there was taken 10 tons of ore that milled \$160 per ton.

The time was when men would put money in such a

prospect. The price is right and the terms are right, but a report cannot be made on it that will attract an exploration company enough to send a man to look at it. Digging is what it needs.

There is another on which there are two shallow shafts, about 400 ft. apart, on the same vein. The shafts are perhaps 12 to 14 ft. deep, and the vein exposed is something like 2 ft. wide. Five wagon-loads of the ore taken out was hauled off and milled. It produced \$2200. 400 ft. in depth could be had on this easily, but it lies there from year to year, waiting for someone that doesn't seem to come along, that will do some digging in it.

What we are all looking for is someone that will tell us how to get the men with money to open up a property, like the above, that would be classed as a mere prospect, but where digging might develop a paying mine.

W. C. FRAZIER.

Nampa, Idaho, March 2.

The Editor:

Sir—Referring to the article by J. H. Farrell, this is the best thing published on this subject in years; it is good 'horse sense'. If mines are to be found, it must be by work; 'dig' is the word. They cannot be found today by sitting in the office reading reports.

The policy followed in late years by the large operating companies gets few results. The fact is that nine out of ten mining engineers turn down a mine or prospect if there is the least doubt of its being a success. They figure that this is safe, because it is easy to say, if it makes good later, that there was not sufficient work done to be able to decide, when it was examined. Again, it often happens that their field experience has not been sufficient to enable them to judge, compare, and form an intelligent opinion. Very few have the courage to express their opinion on a prospect, if inclined to favor it.

There are no developed mines for sale today, at a fair value.

In 1910, in Mexico just prior to the revolution, we had a scheme about completed that ought to win. Some New York people agreed to put up \$250,000 and a company was organized. A man was picked out who was familiar with a certain portion of a State in Mexico, who had had a large field experience, regardless of whether he was a technically trained man or not; but he must have had a varied practical experience, and become familiar with his district. He was to pick out or select a prospect or partly developed mine, the best he knew, securing it on a bond and lease upon as favorable terms as possible. The head engineer, a man of large field experience, of mature years, and of good judgment, would examine and pass upon it. He would recommend the expenditure of \$1000, or \$5000, or whatever amount appeared advisable, as work progressed, for development as both engineers agreed. At any time that such development showed the conditions to be unfavorable to the making of a mine, we would quit. But, if after the expenditure of \$5000, they both agreed that the chances were still favorable, then the work would be continued. The point being, that whenever they (with any other members of the association

in consultation) agreed that the conditions were so unfavorable as to leave no chance of success, we would quit it and try another prospect. There were to be ten of us in the field in various parts of northern Mexico. In those days the peso was worth 50 cents in U. S. currency; labor was cheap; it was considered that the original capital, equal to \$500,000 Mexican, should be divided among ten districts, and that on the average \$5000 Mexican would probably determine whether to abandon a property or not; thus giving us 100 chances. We thought that with good judgment in selection and proper management, the chances of our securing one or more real mines were excellent.

In that event we would win; we would be ahead of the game, having secured a good mine at a less price than it could be bought. Each of the ten field-men had a stock interest, expenses, and a nominal salary. The idea was that we were all working for our own interests, so we would keep down the overhead expenses (only the consulting engineer). As soon as a mine was found warranting a large expenditure, those who put up the original capital agreed to finance it under a separate corporation; all of us obtaining a block of stock in the new company. A proposition along similar lines ought to win in the United States today. Let the consulting engineer select the areas for work on the basis of previous history, production, and geological conditions. Then pick out a hard-headed man of practical experience in that particular section (if a technical man, all the better, but he must know his district well). Enlarge the scheme by operating in several different States or sections. Put the money in the ground, economically, at least until such a time as the mine is on a dividend basis.

I believe that the results obtained would be far cheaper than the mines found and purchased by the large companies. It is the exception to see a report that warrants the cost of an examination; but we often see one in which the geological conditions are good; but perhaps not sufficient work has been done, or it is old and now caved in, or it is impossible to get a clear understanding of the conditions. Few owners appreciate the necessity for having a good report upon their property. Mutual interest, co-partnership along the above lines, cutting out large overhead expenses, should win.

The main thing is that 'digging' is done.

Denver, March 4.

G. L. SHELTON.

THE most important uses of zinc are as a constituent of the alloy, brass; in galvanizing; as structural sheet; and in the desilverization of lead bullion. The consumption is greatest in galvanizing. A wide list of miscellaneous uses for zinc includes the chemical, rubber, paint, electrical, and metal industries, and medicine. The chief use of zinc ores is, of course, for the manufacture of spelter, but an increasingly large amount is used in the United States for the direct manufacture of zinc oxide and other pigments and zinc-dust. Blende is an important source of sulphuric acid, a large tonnage of which is recovered as a by-product in the making of spelter.

The Electrolytic Zinc Plant of the Judge Mining & Smelting Co., at Park City, Utah

By L. S. AUSTIN

This company, under the management of G. W. Lambourn, over two years ago, built this plant for treating one of their concentrator products, at this time sold with difficulty and at a high cost for treatment to zinc-smelting works in the Middle-West. It boldly undertook this at heavy expense to make itself independent of smelter-rates and that it might realize full value upon the tailing left after extraction of the zinc, which, freed from zinc and low in silica, then became a desirable product for smelting.

The plant is situated in a small canyon about a mile east from town where a suitable flat was available as a site. It is reached by a spur railroad from the main line at Park City, so coal can be brought in, and so that the tailing or residue, one of the sources of profit, can be shipped away to one of the silver-lead smelters in the Salt Lake valley.

The material treated is zinc-concentrate, one of the products of the Judge concentrating mill. It contains 35% zinc, 8% iron, 5% silica, 31% sulphur, 3.5% lead, with about 15 oz. silver per ton. Besides these there are small quantities of copper and cadmium, impurities that have to be separated from the final zinc solution before it is electrolytically precipitated. There are two kinds of concentrate: from the jigs and from the tables. The table concentrate is sent direct to the roaster, while the jig product, too coarse for proper roasting, must first be ground. About 30 tons of the two, principally the tailing-concentrate, is treated daily. It is hauled by team two miles to the electrolytic plant.

About the first day of May there was a strike for increased wages at the plant, which was shut-down in part because of the strike, in part because of the unsatisfactory condition of the zinc market. The strike difficulty, I hear, has been composed, so that, when roaster repairs have been made, the plant will again be started. It is claimed by the management that the plant has only just paid its way, but the recent rise in the price of zinc and of silver should encourage future operation.

The jig-concentrate, amounting to about 20% of all received, is dumped into the boot of an elevator, which takes it to the feed-hopper of a cylindrical revolving dryer for the removal of its contained moisture. This fits it for dry-grinding in a Hardinge ball-mill, where it is reduced to suitable size for roasting.

As it comes away from the ball-mill it is raised on a belt-elevator to spill upon a horizontal belt-conveyor, discharging upon the drying-hearth or top of the Wedge roaster.

The main portion of the roaster-feed is the table-con-

centrate, which is elevated by a skip-hoist to the roaster feed-hopper.*

The ore received an oxidizing roast at a temperature of 700° C. in a seven-hearth Wedge roaster of 25-ft. diameter. There are two opposite fire-boxes, coal-fired, at the sixth hearth, the seventh hearth being devoted to the cooling of the ore. The products of combustion escape by the side-flue at the upper or first hearth, although they may also be drawn off at the second hearth if desired, both exits being dampered. The greatest heat is at the second, third, and sixth hearths, and the rabble-arms on these hearths are water-cooled, while the others are air-cooled. The hollow central shaft has a step-bearing, riding on two hardened steel discs, all in oil. It appears that the older way, that of carrying it by means of idler-rollers, has been abandoned, owing to the irregular wear. The driving is done by a motor, through a double-cone variable drive and a train of gears to the bevel-pinion that meshes into the master-gear below.

At this elevation, of 7200 ft. above sea-level, the vigor of burning is less than at the electrolytic plant at Anaconda (5500 ft.), where, under steady firing, there would be danger of the formation of zinc ferrite. I am disposed to compare this with the great difficulty of roasting at Leadville at the elevation of 10,500 ft., and with smelting in the high Andes, where, as the air becomes thinner, the same trouble occurs. One is tempted to compare this condition with what occurs in the operation of air-raft. Thus, the De Haviland plane has a speed at the ground of 125 miles per hour; at 6500 ft., of 120 miles; at 15,000 ft., of only 113 miles per hour.

The hot, easily-running calcine is discharged by a steeply inclined 4-in. pipe to the Baker cooler, a cylinder resembling a tube-mill. This revolves partly immersed in a tank containing water, whose level is nearly up to the 12-in. feed and discharge openings, and where cooling is effectually done. Within the cylinder, a row of deflecting blades, or rabbles, moves the calcine along to the discharge.

Here is a product with most of the zinc in the form of zinc oxide, a little of it as sulphate and sulphide, and the other bases thoroughly oxidized. It is charged into one of two Pachuea vats, operating separately, where it is

*One might expect a hanging up or bridging of a moist product, especially in a hopper with a bottom slope of about 40°. However, that seems to cause but little trouble in the feed-chute. It may be recalled that in the Wedge roaster, to feed the material, a finger, attached to one of the rabble-arms, sweeps through the talus of ore at the mouth of the feed-chute, pushing it upon the hearth.

agitated by compressed air with addition in the vat of a sufficient quantity of acid solution from the stock-solution vat. The zinc oxide is dissolved as well as part of the copper and cadmium.

The well-agitated product, a mixture of sand and slime, passes on to a drag-classifier, where the sand is removed, while the overflowing slime goes to a Dorr thickener. This yields two products, a thickened underflow or spigot-discharge for the Oliver filter and a clear overflow. The sand from the drag falls into a bin to be shipped away for smelting.

At the Oliver vacuum-filter the thickened slime, in the proportion of two of water to one of slime, is filtered to yield a product, apparently solid, but still holding 40% moisture. It is this that is shipped to the smelting works, containing in the dry slime 20 oz. silver and 0.02 oz. gold per ton with about 6% lead and 5% insoluble. The smelter objects to the high moisture in this product, but, mixed with granular concentrate or fine ore, it should make excellent briquettes.

We come now to the interesting point, the removal of the dissolved copper and cadmium, not only in the overflow from the Dorr thickener, but in the filtrate from the Oliver filters. Until the copper and cadmium are removed, the solution is not ready to go to the electrolytic vats, since there these metals would be then deposited with the zinc. Therefore, the united solutions go to another agitation tank, and with the addition of zinc-dust (particles of zinc in metallic form) are intimately mixed until the impurities are precipitated. The reaction completed, the mixture, dust and all, is passed on to one of the two Sweetland filter-presses having 36 leaves of the disc type, 3 ft. in diameter. The quantity of zinc-dust and precipitate is but little, so that the filter is opened only every other day, sprayed clean, and again closed for action. The clarified solution is pumped into one of the three solution-storage vats, each 20 ft. diam. by 18 ft. deep, ready for use in the tank-room.

To recover the cadmium, the precipitate, after removal of the zinc-dust, is dissolved in dilute sulphuric acid, and the cadmium is electrolytically precipitated. The result is a pure white metal of 8.6 specific gravity, zinc being but 6.8.

The tank-room, 50 by 160 ft., has 120 vats in 12 rows. The anodes and cathodes in a vat are in parallel, the vats themselves in series. There are 18 anodes and 19 cathodes per vat, each exposing a surface 2 by 3 ft. to the electrolyte. The current resistance between anode and cathode is 4 volts, making the total 240 volts at the generator. The vats are graded, so that each set of five vats has its cascade to the last one. In addition, a further supply is obtained by an overhead pipe that may be passed into the flow at any desired vat, or into all of them. The anodes are lead sheets, the cathodes aluminum ones, each 21 by 36 in., hung at two-inch centres.[†] In the

tanks the zinc deposit is built up to over $\frac{1}{16}$ in. thick in two days. The cathodes are then removed from the bath and this coating is stripped from the cathode.

There are two motor-generator sets. The current coming in on a line at 40,000 volts in order to drive the motors is stepped down to 2300 by stationary transformers. The two generators develop 10,000 amperes at 250 volts or 5000 amperes at each set, that is, 25 amperes per square foot of cathode area.

Anyone acquainted with the melting of metallic zinc knows the difficulties that arise from the extended surfaces presented to the oxidizing influence of the air in melting, and how difficult it is to avoid drossing. At this plant there is used a small reverberatory furnace with hearth-dimensions of 5 by 8 ft. and about 12 in. deep to the sill of the side-charging door. The sheets are charged, and are melted down in the closed furnace with a reducing flame, then dipped into molds holding 50 lb. each.

THE PRODUCTION of metallic sodium and the various compounds or salts of sodium in the United States in 1918 was 10,198,842 tons, valued at \$142,682,575, according to R. C. Wells, of the U. S. Geological Survey. This was an increase of only 34,000 tons in quantity but of \$10,000,000 in value over the corresponding figures for 1917. Detailed figures showing the production of each individual compound, together with short descriptions of the methods of manufacture, uses, exports and imports, and other related information, are contained in a publication issued by the U. S. Geological Survey as a chapter of the Geological Survey's volume on 'Mineral Resources of the United States, 1918'. A copy may be obtained from the U. S. Geological Survey, Washington.

THE Irvinebank Co.'s tin-dressing plant and smelter at Irvinebank, North Queensland, which is 110 miles from the seaport of Cairns, has been purchased by the Queensland State government for approximately \$100,000. The plant comprises a 50-stamp mill in 10-stamp batteries, blacksmith shops, forge and machine shops, and repair sheds. The works are lighted throughout by electricity. Belonging to the property are three locomotives with the necessary rolling stock, and a tramline 14 miles long to the nearest railway station. Irvinebank is situated in the centre of a district in which lode-tin is found in large quantities.

THE most important source of silver in the United States is Butte where it is produced chiefly as a by-product from the electrolytic refining of copper, and from the residues produced in the smelting of zinc concentrate.

ventional way. Thus, the revolving disc, 3 ft. diam., would have but 40% of its area exposed to the solution, or 7 ft. square, compared with 2 by 3 ft., or 12 sq. ft., for the hanging anodes. On the other hand, the revolving anode, because it was constantly moving through the electrolyte and so exposing fresh impolarized surfaces, had certain advantages.

[†]When the plant started the cathodes were revolving discs moving between the anodes. This was later abandoned because of trouble arising from short-circuiting and from the small area exposed; then the anodes were hung in the con-

NO. 12 SWIFT AND FITTER WITH WIDE-LEAF SPACING, AS USED IN THE JUDGE MILL

THE SAME, SHOWING CHUTE BELOW FILTER FOR RECEIVING THE CAKE WHEN DISCHARGED

The Ore Deposits of Mexico—I

By S. J. LEWIS

INTRODUCTION. The ore deposits of Mexico, to those of us who are engaged in metal mining, are the most fascinating features of the country. It is the aim of the present papers to set forth briefly some of their important characteristics, as they appear in the light of recent research in economic geology.

Problems of origin, enrichment, and alteration of ore deposits are being studied today with increased interest owing to the recognition of the part played by chemical agents in the making of ores. Much laboratory work is being done, with the microscope as well as with reagents, and conclusions of great importance are being approached or indicated. These conclusions are seldom easy of compact non-technical expression, especially as they relate to isolated steps in a series of experiments. The leading students of the science, in presenting their work in the technical press, generally address the limited audience of their fellow-investigators instead of the mining profession in general. The conclusions reached in such work are subject to many limitations and reservations, and it is difficult to make a plain statement of opinion without finding oneself plunged into controversy. Nevertheless, it should be possible to express in clear language such of the progress as has crystallized into clear thought.

As a practitioner in the special field of metal mining in Mexico, it has occurred to me that most men engaged in mining would be interested in a brief exposition of current scientific thought concerning the origin of ore-bodies, so correlated with the geologic history of the country as to form a continuous narrative, and taking nothing for granted as to the knowledge of the reader. Illustrative examples will be given of the different types of mines in the country, and coal and oil will be omitted from the discussion, as belonging to a special field of their own.

CLASSIFICATION. Our knowledge of the geology of Mexico is based upon reasoning from scattered and imperfect records. These records, in the form of strata and fossils, are seldom available for study for three reasons: first, during a given period, conditions will only accidentally be favorable for such stratification as will furnish a continuous record of the period; second, after it is completed it will be saved only by accident from destruction by the igneous agencies that have been so active in the region to be described; and lastly, if formed and saved, it may be covered either by later sediments or by volcanic outpourings, and only in places will erosion or other agencies expose the formation for our study. The successful study of any district therefore is based on the patient collection of all possible observations, imperfect as they may be, each represent-

ing a mere glimpse of what has happened. It is from the assembly and correlation of these glimpses, fitted to each other by intelligent conjecture, that we get a composite picture of the geology of the country.

In geologic study, time is measured in much larger units than those employed by the recorder of human affairs. For the natural forces of erosion, wind motion, or evaporation to make even the smallest impression in their allotted work of tearing down and transporting rock-masses, the years must be counted by the thousand. When we speak therefore of recent geologic time we mean two or three hundred thousand years ago. It is in this Recent period that practically all of the visible progress has been made in preparing the globe for human habitation. To us, naturally, that seems the chief end of the whole process of nature.

Our necessarily artificial classification of geologic time into periods has a perfectly sound basis in the alternation of volcanic activity with periods of rest, during which breaking down of the surficial rocks may cause deposition of sediments. Such volcanic action, in the shape of eruptions, of outpourings, or of intrusions of igneous masses into already existing rock structures, has been recurring intermittently from the earliest periods recorded. As soon as the disturbance is over, the agencies of destruction and transportation begin their work of taking material from the existing surface and carrying it to some other point lower down. The period of rest from igneous activity therefore results in the deposition of sediments in the low-lying areas; and as settlement takes place under the sorting action of either water or wind, the sediments assume a definite character of their own, making a record of the period. As soon as volcanic activity recurs, some of these sediments are disturbed, others destroyed, others are covered by ash or lava; and the period is ended, with a new one beginning as soon as the eruptive disturbances are over.

The accepted classifications distinguish between four great time-divisions of geological history: first, the period of Ancient Rocks, the Archeozoic and Proterozoic eras, periods so vast in time, of such intense and prolonged vulcanism, and of so few fossils remains, that our knowledge of them is still largely conjectural. In Mexico these rocks are old granites, gneisses, and schists, unconformably twisted and altered, like the Archean complex, to which they are generally referred. Between this and the second grand division, that of Old Life (Paleozoic), there is a great gulf fixed. From the earliest stage of Paleozoic time (the Cambrian) to the present day everything is more definite; prior to that period we have the enormous time-spaces, as yet imperfectly

understood; it has thus become convenient to apply the name Pre-Cambrian to rocks believed to belong somewhere in the Ancient series, but whose correct place it is as yet impossible to fix accurately. In the third and fourth grand divisions, the most important by far to Mexico, we include all the periods of Modern Life, the Mesozoic and Cenozoic of the text-books. We shall find that while the older ages are represented here in small areas, the last two periods, those of Modern Life, completely dominate our horizon and make Mexico a new country in the fullest geologic sense.

The Paleozoic is represented by intrusives later than the Cambrian, belonging to a time as yet not fixed precisely. They are chiefly rocks of granitic appearance, and are widely scattered through Pacific Mexico in small masses, except in Lower California, where they cover half the State. Similar intrusives occur in Chihuahua, Sonora, Sinaloa, Durango, Tepic and Jalisco, Guerrero and Michoacan, Oaxaca and Chiapas. There are also small Paleozoic areas (Devonian and Carboniferous) in the Yaqui River valley of Sonora, in northern Lower California, and on the border near Bisbee. Every-

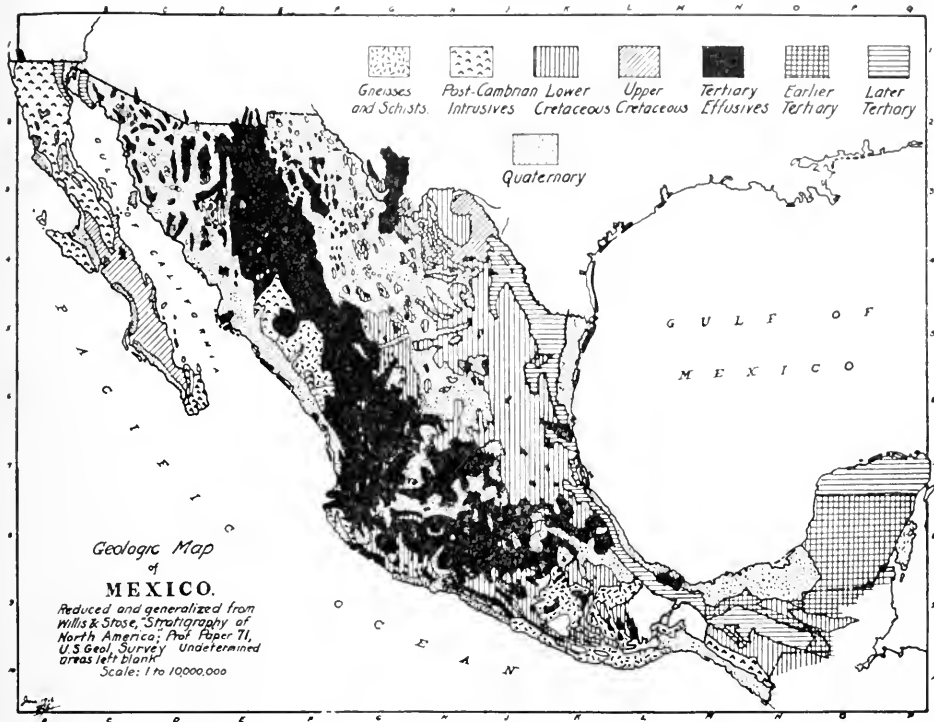

Fig. 1

The Pre-Cambrian period in Mexico is represented by the rocks already mentioned, and by hardened and altered sediments, in small areas scattered along the western axis of the country, from Sonora down through Puebla and Zacatecas, by larger spaces in Michoacan, Guerrero, Durango, and Sinaloa, and by important areas in Oaxaca.¹ Many of them have been described as Archean; some, it is thought, may be Paleozoic or even later. Hence the preferred designation is Pre-Cambrian. There are some gold veins in these formations, but of minor importance. Perhaps the chief feature of interest for us is the fact that the ore-bearing veins, found in overlying later formations, are apt to pinch, impoverish, or disappear on reaching the very old rocks.

¹"Stratigraphy of North America"; Bailey Willis, Prof. Paper No. 71, U. S. G. S., 1912.

thing else in Mexico, and practically everything in the nature of widespread and thick formations, belongs to the later periods, the Mesozoic and the Cenozoic, the periods of Modern Life.

Of the Mesozoic formations, the Triassic and Jurassic are not of great interest to us, although to the student nothing could be more remarkable than the development of the huge reptiles and birds of the period. The second part of the division, the Cretaceous, holds for us first place in economic importance.

There is a small Triassic area at the southern boundary of Coahuila, a narrow strip in Nuevo Leon, and there are insignificant areas in Chiapis and on the Oaxaca-Puebla boundary. Later than these are the small and scattered Jurassic areas, one at the junction of Coahuila with Durango and Zacatecas, two in San

Luis Potosi, one in Puebla, one in Hidalgo, and two in Oaxaca; all small, but sometimes of importance from their association with mines. On top of these rest the great limestone deposits of the Lower and Upper Cretaceous, and on top of these the outpoured volcanic rocks of the Tertiary.

The Cenozoic period, the last grand division, is conveniently, but loosely, divided into Tertiary and Quaternary time, the former being the earlier two-thirds of the era, the period of sustained volcanic action on a scale more enormous than any since the beginnings of the Paleozoic. The later, or Quaternary, is the period of the present day, geologically speaking, covering the advent of Man on the earth, and bringing the succession up to our own time.

The Tertiary period is next in importance to the Cretaceous, in Mexico, and between them they cover the greater part of the country. The Quaternary deposits, covering much of the West Coast and part of the Central Plateau, are also represented on the Gulf Coast, and as regards area, are third in importance.

It will be evident from the foregoing that the older formations were well represented in Mexico prior to the Cretaceous, but that the mantles of limestone rocks deposited on them during that period, followed by great outpourings of volcanic rocks during Tertiary time, covered all the old topography, leaving the then visible Mexico as a new country of limestones and eruptives. Subsequent tearing-down by atmospheric and climatic agencies has uncovered the old formations in the scattered localities listed, and at the same time has caused the deposition of waste material—the modern Quaternary beds. A sufficiently correct grasp of the general geology of the country will be obtained if it be understood that practically all of the eastern half of Mexico is Cretaceous, Lower and Upper; that in the Central region, about half-way to the Pacific Coast and down to Guerrero, stretch the Quaternary sediments, including a strip on the Pacific Coast itself and one on the Gulf Coast; and that the Tertiary lavas cover the whole mountain chain or Cordilleran region, forming the axis of the continent. The Quaternary, therefore, lies between the Cretaceous and Tertiary areas, and is made up in large part of broken-down material from both.

CRETACEOUS. In Mexico this period is represented by the Lower Cretaceous or Comanchean, the Eo- and Meso-Cretaceous of the Mexican Geological Survey. The Upper Cretaceous "while present is less wide-spread and less thick than the preceding system."² The period is as complete in North America as in Europe; "the Arkansas-Texas section shows the presence in America, as well as in Europe, of a most perfect section of Cretaceous deposits—which embraces all Cretaceous time."

For Mexico, the Lower Cretaceous is a peculiarly interesting period. The North American continent as a whole was mostly above water, the general submergence

being considerably less than during the Upper Cretaceous. In Mexico, however, this relation was reversed; the country was almost entirely submerged, there remaining only the peninsula of Lower California and a narrow barrier of land on the Pacific Coast, which kept out the waters of the western ocean. The slow subsidence of material to the sea-floor, continuing with but slight disturbance for thousands of years, deposited strata of enormous thickness. Estimates range from 10,000 to 20,000 ft. according to locality.¹ Although this has been exceeded in isolated localities in California, the development of the Lower Cretaceous as a whole was more complete and more remarkable in this country than anywhere else in the world. It will be recognized that whatever the Jurassic topography may have looked like at the beginning of the Comanchean, it must have been completely buried by the limestone deposits, just as snow fills up a hollow. It is for this reason that the areas earlier than the Cretaceous are confined to the small and isolated groups enumerated above. They are all that is visible of the buried masses.

The end of the Comanchean was marked by a strong warping of the continental surface, bringing the western axis high out of water and temporarily elevating most of Mexico, so that erosion and wind action could come into play. This continued for an era sufficiently prolonged to give rise to a characteristic Lower Cretaceous topography.

With the beginning of the Upper Cretaceous, the continent again sank into the sea, this time on a great scale except for Mexico. In this country the eastern half was entirely submerged, the central plateau only partly. As sedimentation went on as before, the new limestones and shales were deposited on the eroded Comanchean topography except in a few instances; and while these strata are not nearly as important as the Comanchean, they covered a great deal of the Gulf Coast and reached as far west as Coahuila, where the coal measures belong to this period. The Upper Cretaceous is the coal period in Mexico.

For us who are interested in the ore deposits of this country, special interest attaches to the latter part of this period; it marks a rapid succession of events in which enormous forces were at work in a dramatic way, with the result of making the mineral regions that we exploit today. The great volcanic eruptions, which we hold were primarily responsible for the beginnings of mineralization, began in the latter part of the Upper Cretaceous, they brought the period to a close, and continued on an enormous scale through the first part of the Tertiary, the Eocene period.

TERTIARY ERUPTIONS. It is now generally held that all ore deposits, except such as are obviously the work of sedimentation in shallow waters, like some iron deposits, have a close connection with igneous action, and that most ore deposits may be traced to the nearest intrusive volcanic rock-mass. It will follow that every geologic period is likely to have originated ore deposits

¹ Chamberlain and Salisbury, 'Geology', Vol. III, p. 143.

in connection with its own eruptive phenomena. Owing to the enormously superior importance in Mexico of the ore deposits that began in Cretaceous and Tertiary times, the varied steps, presumably more or less alike in different ages, that have given rise to ore deposits, will be described under the heading of the Tertiary period.

Until the close, then, of Cretaceous time, variously estimated at between 200,000 and 300,000 years ago, Mexico was almost entirely under the waters of the Gulf. The oscillation of level prior to that date sufficed to distinguish between the Lower Cretaceous, or Comanchean, laid down during the first submergence of the greater part of what is now Mexico, and the Upper, or true, Cretaceous laid down during the second or lesser submergence. Near the end of the latter, volcanic action broke out on a scale of such gigantic splendor, with consequences so far-reaching, as the earth had not seen since the Archeozoic era.

All along the Pacific axis, the pressure of huge masses of molten material beneath the existing surface began to push that surface out of shape in an easterly direction, folding and crumpling the sediments. Eastward folds lying today in the position into which they were squeezed, attest the force of the pressure. At the same time, more or less uniformly over the whole area, but perhaps a little more on the Pacific coast, a gentle and steady uplift began, part of a general elevation of the continent; this continued with few oscillations till the Gulf Coast had been raised some 5000 ft. above sea-level and the Central Plateau region between 5000 and 10,000 ft. For a perspective view of these events, it is only necessary to consider the Santiago River canyon in Jalisco, on the Tepic border, where lies spread out in a vast cut, more than 3000 ft. deep, the topography of Tertiary lavas through which the river cut its way while the whole country was being lifted bodily.

The agencies of land degradation being fully as active then as they are now, erosion and the carving out of topography proceeded rapidly, so that by the beginning of the Eocene, the first part of the Tertiary, the first truly modern period, the topography of this limestone plateau had been dissected deeply. With some changes, the distinction then made between the two coasts has been maintained; the Gulf Coast is sea-bottom that has been raised slowly to nearly its present position, whereas the Pacific Sierra region and the northern part of the Central Plateau are the much cut-down remains of the originally higher ground. In other words, until the beginning of the Tertiary, Mexico was a limestone country, uplifted from the sea-bottom, compressed in places into mountain-folds, carved by erosion into deep valleys and great mountain ranges.

Following these movements there have been renewed subsidences and elevations, which have left their records in the various sediments of the period; but for us, the events of first importance were the great volcanic eruptions, which changed our world in Mexico and were the beginning of the country as we see it today.

The irresistible swell of molten material from the

depths, which had been making itself felt along the Pacific axis in the folding of the strata, could no longer be contained, even by the thousands of feet of overlying sediments; the red-hot material, under enormous pressure, forced its way steadily through the lime, seeking and finding points of weakness scattered along the whole western coast line. With stupendous force, and pouring forth incalculable masses of melted rock stuff, the earth opened in thousands of vents. It is hardly possible for us to conceive the appearance of the Mexican plateau at this period. With thousands of volcanic openings in full or partial eruption, sometimes on dry land so that glowing lava-sheets crept over the surface, sometimes during a period of subsidence, so that the hissing ashes fell into the sea, the sight must have been unendurably grand, had there been human eyes to witness it. For a period that was geologically short, but that numbered many thousands of years nevertheless, these tremendous furnaces smoked and flamed, and rock by the thousands of square miles was poured out over the Cretaceous surface. In most places the molten masses filled the valleys that Nature had patiently carved out, and submerged the Cretaceous mountains in the sea of lava. The activity became less intense with distance from the Pacific axis, so that volcanic action was of less importance on the Gulf Coast; but on all the Mexico that was in the zone of eruption, that is, on all of present-day Mexico except small areas in the south, near the Gulf, and in Sonora, the effect was to bury out of sight the Cretaceous topography under thousands of feet of igneous rock, just as during the long Cretaceous sleep the effect had been to bury all the older formations beneath thousands of feet of limestone sediment. "The old order changeth, yielding place to new" was never more strikingly exemplified.

Most of Mexico was thus covered under a smoking mantle of hot mud, ash, and lava; the volcanoes subsided into fitful activity; a new era began in the making of topography. As the ground cooled, the forces that had sculptured hills and valleys and river systems during the Cretaceous now set to work on the igneous mass. This material varied considerably during the different eruptions. The earliest lavas were andesite, a rock of intermediate composition as regards the amount of silica present, that is, the so-called acidity; following these came rocks of more extreme type in both directions: rhyolites in the acidic or more silicious extreme and basalts in the basic or least silicious class. All these rocks are merely different phases of the same original material, and in crystallizing they followed recognized laws. Rocks of all three types were extruded in nearly every period; but in a general way it may be said that the andesites came first, the rhyolites next, and the basalts last. The most important andesitic masses made their appearance during the middle stage of the Tertiary (Miocene), being the green augite-andesite or hypersthene-andesite, which contains so many important ore deposits.

FORMATION OF LOBE-CHANNELS. The close of the

period of violent eruption was followed by spasmodic but slowly declining activity, continuing to the present day; the resultant cooling of the great igneous masses gave rise to a series of tension phenomena that were fundamental in originating the orebodies of the country, in that they produced the fractures in which those orebodies have been formed. The vast sheets of lava, some of them thousands of feet thick, began to cool and settle on their beds of limestone or ash; and besides the climatic or atmospheric influences that busied themselves in making the new topography, there began to take effect the forces of tension and compression on these rock-masses on a tremendous scale. As the rock cooled it slowly contracted, forming many intricate systems of fracture. As the fracture-blocks settled, other movements were set up, splitting them further, sometimes cutting across already existing cracks. Meantime, the occasional repetition of eruptive action pushed new masses of rock into the already disturbed ground, causing still further complexity of fracturing. The result of all this was to create throughout the region of vulcanism an infinite number of cracks in the earth's crust, of every conceivable shape, size, and direction. It is with these cracks, or the lines of weakness along the contacts of different kinds of rocks, and with the minerals that have formed in or on them, that we have to deal in studying the origin of ores. For it may be said roughly, but with confidence, that in order to have an ore deposit two things are necessary; first, fractures or other channels in which circulation of metal-bearing solutions can take place; and second, the metal-bearing solutions themselves. Not only were cooling-cracks in the intrusive rocks available as channels, but the sediments thus intruded, violently pushed out of place, were cracked on a great scale, the fractures naturally having direct communication with the eruptive mass; and the contact of the eruptive with the intruded rock, on account of difference in chemical composition, would always remain a line of weakness for ground-waters to follow.

MINERALIZATION. Perhaps the greatest controversies, and certainly the most inconclusive, in the study of ore deposits, have taken place over the manner in which these fractures are supposed to have become mineralized. As the science has progressed there have arisen successive schools of thought that have laid down dogmatically the manner in which ores have come into the veins where we find them, only to have their theories modified or disproved by later investigations. So much progress has been made in this work during the past ten years, principally along chemical lines, that much has been established that was formerly mere conjecture; and while much remains to be done, we are now in a position to outline the phenomena of ore-making with a considerable basis of proof and with little controversy as to fundamental principles.

A great obstacle to the progress of the science was removed when it was recognized that no one suggested agency was in itself sufficient to account for the conditions that we find in mineral veins, but that each of the

different processes put forward had its own particular virtue, which might well have been operative at the same time as any or all of the other agencies. Up to the point of formation of the fractures, the problem is largely mechanical, and there was no irreconcilable difference of opinion. Beyond that point each school claimed that some special process made the vein-filling. The lateral-secretionists insisted that the open fracture was slowly filled by the seepage of material through the walls, which crystallized in the opening, and gradually filled it; the material being derived from the wide circulation of ground-waters and the leaching of metallic salts. This was supplanted by the ascensionists with the theory that the waters came from great depths, where in some way they had access to mineral solutions. Finally, in our own day, investigators like Emmons, Lindgren, and Ransome have established the importance of the working-over of veins by descending metal-bearing solutions, and deposition from them on already existing metaliferous deposits. From this to the conception of ascending or circulating solutions effecting the same operation, of enriching an already existing deposit, was a natural and logical step. Finally, under the leadership of Vogt, Spurr, and Kemp, the importance of segregation from the magma, that is, of direct precipitation into place from the original rock-solution, has been universally recognized, and assigned to an important place among mineral-making agencies.

It will be observed that there is much truth in each of the theories advanced, and our thought today retains the essential kernel of truth in each of them. It was the tendency of early investigators to make a fetish of some one process, perhaps it is the tendency today; but at least we now recognize that all these agencies have their place and their use, and our knowledge is sounder for the admission. We now believe, on the basis of evidence broader and more scientific than what used to be accepted as such, that mineralization began to a certain extent when fracturing began; that every stage of disturbance and re-adjustment has had its accompanying stage of mineralization; and that the process was and is a purely chemical one, involving on the one hand the crystallization of metallic compounds out of watery solutions into a gathering place of some kind, and on the other hand, the dissolution and transportation of these metals from the original deposit to any other place to which the solutions may find their way. The principal point of dispute has remained the origin of the water that forms the solutions and carries the metals.⁵

The ideas of fifteen years ago as to the circulation of meteoric or surface waters to vast depths, with Van Hise as their leading and brilliant exponent, have not been confirmed by later developments in numerous deep mines. The theory, presented in the most convincing way, was that the waters performing the work of ore

⁵Van Hise, 'Some Principles Controlling the Deposition of Ores', *Trans. A. I. M. E.*, XXX, p. 27. Kemp, 'The Role of the Igneous Rocks in the Formation of Veins', *ibid.*, XXXI, p. 175; Spurr, 'Igneous Rocks and Their Segregation', *ibid.*, XXXIII, p. 238.

deposition come principally, if not altogether, from the surface precipitations of rain and snow; and that prolonged circulation to immense depths gives them the characteristics of heat and composition that are necessary for the work. The observations of Kemp, Rickard,* Finch, and others have shown that deep mines are nearly always dry when surface drainage is properly handled. The surficial waters, upon whose deep circulation such a complex theory of solution and re-deposition was built up, do not get down more than a few thousand feet.

Again, our most recent ideas on the origin of ore-

forward two fundamental conceptions as to origin, to which all phenomena may sooner or later be referred: first, as to the primary origin of the minerals found in orebodies; and second, as to the primary origin of the water that effected the work of transportation before deposition commenced and during the process. These concepts are the basis of the magmatic theory of the origin of orebodies, and it is believed that it fills the requirements reasonably. It has become widely accepted, and is the working hypothesis, at least, of many mining geologists.⁶

FIG. 2

bodies involved the conception, in some form, of general dissemination of the metals in minute traces through the earth's rock-masses; the metals being extracted by these deep-sunken waters, and carried into fractures to be deposited elsewhere. These ideas were based on wide experience and observation and were sound insofar as they referred to the shallow depths to which ground-waters circulate. The theory has been transferred bodily to the phenomena of secondary enrichment, in which it finds wide and important application. But the origin of the metallic masses which are attacked and dissolved by the circulating waters must be explained in a different way.

It seems to me that the work which has been done in economic geology during the past ten years has brought

THE MAGMATIC THEORY. For the purposes of this paper, the theory may be generalized as follows: the fused mass of rock-material in the depths of the globe, from the reservoirs of which all volcanic outpourings draw their lavas, is the magma, that is, the original rock-stuff from which all minerals are differentiated by more or less complex processes. This magma contains not only the minerals, as yet uncrystallized, which make up all classes of igneous rocks and all varieties of metallic minerals, but more important still, it carries abundant water and gas, in chemical combination with the other elements.

If we regard this magma as a solution, under pressure and high temperature, it is evident that any change of condition will cause immediate crystallization of some, at least, of the dissolved ingredients; and that the re-

*'Water in Veins—a Theory', E. & M. J., March 14, 1903, and 'Waters Meteoric and Magmatic', M. & S. P., June 27, 1908.

⁶Kemp, 'Theories of Ore Deposition', A. S. M. M., quoted in Mex. Min. Journal, Sept. 1915.

sult of such a crystallization will be not only the solid masses of rock or mineral that have been precipitated, but also the thin and watery solution remaining. In this solution, such ingredients as the rarer metals, that is, all metals except the iron-chromium group, will still be carried until favorable conditions induce precipitation. Any intrusion or outpouring of igneous rock, therefore, represents such a separation of the rock-making minerals out of an original solution, in which metallic and other minerals remain. In exactly the same way, possibly at the same time, the greater part of the iron or chromium minerals may separate out, gathering in a suitable place, and forming a magmatic segregation of these metals.

The magma, itself of intermediate composition, has a tendency to form the two extremes of acid and basic rocks, or, more accurately, the most silicious and least silicious rocks; the basic ones first, the acid ones last. Pure silica is the last substance to crystallize out; that is, a preferential separation of certain elements results as soon as crystallization begins at all. Now, it is an undisputed fact that the igneous rocks crystallize out from the magma; and there is general agreement that certain deposits of iron, chromium, and nickel are also crystallized directly from the magmatic solutions; and certain quartz-dikes carrying gold, as well as some platinum deposits, are believed to have originated in a similar way. General acceptance of the magmatic origin of the iron deposits came first after hard fighting; it has been followed by agreement as to many other deposits, as proof accumulated.

The next question is, what was the origin of the great bulk of deposits that have made profitable orebodies? The answer is difficult because of that word "profitable." If a deposit is not profitable it soon ceases to be exploited, and consequently our knowledge of it remains limited. On the other hand, we know that nearly every deposit that can be profitably worked, and many that cannot, have been gone over with minuteness inconceivable by later enriching, or leaching, solutions; that is, the original structures have been so altered and masked by later action that it is sometimes very difficult to find out what elements were first deposited, and what came later.

There are certain precious-metal deposits, like the Campo Morado lead-silver-gold mine in Guerrero,⁵ that we agree in imputing to primary deposition from metal-bearing solutions. Do such solutions owe their water to meteoric sources and their mineral to leachings from buried masses? Or are they in any way to be compared with the magmatic solutions from which the admitted nickel and iron solutions were thrown down?

Any mineral crystallization, in place as an ore deposit, may be regarded as a stage in a series of successive precipitations. The variety of minerals to be found there may be viewed as successive steps in the fractional precipitation of the various minerals from the mother liquor. Each one of the minerals has its own

degree of solubility, and so has each gangue-mineral. If in a solution resulting from the formation of igneous rocks there remain present silver, copper, iron, and other metals with silica and lime, then under certain conditions the silver might be thrown down first, followed by the copper, with the silica (as quartz) remaining to the last. Especially will precipitation occur in the presence of metals already deposited. A great deal has been done on this subject, in the laboratory, and much remains to be done; it is clear, however, that the question of precipitation must be mainly a matter of solubilities and chemical equilibrium.

The fact that gold is almost invariably associated with silica has been worked out in detail, and certain gold-quartz dikes have been shown to be magmatic segregations.⁶ If we extend the conception of the association of silica with gold, to include the other metals, excepting the iron-chromium group, then we have the type process as follows: the silicious metal-bearing solutions, remaining after the rock-minerals crystallize out of a magma, may find their way into a fracture or channel, under favorable conditions of heat and pressure, and encounter a precipitant. The various minerals present will come down in the order of their solubilities, generally speaking. The lead, let us say, will come down in crystals of galena, on the walls of the channel. Soon after, the silver will be precipitated, perhaps in combination with antimony or arsenic, the crystals resting on the earlier ones and building out toward the centre. Then, perhaps, the silica will increase sufficiently in strength to precipitate also, either in shapeless masses or as beautiful crystals resting on the others and nearly or quite filling the cavity. The process may be repeated several times if the channel is wide enough and the solutions repeat their entrance. The point to be emphasized is that the process is as purely a chemical one as the making of rock-candy from a sugar solution. The difference is that we make the sugar solution ourselves and then set all the conditions of temperature for precipitation; whereas we do not make the rock solutions and have no control over the conditions under which they work.

Such a condition of metal-carrying and of precipitation through differing solubilities exists whether the water that serves as a vehicle comes from the surface or from some other source; but it is obvious that if the rock-making minerals suddenly or slowly solidify out of a magmatic solution, we do not have to look for sources of water to effect all the operations discussed; the water is automatically there in quantity and with the metals already in solution.

We now see whence has arisen such a wide divergence of view between the opinions held by the school of Van Hise and those brought forward by Spurr and Kemp. The former conceive all ore deposits, exclusive of the admitted magmatic segregations first mentioned, to be due to deep circulation of meteoric waters, with mingling

⁵J. W. Finch, M. & S. P., Vol. 101, 1910, p. 496.

⁶Spurr, "Yukon Gold District", 18th Ann. Rept. U. S. G. S., Pt. III. Also Trans. A. I. M. E., XXXIII, p. 228.

of solutions of varying composition and resulting precipitation of minerals. The theory is sound as applied to shallow waters, but can only hold for the origin of most vein and contact deposits if it can be shown that meteoric waters can get down deep enough; or, if that cannot be shown, if it can be suggested that in some manner the mineral can be brought within the reach of these meteoric waters. The later investigators, by showing that the circulation of ground-waters of meteoric origin is restricted to a comparatively shallow zone, brought forward the present-day thought that the amount of water contained in igneous rocks when they are still molten is sufficient to serve as a vehicle for all the dissolved mineral matter that they bring up. This dissolved mineral matter must be precipitated somewhere, given favorable conditions; it is conceivable, and seems probable, that in some cases at least, precipitation of silver or lead minerals, for example, may have occurred out of such a solution due to lowering of temperature or pressure or both, such as might occur in the interior of a slowly cooling igneous mass. This would be a true magmatic segregation of the minerals mentioned; it would remain unchanged till later movements and the breaking-down of overlying rocks could bring the deposit within the reach of enriching solutions. But the limiting condition of such deposition, that it must take place within the interior of a great mass, uncontaminated by outside influences, makes it clear that such deposits can neither be numerous nor can they be easily brought within the reach of mining. Many igneous structures are lava-flows on an existing surface, hence immediately subject to cooling, to the formation of fractures, to deposition in these fractures from the solutions that have been described, and to immediate influence from oxidizing and meteoric agencies. By far the greater number of igneous structures that are not such flows are associated as intrusive masses with older rocks; and in these associations the contacts and the fracture in the intruded rock play the chief part in receiving mineralization. If a true magmatic silver deposit should be formed in the interior of the intrusive rock, with no communication with the outside, such a deposit will only be uncovered and come to our knowledge by an extraordinary combination of accidents. Before it is uncovered, later movements of the ground may allow circulating waters of meteoric origin to get in, to leach the deposit of some of its metals and carry them to some other point, or at once to enrich the magmatic deposit. Such may be the source of the metals in some ore deposits. In considering this, however, it would seem probable that the greater part of the thinner magmatic solution left after the rock-minerals form must find its way in great quantity and at once to the outside of the intrusive mass, there inevitably to be influenced by the physical conditions of the contact.

It seems logical to suppose, then, that true magmatic segregation of such metals as silver and copper may have taken place more or less as has been outlined; and that circulating waters of surface origin in the course of time reach some of these deposits, to leach and carry

away their metallic content. It is believed that, as research progresses, this will prove to be the case in an increasing number of instances. At the same time, it seems probable that the greater number of valuable ore deposits must have resulted either from the enrichment of such primary bodies by later mineral-bearing surface waters, or from the reaction of the magmatic solution proper with circulating meteoric waters or with other oxidizing conditions.

ENRICHMENT BY CIRCULATION. Primary ore deposits are merely a first concentration from an exceedingly dilute solution, speaking with reference to any particular metal. It is evident, therefore, that they will almost necessarily be very poor, economically speaking, and the instances are rare where such a first deposition of other than iron minerals has made a valuable ore deposit. The Campo Morado mine is the best example in Mexico, and it is a remarkable exception. The first deposition, as a rule, is simply a geological concentration of the metals, lacking a great deal of further concentration to give it economic value. We know little about such primary deposits, because the majority, not repaying exploration, are soon abandoned or are never worked at all. It takes the circulation of later waters, working for long periods of time, to effect this subsequent re-concentration. Such a later circulation can only take place when erosion or upward movement, long after, exposes the primary deposit to the influence of surface waters or to the atmosphere, when a new chapter is begun in the life-history of the deposit.

This phase of the subject, the gradual alteration of primary mineral into ore, or rock that it will pay to mine, has in the past decade been studied with great enthusiasm and success,² especially by American geologists. With the appearance of Posepny's paper and the ensuing discussion came a period of vigorous constructive thought on the subject, which had as its most important result the crystallization of the idea that it was not alone by ascending waters, nor by descending waters, nor by lateral secretion, that deposits of mineral are formed or modified, but by a combination of all of them, that is, by circulation of the ground-water. Waters, coming from intrusive masses and finding their way into channels in the rocks continue to move if they can. Such recently-formed (juvenile) waters are generally alkaline in reaction. Waters from the surface (meteoric), coming from rain or snow, soon become acid on sinking into the ground, due to picking up carbonic acid or traces of salts. We find that such acid waters, descending in veins, soon lose their acidity by contact with alkalis, either in the rocks or in the other solutions. The meeting and mingling of such acid and alkaline waters in the channels causes an interchange of burdens; the acid radicals react readily with the metals, the alkaline bases with the earths; the result is precipitation. Given a primary deposit containing

²"Enrichment of Sulphide Ores", W. F. Emmons, Bull. No. 529, U. S. G. S.

³T. A. Rickard, 'The Genesis of Ore Deposits', A. I. M. E., p. 219.

metals combined with sulphur in some form, which seems to be the usual form of primary deposition—there will occur precipitation on these sulphides if later solutions carrying the same or similar minerals come in contact with them under favorable conditions. If this is kept up for sufficient time, there is enrichment of the deposit. The process is unending. It began when Mexico was still a fiery furnace, early in the Tertiary, and it is going on today. The waters, both from magmatic sources and from the surface, take up their burden of dissolved material, and with all the infinite variety of combinations that result from varying pressure, temperature, class of wall-rock, openness of channel, and chemical composition, they go about their work of changing the nature of what they find. They dissolve valueless material from some deposits, leaving an oxidized mass, or 'gossan,' that perhaps is profitable: or they dissolve out valuable material, carry it to another place, and if they encounter right conditions they drop their burdens, enriching what already existed. This process, in its varying activities, as downward secondary enrichment, as upward secondary enrichment, or as enrichment by the circulation of metal-bearing surface-waters, has been shown to be the most important known agency in the working over of originally lean primary bodies till they are fit for exploitation. We learn from its study that today, when we find profitable ore, we find material which as a rule has not been deposited just as it is, but which is the result of complicated and long-drawn out re-concentration of originally poorer material.

To summarize: the primary deposit is a matter of great depth and of water derived from the great igneous masses, whereas the enrichment of such a primary deposit or its leaching for transportation to other places, is a matter of circulation in shallow depths of any waters that can reach it. To get this circulation, the primary deposit must be lifted to the surface face, or the surface must be cut down to it; if, through being covered by cap-rock or for some other reason, surficial agencies cannot affect it, enrichment, generally speaking, cannot occur.

Such in a general way has been the nature of the agencies that have formed orebodies. As soon as we begin detailed study, we find an infinite variety of special conditions, which have influenced deposition so that no two deposits are exactly alike in any respect, and nearly every one presents some feature peculiar to itself alone.

(To be continued)

In 1918, 15,445 tons of lead, valued at 13,193,100 francs, was exported from Tunis, almost exclusively to France; in 1917, foreign shipments of lead amounted to 18,713 tons, 15,794,785 francs in value, following the highest smelter production ever attained there. The average annual value for the period 1908-1917 of exports of lead was 3,638,000 francs, and the quantity, 4851 tons. A comparison of the 1917 and 1918 figures with these averages indicates the impetus of war conditions.

Mogollon District in New Mexico

*The Mogollon mining district has received little public attention, although for 15 years it has been the leading silver producer of New Mexico; it is situated in a region remote from the principal lines of travel, and its activities have usually been limited to the operations of two or three companies. The value of the total production of the district in the 44 years of its history has been estimated at \$15,000,000. For the years 1904 to 1917, inclusive, the output was: gold, \$4,370,000; silver, 10,042,000 oz.; copper, 874,862 lb.; total value, approximately \$10,500,000. In 1913 the district contributed 80% of the total silver production of New Mexico, but in 1917 only 41%, due to serious interruption in the operations of the leading producer. Since 1914 the silver output has diminished one-half, and the present high value of silver is nearly offset by the increase in cost of production. The output of gold has rarely exceeded 35% of the total for New Mexico. The ratio of silver to gold, by weight, has averaged 46:1 based on the whole output of the district. The town of Mogollon is 75 miles by a poorly located highway from the nearest railroad terminals, at Silver City and Tyrone. All supplies are transported by motor trucks and teams.

The area, sometimes called the Cooney mining district, lies on the western flank of the Mogollon mountains. The topography is rugged, the whole area being sharply dissected; deep canyons with steep gradients and rugged walls are characteristic of the whole western slope of the Mogollon range. The water resources in the neighborhood of the mineral area have been developed in a sporadic way; Mineral and Whitewater creeks have both furnished water-power at various times, but the extreme annual variation and the relatively small volume of the streams both necessitate large capital outlays for power development.

In 1875, J. Cooney noted the presence of copper-silver ore in the Mogollon mountains, and in the following year he and six others located and operated claims on Mineral creek. In April 1880, Victorio's band of Apaches raided the settlement and Cooney was killed. The village of Claremont was established on Cooper creek soon after Cooney's discovery, and the town of Cooney on Mineral creek soon became the centre of mining activity. The early production was confined to the shipment of rich copper ore which was found near the surface on Mineral creek. Prospecting resulted in the discovery of the silver veins to the south, and in the establishment of the town of Mogollon on Silver creek. These later discoveries led to the development of the most productive area of the district, and practically no attention has been paid to the older sections for 10 years. Improvements of metallurgical processes stimulated the development of the district, and after the introduction of the cyanide process at the Silver Creek mills, mining activity was at its height from 1905 to 1912.

*Abstract from a paper by D. B. Scott, New York meeting of the A. I. M. E.

Physical Examination of Hoisting Engineers in Utah

By C. A. ALLEN and DR. A. L. MURRAY

*In the spring of 1919, the Industrial Commission of Utah undertook the assembling of safety orders covering metal-mining operations. Just at that time there appeared several articles in the mining papers advocating the licensing of hoisting engineers, so this subject was given careful consideration.

The licensing of hoisting engineers means that they must pass an examination covering the mechanical features of hoists and boilers, and must have a certain amount of experience. This undoubtedly serves to get a class of men that are better informed about the mechanical operation and theoretical considerations in hoisting, and the only argument against it is that it is difficult to give an examination that will determine whether or not a man is competent to operate a hoist. A man might pass an excellent examination yet be absolutely unqualified for the actual work, and the judgment of the mine superintendent would have to be depended upon to choose the right man from among those who were licensed. This difficulty of properly determining, by ordinary examination, a man's qualifications to run a hoist caused the idea of licensing in the ordinary sense of the word to be abandoned; but, as there was no question that a hoisting engineer should be physically fit, it was decided to require a medical examination, and at the same time to require the hoisting engineer to state his experience, so that the State would have a better knowledge of his general qualifications.

The orders covering the question were therefore issued as follows:

Section 23. (a) Hoisting engineers shall be appointed by the superintendent, or by the master mechanic with his approval. They shall be men familiar with the details and working of hoisting-engines, shall be able to read and write English, and shall be not less than 18 years of age.

(b) Hoisting engineers, who hoist men, shall be not less than 21 years of age, and, before being allowed to operate a hoist on which 10 or more men are handled daily, the hoist-engineer must be examined by, and present a certificate of health from, a reputable doctor known to be such by the superintendent. This certificate of health must be on a form prescribed by the commission and must show the health of said hoisting engineer to be such that there is no danger of his becoming physically or mentally incapacitated while performing his duties or under the stress of excitement.

(c) All engineers now operating hoists, that handle 10 men or more daily, shall at once be examined and obtain such certificate in like manner, and all hoisting

engineers shall hereafter be examined in like manner at least once every year.

(d) It shall be the duty of the superintendent to permit no other than such duly appointed hoisting engineers to run such engine or hoisting machinery; except that, by and with the consent of the superintendent, specified apprentices may be taught the operation of the hoisting engine at such times and under such restrictions as the superintendent may determine to be free of risk to life and limb. Any superintendent failing to make such appointment of hoisting engineer, or knowingly appointing any hoisting engineer not qualified as above, shall be guilty of a violation of these orders.

(e) At every shaft in which 50 or more men are hoisted or lowered on any shift the commission may require that there be with the hoisting engineer, when the shift is being hoisted or lowered, an extra man sufficiently competent to operate the engine in case of an emergency.

It should be stated that previous to issuance, these orders were submitted to a committee of representative mine-operators and mine-employees and there were no objections raised except to the last paragraph. This paragraph originally made it compulsory to have another man beside the hoisting engineer, when the shift was being handled at the larger mines. The operators felt that this would not be necessary in all cases, so it was changed to be optional with the Industrial Commission as to whether it shall be required or not. The reason for exempting men handling less than ten men was largely one of expediency, but it was also felt that at small properties where few men are working the hoist is usually of slow speed and the engineer is under no particular strain.

After the orders were made effective by the Industrial Commission a form for examination was issued which is too detailed to reproduce here. In drafting this certificate two objects were considered: first, whether the applicant is mentally qualified, and, secondly, whether the physical condition of the applicant is such as to demonstrate his fitness for the work required of him.

The ability of a hoisting engineer to read and write English is practically the only requirement in the way of mental qualifications. He must be familiar with the safety orders of the Commission and of course must be able to interpret properly signals and rules which demand knowledge of English. His other mental qualifications are vitally important, but they can best be judged by the mine superintendent or master mechanic who is acquainted with him. The consideration of the applicant's experience is left also to the mine superintendent, although any man who had not had a reasonable amount of experience, depending upon the size of hoist he is to

*U. S. Bureau of Mines. Reports of Investigations.

operate, would be investigated by the Industrial Commission.

As to physical fitness, the requirements are that a hoisting engineer should be of general good health, alert, and possessed of his faculties of special sense, particularly good eyesight and good hearing. Although the position does not involve severe physical strain, yet a man laboring under certain physical defects may, at a critical time, be so handicapped by such defects that he cannot measure up to the strain placed upon him. Likewise a man who is suffering from some passive ailment such as a disease of the heart, lungs, kidneys, or nervous system would be liable during a period of unusual strain, as in time of a disaster, to suffer an acute attack and become a menace rather than an aid to rescue work. A man subject to fits, vertigo, fainting spells, or epilepsy should never be employed as a hoisting engineer. These conditions frequently result in sudden attacks, and if one occurred while the hoist was in motion the resultant danger to any men who might be on the cage at the time, is apparent.

Eighty-one applicants have filed reports of their physical examination. An analysis of the findings in these reports is given below.

Nationality

U. S. A.	53	Canada	1
England	12	Hawaii	1
Finland	5	Austria	1
Sweden	4	Italy	1
Norway	2	Servia	1

The above table shows that of the eighty-one applicants more than 65% were American born.

Ages

Under 25 years.....	4	45 to 55 years.....	20
25 to 35 years.....	27	Over 55 years.....	10
35 to 45 years.....	20		

Of those applying for positions as hoisting engineers 82% were between the ages of twenty-five and fifty-five years. The youngest applicant was twenty-two, and the eldest was sixty-six years of age.

Length of Experience

Less than 6 months.....	5	2 to 5 years.....	12
6 months to 1 year.....	8	5 to 10 years.....	17
1 to 2 years.....	9	More than 10 years.....	28

Two applicants failed to state definitely the length of time they had been engaged in hoisting-work. It will be noted that in all but thirteen instances the returns show that the applicants had experience covering more than one year.

The physical examinations show in most cases that the applicants were in good general physical condition. In two cases summary refusal of certificates was recommended. *Case I.* A man 61 years old, both eyes 20/50, right ear 50% normal, left ear 25% normal and exaggerated reflexes. *Case II.* A man 40 years of age, lost reflexes, suffering from occasional vertigo and presenting a history of syphilis.

In several cases where the eyesight of the applicant was defective but capable of correction by properly fitted

glasses, and in a case of hernia where no statement was made as to the wearing a truss, action was held in abeyance until a report showing that these defects had been corrected.

Twenty cases of defective vision ranging from 20/30 to 20/100 without glasses were shown. Most of these cases were very slight and all were corrected by glasses except three. *Case I.* Right eye 20/20, left 20/100. A letter was written to the applicant suggesting the advisability of having his eyes examined and glasses fitted, and requesting a report of the optometrist as to the results obtained. The report of the optometrist showed a correction in the case of the left eye to 20/50. *Case II.* Both eyes 20/60. A letter was written as above. The report of the optometrist showed a correction to 20/30 with the possibility of return to normal after wearing glasses. *Case III.* Both eyes 20/70. A letter was written as above, but as yet no reply has been received.

Four cases of minor defects of limbs resulting from old fractures were reported, but in no instance was the deformity of sufficient consequence to debar the applicant from the position he sought.

Three cases of hernia were reported, in two of which the applicants were fitted with trusses. The other failed to state if a truss was worn and a letter was forwarded seeking this information. As yet no reply to this letter has been received.

On qualifying for the physical examination, hoisting engineers are provided with a card-certificate entitling them to practice their trade.

As far as has been determined there has been no objection raised to the examination by the men themselves. Those who have expressed themselves to the inspectors of the commission have been favorable toward it. It is well recognized in the mining industry that hoisting engineers, as a class, are men of good judgment, are fair-minded and dependable, and it seems that the engineers of Utah have taken the attitude that could be expected of reasonable men.

In reference to the re-examination of the men yearly, the analysis of the results of the first examination shows that many of the men will be physically fit for a good many years, while others, who have a tendency toward some weakness, should be examined yearly. It may be found advisable to allow the examining physician to exercise some discretion as to the completeness of the re-examination, having before him the results of the examination of the previous year.

According to G. L. Logan, Consul at Penang, Straits Settlements, the success of the American dredges now operating in the tin fields of the Malay Peninsula has given marked impetus to the use of such machinery, which is further assisted by the scarcity and increased wages of the Chinese coolies by whose hand-labor tin recovery has been accomplished heretofore. Dredges not only work the virgin fields cheaper but even have been found to work profitably in ground already worked over by primitive methods.

Two Famous Letters From Mr. Hoover

The first is the letter written to Mr. Condict on the occasion of President Wilson's partisan appeal on the eve of the Congressional elections in 1918. The second is his letter to Mr. Arnold, the chairman of a committee at Los Angeles that wanted to work in behalf of his nomination to the Presidency. Our readers will be glad to have the full text of these important statements.

November 2, 1918.

Frederick R. Condict, Esq.,

134 East 56th Street, New York City.

My dear Friend:

I have yours of November 2nd in front of me.

My own views are summarized in a word; that we must have united support to the President. In the issues before us there can be no party policies. It is vital that we have a solid front and a sustained leadership.

I am for President Wilson's leadership not only in the conduct of the War but also in the negotiation of peace, and afterwards in the direction of America's burden in the rehabilitation of the world. Our object in this war is to see the establishment of governments in the Central Empires that are responsible to their people. This is the vital safeguard to permanent peace. The passing of their militaristic autocracies must be and is rapidly being marked by such treatment as to put that system out of action forever.

There is no greater monument to any man's genius than the conduct of negotiations with the enemy by the President. There has been a steady growth of realization by the German people and her deluded Allies of the debauchery into which they and the world have been plunged by militarism. The President has by his conduct and word stimulated this realization. He has assured them justice if they themselves will throw off their yoke and he has not hesitated in application of our every resource in force against their military dictators.

If the final overthrow and surrender of autocracy can be accomplished through the German and their allied peoples themselves, the President will not only save the lives of a million American boys and countless innocent women and children, but will have attained more complete victory and a more permanent guarantee of peace than any other means. The President's leadership has gained gigantic strides in this course. The terms of surrender are being made by Marshal Foch and our military leaders. The action of the Bulgarian, Turkish, and Austrian people has or is forcing the acceptance of these terms. The German people will sooner or later do so.

Our objects in the overthrow of all autocracies in Europe and the establishment of government by the people is but part of our great burden for beyond this, when these immediate objects are attained, we still have before us the greatest problem that our government has ever faced if we are to prevent Europe's immolation in a conflagration of anarchy such as Russia is plunged in today.

We must nurse Europe back to industry and self-support and we must ourselves avoid entanglement in the process. This can be accomplished only by this same leadership which has the confidence of the great mass of people in Europe. The President has spoken throughout this war the aspirations of the vast majority of the American people. There is no other leadership possible now if we are to succeed in these great issues.

Yours faithfully

HOMER HOOVER.

March 8, 1920.

Mr. Ralph Arnold,

Engineers Club, New York City.

My dear Arnold:

I have given deep consideration to the urgent recommendations of the Committee of which you are chairman. Such proposals are indeed a great honor, but I feel that I cannot alter the attitude that I have consistently preserved in these matters. It is, however, due to old friends that I should make this position perfectly clear to you and your colleagues.

First, I am an independent progressive in the issues before us today. I think that at this time the issues before the country transcend partisanship. It is well known that I was a Progressive Republican before the war and, I think rightly, a non-partisan during my war service. The issues confronting us are new and the alignment upon them has not yet been made by the great parties. I still object as much to the reactionary group in the Republican party as I do to the radical group in the Democratic party.

Second, I am not seeking public office and consulting my own personal inclination I do not want public office. I cannot prevent any citizen or group of citizens from agitating that I should take public office, but I cannot conscientiously participate in any organization to that end. I belong to a group which thinks that the American people should select their own officials at their own initiative and volition, and that resent the manufacture of officials by machine methods. I feel sure that if I entered the race for nomination to the Presidency, and undertook to solicit and spend the cost of propaganda and organization, this would be in itself a negation of the right American instinct, because of the obligations that it all implies. I thoroughly believe that I, like any other citizen, should always be ready for service when really called upon, but to go out and try to persuade the public to call me is opposed to my every instinct.

Third, I hope to have the affection of my countrymen, but my ambition is to remain a common citizen, ready to engage in team play with any organization and leadership that has for its objective the consummation and maintenance of great issues in the forms that I believe are to the public interest and benefit. I of course believe in party organization but it must be for the promotion of issues, not of men. I am not a straddler on any issue. I spend most of my time agitating for issues that I believe in. It is the privilege of all of us to hold our own views and it is our duty to express them when called upon to do

so. But no man can be so arrogant as to assume that he can dictate the issues to the American people or to the great parties they support.

Fourth, you and your friends have urged that I should undertake to organize propaganda for myself, as representing issues, by entering into competition for nomination by a great party. Aside from the reasons mentioned above, this implies entry upon a road of self-seeking, whereas my view is that I should agitate for the issues, not for myself. You rightly say that joining sheer organization without issues is simply office hunting without regard to public service.

Finally, I am not so ignorant as not to realize perfectly well that such a course does not lead to nomination to the Presidency, but I would not be myself if I started out on a path of self-seeking to obtain any office.

Yours faithfully

HERBERT HOOVER.

Italian Quicksilver Industry

Monte Amiata, situated in the Grosseto-Siena region, is the centre of the Italian quicksilver industry, and the output from this region represents approximately the entire national production. The ore-producing zone stretches for 40 kilometres (1 kilometre = 0.62 mile) in a direction parallel to the Apennines, and covers an area of 400 square kilometres. The entire region is mineralized, but only special pockets are sufficiently rich to repay the cost of working. There are at present eight active mines. Three mines have lately been worked out and abandoned, but have been replaced by bringing in two new ones.

The most important of the mineral deposits about the Monte Amiata region is red sulphide or cinnabar. Sometimes, but very rarely, the liquid metal is found in the form of minute drops. The wealth of the deposits does not increase with the depth of the mine, but exhausts itself at about 600 ft. The relative superficiality of cinnabar deposits is characteristic of mercury mining the world over. It is an advantage so far as prospecting and operation are concerned, but a drawback in that it shortens the life of the mines, which are exhausted as soon as the bed has been completely mined.

The future of the Monte Amiata region lies in the extension, rather than in the increased depth, of the producing zone. Experts estimate that the region will continue to supply ore in undiminished quantity for several centuries to come. This, however, is dependent upon the discovery and exploitation of new beds. Under present conditions of abnormally high fuel and labor costs, only the richest deposits are being worked at a profit. Cheaper processes of production may be devised that will render available vast deposits of low-grade ore that are not workable at present.

The high cost of fuel is the heaviest item of expense in ore reduction. The ore is always treated on the spot, being first dried in the sun on platforms or in artificial desiccators. The old type of distilling retort ovens have

been given up; they were dangerous because of their mercurial fumes, and uneconomical because of waste. Two types of ovens are now in use—one for the treatment of large fragments of ore, which are mixed with charcoal in simple tank ovens, and special drop or rotating ovens for treating the smaller fragments of ore. Both these types minimize dispersion, but require great quantities of fuel. In addition, enormous quantities of timber are used as mine props for sustaining the 'galleries'. The double call on timber for charcoal and mine props has made a devastating inroad on the scanty forest resources of the surrounding country. It is now proposed to avoid this excessive use of wood by the installation of electric ovens for ore reduction. Water power from the Apennines is available for hydro-electric energy, but electric smelting has not come up to the high expectations of its proponents.

In the course of investigations recently made of the new electric-smelting operations of the Ansaldo company at Cogne, in the north-western corner of Italy, it was found that the estimated cost of hydro-electric energy in the form of continuous current working 24 hours per day and 365 days in the year, must be held down to \$9 per horse-power year to assure commercial success to electric smelting. Before the War the cheapest hydro-electric plant in the world was at Trondhjem, Norway, with an annual horse-power cost of \$6. In Italy, hydro-electric undertakings rarely run under \$100 per horse-power for installation, which gives an interest charge of \$6 to start with; adding to this \$2 for amortization and \$3 for overhead, we get \$11 as the cost per horse-power year. Two minor difficulties add materially to production costs in the Monte Amiata region: (1) The emanations of sulphureted hydrogen, necessitating the extensive use of electric ventilators; (2) the character of the soil—occasional strata of loose soil are encountered, which become saturated with water and cause the galleries to cave in.

As to fuel, native wood and wood charcoal are used, imported coal not being obtainable. The furnaces treat from 14 to 15 tons of ore per day, at a consumption of one quintal (220 lb.) of wood per ton of mineral treated. The above consumption estimate does not include the fuel used for drying the ore, which varies according to the dampness of the latter.

The production of mercury (in tons) in the Monte Amiata (Grosseto-Siena) districts, was as follows in the years 1915-1918: Ore—1915, 110,612; 1916, 132,524; 1917, 113,782; metal—1915, 985; 1916, 1093; 1917, 1071; 1918, 1038. Total production of Tuscan and Idrian mercury in 1918, was: Monte Amiata (Grosseto-Siena) districts, 1038 tons; Idria (estimate of the Italian Bureau of Mines), 600 tons; total, 1638 tons.—U. S. Commerce Reports.

For the advancement of engineering knowledge and practice, the maintenance of high professional standards, and the fostering of a spirit of co-operation a new society, called the Association of Chinese and American Engineers, has been formed in Peking. The provisional constitution was signed by 39 engineers.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

FEBRUARY OUTPUT FROM CRIPPLE CREEK.

CRIPPLE CREEK.—The gold mines of the Cripple Creek district during February, as shown by the reports of the treatment plants, produced 40,541 tons of ore with an average value of \$12.61 per ton, and gross bullion value of \$511,501. The mills handled all but 700 tons of high-grade ore that was shipped direct to the Pueblo smelter of the American Smelting & Refining Co., with an average value of \$75 per ton and bullion value of \$52,500.

The Golden Cycle mill at Colorado Springs reported treatment of 21,000 tons of \$20 ore, with a value of \$420,000 and the Portland Gold Mining Co.'s Independence mill, near Victor, treated 18,841 tons of ore with gold value of \$2.07 per ton. The Golden Cycle M. & R. Co. paid its regular monthly dividend of three cents per share amounting to \$45,000. Miners in the district are now working under either a contract or bonus system and are making high wages, but a shortage still exists of competent miners. So acute is the shortage that in the City of Victor mail carrier service has been discontinued, because of the departure of many miners and their families from the district.

The Portland company reports in sight at the 23rd level of the No. 2 shaft, on Battle mountain, sufficient ore to keep the present force engaged for the next two years. The drift has been extended 500 ft. on the 23rd level, 180 ft. below the Roosevelt tunnel level at 2131 ft., 400 ft. of the drift has been in high-grade ore and the breast is still in the ore-shoot. Pumps easily are handling the flow of some 300 gallons per minute. Sinking will soon be resumed and a 200-ft. lift of the 500 ft. proposed will mean undertaken when the work starts.

LEADVILLE.—The Leadville District mill, one of the oldest in Lake county, operated last year by the Colorado Concentrating Co., has been taken over for a long lease by the American Smelting & Refining Co. The plant will be remodeled and re-equipped for experimental tests on Lake County low-grade complex ores, to determine the best adapted process. A large tonnage of low-grade ore can be furnished from the Yak tunnel and other properties in the district. The mill was erected in the early 'eighties to treat iron-pyrite containing lead-silver minerals. It was later remodeled for treatment of mixed lead-zinc-iron ores and has been under many managements in the past thirty years. Recently the plant was re-designed by the Colorado Concentrating Co. Success of the experimental plant will mean much to the district.

After the determination of the process to be used, a plant of large capacity will be constructed by the A. S. & R. Company.

MICHIGAN

QUINCY.—COPPER RANGE.—VICTORIA.

HOGGINGTON.—Few companies are doing more for their men, in the way of welfare work, than is the Quincy. Various Christmas celebrations were arranged for the families; the club-house is patronized by the men in large numbers; the library has developed during the year and is used by the men and their families. In accord with the general plan for improving the living conditions, extensions of the sewer system to the homes of employees have been completed. Last year 1000 ft. of main sewers was laid completing a plan of 5700 ft., with 3000 ft. of connections to individual residences. The homes are commodious. The garden space with each home is large and the men are encouraged to plant gardens. The last lot of 50 houses built by the Quincy company was quickly occupied by the men. An improved water supply for the homes was secured by means of drills in the upper levels of No. 9 shaft.

Production of silver from the Quincy continues to be an important item and it is given more importance because of the present high price received. The Quincy at this time is averaging better than 1500 oz. of silver per month. The record for 1919 will be better than 15,000 oz., according to reliable estimates, while the output in 1920 will run close to 20,000 ounces.

Production of copper from the three mines of the Copper Range company, Champion, Baltic, and Trimountain, shows a material falling off in February as compared with January. This is due to two important factors: illness among the underground employees, and the shorter month. On the other hand, in each case there is a slight betterment in the grade of ore secured so that the refined output will not be so much lower. The production in 'rock', compared with the production in January, follows:

	February, tons	January, tons
Champion	38,000	49,000
Baltic	14,000	15,000
Trimountain	12,000	14,500

Like all the other companies of the district the Mohawk output for February will show a falling off when the final figures are in. The tonnage of 'rock' was 39,879 compared with 46,629. There is every reason for the belief that the material will grade up to 22 lb., but the month's

output will be below 1,000,000 lb. Mohawk has not been troubled so much by the influenza epidemic as the other mines. It is rumored that the Mohawk has not kept its development openings sufficiently advanced. This is a mistaken impression. There are today openings for two years work in the Mohawk mine, all of them in a grade of material which will run better than 20 lb. per ton.

Victoria produced 170,000 lb. of crude copper during February, from which was secured 114,000 lb. of refined. This mine, like many of the other mines, suffered in the depletion of its working forces during the month owing to the general epidemic of sickness. At the present time Victoria is working 24 drilling-machines and this number could be doubled if more men could be secured. There is hope for the betterment in the situation at Victoria with the coming of spring. The long severe winter is hard on the people living in an isolated mining locality, but the summers are fine in Ontonagon county and the Victoria location is one of the beauty spots of the State. No further opening has been made at the 28th level. The cross-cut into the lode was 30 ft. and the faces indicate ore. The general run of the drifts to the south of the shaft are in a grade of material which is up to standard.

NEVADA

FLUORSPAR COMPANY OPERATES AT BEATTY.—DIVIDE NOTES.

BEATTY.—The Continental Fluorspar Co., a Delaware corporation, in the course of development work on claims in the Bare mountains, 5 miles south-east of Beatty, has shipped 14 carloads of material containing 90% calcium fluoride. Fluoride is used in blast-furnaces in the manufacture of steel, by glass factories, for the recovery of potash in cement plants, and for making hydro-fluoric acid for use in the manufacture of ceramic products. The purple spar is used as a pigment in making paint. During the past year the Continental company has employed an average of 25 men. The deposits are in fissure veins and on one claim, the Daisy, there is an outcrop 200 ft. long. On this claim a 6 by 8-ft. inclined shaft has been sunk 160 ft. in solid fluorspar. On the 85-ft. level two drifts, each over 100 ft. long, have been driven in fluorspar. At this depth the vein is 17 ft. wide. One-half mile west from this claim is another, the Fluoride, in which the company has sunk a 70-ft. shaft in material containing 92% calcium fluoride with a low silica content. It is thought further work may prove this vein to be a continuation of that in the Daisy. Four miles south is another group of claims in which there is a vein 150 ft. wide, with the outcrop visible for one-half mile. Little work has been done in this group, which contains commercial material. The company has erected at Beatty a plant for grinding the product to 150 mesh with a Sturtevant mill. Power is furnished by a Venn-Severin semi-Diesel engine using 27 oil. A 15-hp. Fairbanks-Morse hoist is used at the Daisy shaft and the ore is dumped directly into bins, from which trucks take it to the mill. No stoping has been done in any of the claims. The deposits are said to be unique in being free from sulphides. It is said that all other deposits contain lead, zinc, copper,

or other minerals in sulphide form, the fluorspar being secured as a by-product of concentration.

GOLDFIELD.—The funds raised by the Yellow Tiger through the assessment levied recently are to be used in further development of a silver mine near Stonewall mountain, 14 miles south of Goldfield, and none of the money, except that already spent in surface prospecting, is to be used in the Goldfield district. The mine at Stonewall has been worked for many years by Gordon M. Bettes, secretary for the Yellow Tiger company, and according to him, there is exposed 9000 tons of ore of an average value of \$21 per ton. He says: "There is in sight at least \$200,000 in recoverable ore." It is proposed to drive a 1600-ft. tunnel to cut the main vein at a depth of 1200 ft. The claims, a group of six, have been optioned by the Yellow Tiger for a stock consideration. Whatever the result of this venture, mining men consider that the chances for success are better than if the funds from the assessment were to be spent on the claims of the company at Goldfield. Development company stockholders are responding well to the call for a 3-cent assessment, according to officials of the company, who say they expect over \$85,000 to be realized. The levying of the assessment, coming at a time when official statements indicated milling on a good scale would be started soon, came as a surprise. A cross-cut on the 300-ft. level of the Silver Pick has been driven 55 ft. into the Mohawk vein in leased territory and indications are that the work is being done in an ore-shoot of medium grade. Assays of from \$7 to \$250 are being secured and it may develop that a find of more than ordinary importance has been made. The ore is in a previously unexplored part of the vein 300 ft. long and much additional work will be necessary before the value of the shoot can be determined.

DIVIDE.—Recent developments connected with the discovery of ore on the 500-ft. level of the Gold Zone and on the fifth level of the Tonopah Divide indicate that the orebody in the latter dips to the south-east. This has been a subject of discussion among engineers since rich ore was first found on the third level of the Tonopah Divide, as a dip in this direction would bring the orebody well into the Zone at a depth of from 700 to 800 ft. The south-east drift on the fifth level of the Tonopah Divide is reported to be in 35-oz. ore at a point 375 ft. from the cross-cut from the shaft, which, in connection with the position of the south-eastern ore-shoot on the upper levels, indicates a decided dip. The Gold Zone management plans to continue to a depth of from 150 to 200 ft., a winze being sunk in the newly found ore, and if conditions continue favorable the shaft will be sunk to 700 ft. The vein is 20 ft. wide and it is reported that the average value of the ore for this width is over \$15. Control of the Harrell, adjoining the Tonopah Divide, Gold Zone, and Alto, is reported to have been sold in New York. It is planned to deepen the 65-ft. shaft, and the company is negotiating to take over several prospects in outside districts. Among the developed prospects being considered is the Whitaker-Moon group in Montezuma, in which a promising lead-silver orebody has been developed. The new vein in the Alto has widened to from 18 in. to 1 ft. and assays of as

high as \$45 have been secured from this width. The ore is a sulphide.

MANHATTAN.—The cross-cut being driven on the 800 ft., or bottom level, of the White Caps, is expected to enter the vein in April at a point 400 ft. from the shaft. There is reported to be a good demand for the arsenic being mined on the sixth level and the ore is being shipped through Tonopah. The ore is practically solid orpiment and realgar and the company receives for it \$32 per ton, f.o.b. Tonopah. It is planned to construct a flotation plant as an addition to the mill.

PIONEER.—The Mayflower has been closed because of the impossibility of securing an ample water supply for

owners continue confident that the payment will be made.

CACTUS. Eight men are employed in constructing buildings at the Cactus Nevada and in extending the north drift on the 160 ft. level. A contract has been let for sinking the shaft an additional 100 feet.

UTAH

UTAH CHAPTER OF AMERICAN MINING CONGRESS ELECTS OFFICERS.

SALT LAKE CITY. The Utah chapter of the American Mining Congress held its annual meeting March 8, and elected officers and directors for the ensuing year. A. G. Mackenzie, secretary and treasurer of the chapter, made

JANNEY FLOTATION MACHINES IN THE ARTHUR PLANT OF THE UTAH COPPER CO., AT GARFIELD, UTAH

the mill from the present source, a spring near the mine, according to J. B. Kendall, manager. A second reason for closing, according to Mr. Kendall, is that the oil used to drive the machinery at the mine and mill no longer can be secured and gasoline is too expensive. It is proposed to make changes in the plant that will permit the use of cheap fuel-oil and Mr. Kendall says the water-supply problem can be solved by using another source. The shaft of the Reorganized Pioneer is 560 ft. deep, or 110 more than when sinking was resumed. In a statement accompanying notice of assessment No. 2, W. J. Tobin, president, states that the \$15,000 indebtedness of the company has been liquidated. Since March 1 of last year 175 ft. of lateral work has been done.

TULE CANYON.—The holders of the option on the Ingalls mine have been granted a short additional time for making the first payment, which was due March 12. The

his annual report and some routine business was handled. At the membership meeting the following board was re-elected: Walter Fitch, H. M. Hartmann, Frank J. Westcott, C. E. Loose, Norman W. Haire, and J. B. Whittehill. The new members of the board are Samuel K. Kellock and J. M. Bidwell. After the membership meeting the directors met and elected George W. Lambourne, governor, to succeed Inner Pett.

PARK CITY.—The Judge Mining & Smelting Co. and the Daly West Mining Co. have declared dividends. The Judge company will pay on April 1, to stock of record on March 20, a dividend aggregating \$60,000, at the rate of 12½¢ per share. Daly West will pay on April 1, to stock of record on March 20, a dividend aggregating \$37,500, at the rate of 15¢ per share. The dividend to be paid by the Judge Mining & Smelting Co. is the first declared since April of last year; the one to be paid by Daly West

is the first to be paid in seven years. One orebody above the Judge 1200-ft. level has produced during the last two months on an average of \$1000 per day, with the value of the ore above \$100 per ton.

Shipments from the mines for the week ended February 27 totaled 2310 tons, a slight decrease from the output of the previous week, when shipments totaled 2400 tons. Ontario shipped 825 tons; Judge, 614 tons; Silver King Coalition, 493 tons; Daly West, 218 tons; Daly, 105 tons; and Naildriver, 55 tons.

The annual report of the Silver King Coalition Mines Co. shows there was mined during the year 1919 a total of 19,462 tons of ore, or a gross yield to the company of \$1,088,513 and to lessees \$6611. The contents included 528,328 oz. of silver, 14,587 oz. of gold, 10,862,687 lb. of lead, and 145,716 lb. of copper. From the gross yield deductions were made of \$521,214, cost of extraction; \$241,300, cost of reduction; \$63,599, for transportation; and \$6905, for construction work at the mine. It is estimated that the total assessed valuation of this property will be well over \$1,000,000.

EUREKA.—Nineteen mines in this district shipped 138 cars of ore during the week ended February 27, as compared with a total of 158 earloads for the preceding week. The Chief Consolidated had an output of 31 cars; Dragon Consolidated, 21 cars; Iron Blossom, 16 cars; Tintic Standard, 15; Grand Central, 11 cars; Eagle and Blue Bell, 8 cars; Centennial Eureka, 7 cars; Colorado Consolidated, 6 cars; Gemini, 5 cars; Mammoth, 4 cars; Bulion Beek, 3 cars; Victoria, 2 cars; Alaska, 2 cars; Swansea Consolidated, 2 cars; Gold Chain, 1 car; Ridge and Valley, 1 car; Empire Mines, 1 car; Rabbit's Foot, 1 car; Sunbeam, 1 car.

Since work was started through the Yankee shaft for the development of the May Day ground, at a depth of 1800 ft., a total of approximately 600 ft. of drifting has been done, and further work will be carried forward as rapidly as possible. Some fairly good ground has already been prospected in this section of the May Day territory. The new Tintic-Davis company is planning the erection of new machinery and other improvements. Arrangements have been made for an extension of the power line to the property and it is expected by early spring to be busy with the sinking of the main working shaft. Already a force of men is at work preparing for the machinery and teams are busy hauling the new equipment. Meetings were held at Provo, on March 11, by a number of mining companies controlled by the Knight and Loose interests. The Grand Central company declared a dividend of 4c. per share, which totals \$24,000, payable March 22. This brings the total dividends paid by this company to \$1,862,000.

ALTA.—The gross output of the Sells Mining Co. of Alta for 1919 was \$10,940, and the total expenses were \$35 080, leaving a net deficit of \$24,140. Alta Consolidated stockholders have received notice of a special meeting of the company to be held on March 22 for the purpose of considering and voting on the question of increasing the capital stock of the company from 600,000 to

1,000,000 shares. During the year 1919 the company's development consisted of 935 ft. of drifting, 380 ft. of raises, and 170 ft. of sinking. The installation by the Little Cottonwood Transportation Co. of a spur to connect with the bins at Tanner's flat is expected to considerably reduce the cost of transportation.

WISCONSIN

REVIEW OF FEBRUARY.

Firm prices for zinc ore, all grades, and lead ore higher in price than at any time in a year or more, failed to afford much incentive toward increased production during the month of February, in the Wisconsin field. The chief drawback was found in the labor situation. An acute scarcity of shovelers was complained of by all leading operators and diligent effort to supply the deficiency failed to secure relief. Coupled with this was a season of cold weather and heavy snows, and roads were in such abominable condition that supplies and ore moved with great difficulty. Producers removed from railroads were at times completely isolated. Open market quotations at the beginning of the month, ruled on a base of \$51 per ton. This level was advanced about mid-month, prime Western blende holding on a base of \$51 per ton, and premium-grade blende at \$54 per ton.

Lead-ore sellers held a distinct advantage all month, on account of a steady demand for ore at high prices. Offerings ruled steadily the first half of the month at \$100 per ton, or better. Toward the middle of the month offerings advanced to \$102.50 per ton, 80% metallic content. The last week in the month found the base held at \$105 per ton, with few producers showing a disposition to market. Production was rather under normal as the complete output of mill-feed for the month fell off considerably and with this went in relative proportion the recovery of lead ore, since most of the lead ore produced in the Wisconsin field is obtained as milling by-product. Should high prices for lead ore continue no doubt many small mining concerns will be engaged in mining lead the coming spring. The break-up is near at hand and the offerings for ore are a strong incentive toward an increased production.

Producers of carbonate zinc ore were confined to the mines of the New Jersey Zinc Co., in the Highland district, and these were not regular in their deliveries. The prices offered made a gain to \$40 for 40% zinc. Deliveries of zinc ore, from mines to reduction-plants in the field, and from mine to smelter direct, and lead ore, were made for February, by districts, as here given:

District	Zinc, lb.	Lead, lb.
Benton	8,478,000	478,000
Livingston	4,832,000	80,000
Galena	3,752,000	30,000
Cuba City	1,594,000	244,000
Hazel Green	1,214,000	140,000
Linden	580,000
Highland	480,000
Platteville	176,000
Shullsburg	76,000	554,000
Total	21,182,000	1,526,000

Shipments of high-grade blende to the smelter were made for February as follows:

Company	Blende, lb.
Mineral Point Zinc Co.	1,190,000
National Zinc Ore Separators	2,720,000
Wisconsin Zinc Co.	2,686,000
Block-House Mining Co.	176,000
Linden Zinc Ore Co.	174,000
Total	10,246,000

BRITISH COLUMBIA

DEVELOPMENT NEAR NEW HAZELTON.

VICTORIA.—The Provincial Minister of Mines has been in conference with the president of the Canadian Pacific company with the object of reaching some arrangement with the railway official by which a large tract of land on Vancouver Island may be thrown open for mineral location. This tract was given to the railway company as a consideration for building the Esquimalt and Nanaimo railway, the gold and silver rights being reserved. As practically any gold and silver that occurs over this area, so far as is known, is associated with base metals, under present conditions it offers no inducement to prospectors, and, as the company is not exploring the land, a large area of promising mineral land has been tied up. It is to be hoped that the Government and the company may be able to reach some satisfactory arrangement by which the land may be thrown open for location.

VANCOUVER.—It is reported that the Lucky Four, at the head of Wahleach creek, in the New Westminster division, has been bonded to the Guggenheim interests. A large body of low-grade copper ore occurs in a zone of altered sedimentary rock. The property comprises 12 mining claims.

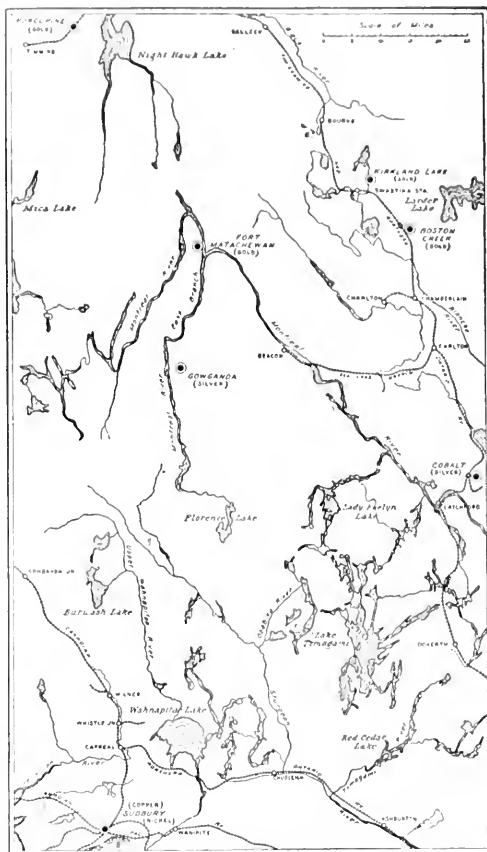

ANVIX.—It is rumored that the Granby Consolidated M. S. & P. Co. will build a large concentrating mill at its Hidden Creek mines, to treat ore that is too low grade for direct smelting. There is said to be a reserve of 10,000,000 tons of this class of ore, and, during the past year, the company has been experimenting with it in a 100-ton plant, erected for the purpose.

NEW HAZELTON.—On Hudson's Bay mountain there are a number of promising properties under development. The Mamie, under bond to Seattle capitalists, is attracting attention. J. D. Galloway, district engineer, reporting in 1917, said of this property that the ore-minerals disseminated through the gangue in bunches and stringers are zinc-blende and arseno-pyrite, together with a little chalcopyrite. The main metal in the ore is zinc, but the arseno-pyrite carries some gold. Some silver occurs with the zinc, but as a rule the silver content is low. The Victory and Empire groups, staked by the Simpson brothers, are under bond to the Skeena Milling & Mining Co., which has started building a concentrator. There is the Coronado group, also leased by the last named company, which is showing up well. It is considered one of the most promising properties on the mountain.

ROSSLAND.—The strike of the metal miners here is at an end. It lasted two days, being called as a result of

the company's decision to cease shipment of ore to the Trail smelter pending certain development work. The men decided to return after a conference with officials of the company.

TRAIL.—Ore receipts at the Trail smelter, Consolidated Mining & Smelting Co., totaled 5692 tons for the week February 15 to 21. Up to the latter date the smelter has received this year 53,534 tons, of which 2619 was concentrate and 50,915 ore. Of concentrate the Standard

MAP SHOWING MINING DISTRICTS OF NORTHERN ONTARIO

mine, Silverton, has contributed 1167 tons. The leading shipper has been the Sullivan mine, Kimberly, which shipped 19,709 tons of zinc ore and 834 tons of lead ore. During the latter part of February the Republic, of Slocan City, joined the list of shippers with a contribution of 19 tons.

SHEEP CREEK.—Two mine officials, Harold Lakes, superintendent for the Nugget Mines, Ltd., and E. V. Buckley, manager for the Queen Mining Co., had an unpleasant experience late in February. They were suspended for five hours in buckets on the aerial tramway of the Nugget mine while a severe snowstorm raged about them.

Normally the trip takes twenty minutes, but on the unlucky journey in question there were two forced stops, the last being for four hours over a 200-ft. canyon, where rescue by ropes was out of the question.

SAXON.—Recent development on the Noble Five mine, owned by James Dunsmuir and situated at Cody, has opened, on two or three levels, a 4-ft. shoot of ore whose existence was not suspected previously. The Noble Five has been subjected to deep development with good results. From the operating tunnel a vertical raise ascends, and from stations on this raise cross-cuts are run to the vein on various levels. Ultimately the workings of the Noble Five and those of the Reeo, higher up, also owned by Mr. Dunsmuir, will be continuous. Extensive diamond-drill work has been done and it is figured that there is ten years stoppage for the concentrator now being built. The fine-grinding floor of this plant will be equipped with Hardinge and Rogers mills. A battery of six Wilfley tables will be placed on the floor above, with two tables on the top floor. Rolls, jigs, classifiers, and flotation will be used. From its first crushing the ore, after being elevated to the bins, will be fed into the rolls, and then will pass to three sets of screens, from which the over-size will go to the jigs, an intermediate product to the upper tables, and the under-size to the lower tables. The tailing will be re-ground in the ball-mill, whose product will go to the classifier. There will be flotation equipment consisting of roughers and cleaners, the froth going to the lower tables for further separation. Lack of cars and other transportation delays has held back construction, but it is said that most of the machinery is in place and that the mill should be ready for its trial run early in the spring. The property is equipped with a 675-cu. ft. Rand compressor.

ONTARIO

KERR LAKE REPORT.—GOWGANDA NOTES.

CORALT.—During February the Kerr Lake mine produced approximately 100,000 oz. of silver, of an estimated value of \$150,000. Costs averaged a little under 50c. per ounce, and net profits for the month amounted to over \$100,000. The Associated Gold Mines of Western Australia, operators of the Keeley mine in South Lorrain, have bought 20 stamps now in the mill recently purchased by the Coniagas from the Trethewey. This equipment, together with a carload of cement for constructing a foundation for the proposed new mill together with other necessary building material, is to be transported at once to the property, and it is hoped to commence production by late summer.

The McKinley-Daragh will pay its regular dividend of 3% on April 1. Current net earnings are stated to exceed dividend requirements. The present surplus approximates \$500,000. Total disbursements by this company to date amount to 259% or \$5,751,163. The referendum taken by the various branches of the Union of Mine, Mill and Smelter Workers in Northern Ontario, for the purpose of deciding whether or not, in breaking away from the International it would be best to join the

'One Big Union', or organize a district union, resulted in a large majority in favor of joining the One Big Union. The vote is representative of the membership of the Union, but the latter comprises not more than 10% of the workers in the mines.

Harry Mills, Ontario Minister of Mines, makes the statement that in appointing a mining inspector to fill the vacancy on the staff of mining inspectors caused by the death last fall of A. H. Brown, he will select a returned soldier, keeping in mind the necessary qualifications. The Coniagas company is negotiating for the purchase of the Gamble-Thompson mining claims in the Gowganda district. The deal at present includes only an option to purchase. The Silver Ballion Mining Co. with property at Leroy Lake has purchased a \$30,000 mining plant formerly used on a mining property in Nova Scotia. The equipment is now in course of transportation to the property.

PORCUTINE.—The annual report of the Hollinger Consolidated for 1919 shows that year to have been the best in the history of the company. The recovery of gold was \$6,722,266, and other sources of income brought the total receipts up to \$7,063,099. Working expenses amounted to \$3,222,617, and net profits after deducting taxes, depreciation, and donations, were \$2,321,290. Of this, \$1,722,000 was paid in dividends and \$599,290 added to the surplus. The wages bill amounted to \$1,701,104. The number of tons of ore milled was 711,882, of the average value of \$9.75 per ton. The value of the ore-reserves was estimated at \$39,928,430, as compared with \$41,080,005 in 1918. The report makes public the news that the company has entered the oil-field by the purchase of the Herrington property of 3760 acres in Dickinson and Morris counties, Kansas, for \$115,195, the price including the sinking of a well by the vendors costing about \$35,000.

GOWGANDA.—The Trethewey will shortly make a second shipment of ore taken from the vein on the 108-ft. level, where the high-grade vein is widening and increasing in silver content. The Silverado, which is now employing 35 men, is obtaining satisfactory results and will shortly begin work on the Silverado Extension adjoining. Development will shortly be begun on the Bonsall claims, ore from which is now being sampled to determine the point where work will be started. The Kilpatrick Silver Mines, Ltd., has taken over the Kilpatrick claims next to the Miller Lake-O'Brien and begun operations. It will sink to the geologic horizon on which the Miller Lake-O'Brien has obtained rich ore.

SKENAD TOWNSHIP.—A good deal of interest is being taken in this area, adjoining the Boston Creek district, and many new companies are entering the field. The matter of transportation, however, presents a difficult problem. There is much activity in taking in supplies and machinery over the winter roads before the break up renders them impassable.

BOSTON CREEK.—The Miller Independence has completed its main shaft to the 500-ft. level and let a contract for cross-cutting to the main orebody. At the Peerless, formerly the Mondeau, a rich vein 5 ft. wide has dipped into the shaft below the 100-ft. level.

ALASKA

Hyder.—The fourth shipment of ore from the Premier mine, Salmon River district, has been made to the Tacoma smelter. The shipment amounts to 300 tons and the ore is reported to assay about \$275 per ton. Development is proceeding on the Big Missouri.— The tunnel on the Bush mine is reported to be in high-grade ore. The same is true of the Forty Nine. A cross-cut tunnel is being driven on the Unicorn. Up the Bear river the crew at work on the Lakeview mine is in ore.— The Indian Mines, Ltd., plans to resume development on its four claims situated on the west side of Cascade creek, opposite the Bush property. Development consists of three open-cuts on the outcrop and two tunnels. The open-cuts expose a well defined vein, which can be followed on the surface for about 2000 ft. The vein is quartz and appears to follow a wide dioritic dike which intrudes the greenstone schists. The minerals found include galena, sphalerite, and pyrite.— With the report that the old Portland Canal Tunnel Co. may be revived, interest is being manifested in properties of Glacier creek back of Stewart, B. C. The tunnel was an ambitious scheme started in 1912 to run 2000 ft. to tap at depth all orebodies of Glacier creek. An early opening of the Salmon River district is expected, the weather having been mild and much of the snow having already disappeared.

Juneau.—The Alaska Gold Mines Co. reports an operating deficit of \$277,481 for last year and, with its miscellaneous income deducted, a total deficit of \$275,128. This company's 1918 deficit was \$110,290.

A total of 738 ft. of development work was done in the company's property in the last quarter of 1919, consisting of the driving of man-way raises and bull-dozing drifts in connection with the opening up of new stopes. The mill was operated on a three-shift basis during the quarter. A daily average of 7528 tons was milled—the highest rate reached for any quarter since the mill has been in operation. The company's generating stations operated satisfactorily throughout the quarter and developed sufficient power for the operation of its mine, railroad, and mill, and an excess which was sold to other industries in the district. The labor situation improved somewhat during the quarter.

The town of Hope, situated on the Kenai peninsula, has been the scene of a silver-gold discovery that promises to develop considerable importance. The vein is said to be 6 ft. thick, the ore assaying \$77 per ton. A 3-in. stringer, it is said, assayed \$360 per ton.

ARIZONA

Jerome.—The main top orebody of the Jerome Verde Copper Co. has been cut on the 950-ft. level and the quality of the ore is said to be as good as that mined from above the 900-ft. level.

It is reported that the Bagdad Copper Co.'s mine in the Eureka district is being reopened. Twenty men are employed. A new road is being built and new machinery has been brought in.

Miami.—It is announced that the holdings of the Warrior Copper Co., which lie adjacent to the Inspiration Copper Co.'s property, have been sold to the Inspiration for approximately \$500,000. The Warrior Copper Co. was organized

several years ago and capitalized at \$1,600,000. Since organization it has produced intermittently.

CALIFORNIA

Allegany.—The El Dorado Co. has placed a 10-stamp mill in commission on ore from the dump. Development of ground below the old levels is proceeding under the management of T. J. Flynn. The property is controlled by Nevada capitalists.

Brandy City.—The Brandy City Mines Co. has completed a new tunnel to carry the sluicing flume into which gravel will be hydraulicked from the banks. The monitors are hampered by water shortage and are unable to operate at full capacity. Late storms have somewhat improved conditions.

Lincoln.—Thirty sets of lessees are active in this district and shipping ore is exposed at several points. The Robert Maris lease on the Wilkinson has exposed a 10-in. shoot, sampling \$200 per ton. The shaft is down 50 ft. and a drift from this point is following a seam of rich ore. Silver predominates.

Masonic.—A. G. Cook and associates have purchased the Pittsburg-Liberty group for the reputed price of \$32,500. The first payment, 25% of the purchase price, has been made and the balance will be met in \$10,000 installments. Plans are being made for the comprehensive exploration of promising ground. The property was a good producer several years ago.

COLORADO

Mayday.—Avery & Brandiger, lessees on the Idaho, are shipping ore said to be worth \$6000 per ton. The ore is the La Plata sandstone and contains free gold and sylvanite.

IDAHO

Coeur d'Alene.—Recent development work at the Giant Ledge property on Granite creek, four miles east of Murray, has opened up an excellent vein, according to L. W. Jackson, consulting engineer. Development plans involving an outlay of \$100,000 have been made.—T. B. Cosgrove, manager and foreman of the West Hunter company, who is driving the West Hunter cross-cut through the American Commander ground, says that there is now eight inches of high-grade galena in the face of the cross-cut.—The Silverado mining property, which is developed with thousands of feet of underground work, has been leased to four Wallace men—William Fahle, Knute Rosedale, Oscar Johnson, and Emil Peterson. The property is near Osborne, and the lease includes a 50-ton concentrator built four years ago and said to be in good condition.

Galena ore in a body 8 to 10 in. wide has been found at a depth of about 1000 ft. in the property of the American Commander Mining Co., according to J. L. Martin. The vein has been penetrated for 8 ft. without reaching the wall.

MISSOURI

Joplin.—The Jupiter Zinc Co. is making satisfactory progress with its mine south-west of Galena, near Wyandotte station on the Southwest Missouri railroad, and a good body of zinc and lead ore is being worked at a depth of 80 ft. The shaft will be sunk deeper, as the field-shaft shows a big

orebody at 108 ft. It is said the field-shaft shows a 60-ft. face of ore, with a width of 40 ft. There is a mill of 125 tons capacity at the new shaft. A sludge department is being added to the mill.

The Oronogo Mutual mine, which recently resumed operations after a shut-down while improvements were being made, will begin sinking another shaft to supply ore to work the plant for a greater production. The company built additional tramways during the shut-down, connecting the mill and mine at a distant part of the lease.

MONTANA

Butte.—The Anaconda Copper Mining Co. is now reported to be actively engaged in spending \$1,500,000 in a systematic effort to eliminate mine hazards in all its properties. As a part of the plan, 11 new positions have been created. The new officials will be known as safety and ventilation engineers and will devote their entire time to training men to avoid accidents and in studying means to improve underground conditions. Many of the mines are now equipped with canvas air-pipes, which, it is said, make the mines cooler in some cases than they were ten years ago, despite increased depth.

NEVADA

Ely.—The Consolidated Copper Mines Co. is making a drastic cut in its forces. The present payroll is about 250 men, which, it is understood, will be reduced to about 90. The pumps will be kept working and enough men retained to keep the mine in shape. No explanation for this step has been offered by officials.

WASHINGTON

Spokane.—C. A. Coffin, who purchased from Walter Donner the lease on the Coyote galena property, north-east of Colville, last fall, has financed a syndicate that will commence operations when the snow is gone. The only necessary preparation for shipping is the building of a wagon-road one mile long. The mineralized zone is said to be 500 ft. wide and ore can be immediately mined with a steam-shovel. Two assays showed: 122 oz. silver and $4\frac{1}{2}\%$ lead, and 423.44 oz. silver and 26.31% lead. There is about \$100,000 worth of ore now ready to ship.

The Silver Mountain Mining Co., operating on the old Daisy mine, five miles east of Daisy, is having machinery hauled to the property for a 50-ton concentrator. Several good veins have been uncovered recently in the Daisy mine and the property is now looking well. About 25 years ago considerable ore was shipped. Philo Seely is in charge.

MEXICO

The Mexican plants of the American Smelting & Refining Co. have increased operations to about 90% capacity and barring unforeseen disturbances will this year, for the first time in five years, contribute net earnings to the company's treasury.

Pachuca.—Hugh Rose, consulting engineer to the Santa Gertrudis company, reports that by the latter part of this year the El Bordo group, comprising the El Bordo, Malinche, and El Cristo mines, should be producing at the rate of 40,000 tons of ore per month, and recommends that the Santa Gertrudis milling capacity should be increased to provide for the treatment of 60,000 tons per month to include 20,000 tons per month from the Santa Gertrudis mine. The reduced production from the Santa Gertrudis itself will have the effect of prolonging its life. The directors have approved and authorized this increase in the milling plant, and its construction at an estimated expense of \$300,000 will be commenced at once.

It has just been reported that 136 miners have not been accounted for in the El Dorado mine where fire broke out recently; 204 of the 340 men working in the shaft where the flames are raging have been accounted for.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Albert Burch has gone to Wallace, Idaho.

Arthur W. Jenks is in New York for a few weeks.

C. M. Weld has returned to New York from Brazil.

Ralph Arnold has returned from Washington to Los Angeles.

F. R. Weeks is examining mining properties in Utah and Montana.

O. C. Ralston passed through San Francisco on his way from Niagara Falls to Seattle.

K. S. Twitchell, recently at Nicosia, on the island of Cyprus, is now living at Los Angeles.

Joel A. Battle, recently with the U. S. Bureau of Mines at Washington, is now at La Paz, Bolivia.

W. E. Mitchell has been appointed general mine superintendent of the La Blanca at Pachuca, Mexico.

A. H. Fay has resigned from the U. S. Bureau of Mines to engage in consulting work as engineer of oilfields.

G. S. McKay has accepted a position with the Mina San Juan y Anexas, at Cusihiuirachi, Chihuahua, Mexico.

L. C. Trent is at the U. S. Bureau of Standards, at Washington, where he is conducting some important experimental work.

N. C. Sheridan, of Wallace, Idaho, has been appointed manager for the Snake & Opportunity Mines Co., at Hillsboro, New Mexico.

Jerome A. Hilbert has been appointed superintendent of the Blue Ledge mine of the Mexican Smelting & Refining Co., at Copper, California.

G. A. Denny has been appointed consulting engineer for the Transvaal & Rhodesian Estates, Ltd., Finsbury Pavement House, London, E. C.

H. Lipson Hancock, general manager for the Wallaroo & Moonta Mining & Smelting Co., in South Australia, sailed for Sydney on the 'Sonoma'.

R. W. Prouty, formerly with the Phelps Dodge Corporation at Morenci, has accepted a position with the Old Dominion Co., at Globe, Arizona.

Algernon Del Mar has gone to Sinaloa, Mexico, to undertake metallurgical work for the Metatas Mining Co. He expects to be away three months.

Walter B. Robinson, recently of Portland, Oregon, is now employed as engineer by the Mexican Smelting & Refining Co., at Blue Ledge mines, Copper, California.

Ralph Kerns has severed his connection with the Inspiration Consolidated Copper Co., and has accepted a position in the engineering department of the Phelps Dodge Corporation, at Douglas, Arizona.

James Heggie has severed his connection with the Consolidated Kansas City Smelting & Refining Co., of El Paso, Texas, and is now associated with the United Verde Extension Mining Co., at Verde, Arizona.

Obituary

Andrew Muir, one of the pioneer engineers of California, died, at the age of 82, at St. Paul, Minnesota. He was born in Ontario, Canada, and spent his early manhood in South America. He built the Bozeman and Muir tunnels on the Northern Pacific railroad in Montana and helped to build the old Santa Cruz narrow-gauge line in California. In 1872 he was in charge of the Alps mine at Pioche, Nevada.

THE METAL MARKET

METAL PRICES

San Francisco, March 10

Aluminum dust, cents per pound	45
Antimony, cents per pound	11.00
Copper, electrolytic, cents per pound	18.75
Lead, pig, cents per pound	9.50-10.50
Platinum, pure, per ounce	\$145
Platinum, 10% iridium, per ounce	\$105
Quicksilver, per flask of 75 lb.	\$85
Spelter, cents per pound	10.25
Zinc dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

March 15.—Copper is quiet and easy. Lead is very strong. Zinc is dull and erratic.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 899 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.63 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

Edward N. Hurley, former chairman of the Shipping Board, discussing the new chartering agreement by which the Government cargo ships are to be operated says: "Our merchant fleet must not become concentrated in the hands of a few large steamship companies. If that should happen, these companies would soon find themselves facing difficulties similar to those that confront the Shipping Board with the only advantages favoring them, somewhat more flexible administration of affairs due to private ownership. These companies would have to establish agencies abroad, and develop large, complicated, but efficient operating organizations at home. This is something that cannot be done quickly even by a private company. Therefore they should be distributed among as many small companies as possible."

"At present close to 300 American steamship companies are organized, many of them operating American ships successfully in overseas trade. By September when the building program has been completed the Shipping Board fleet will consist of approximately 1000 steel ships of 11,000,000 tons. If these companies can be induced to buy an average of six ships each, we shall have our government cargo fleet almost composed of small companies will operate the ships with that close, energetic, resourceful, individual, clipper-day application so necessary for success, yet without notable increase in present operating organization. For they would continue to use brokers abroad until the more successful had earned money with which to get together fleets large enough to justify establishment of agencies of their own in foreign ports."

"Our merchant marine can succeed little better government-owned and privately operated than government-owned and government-operated. Passing of title must therefore be expedited as much as possible. Bankers and the investing public must help. Money immediately required will not be relatively large, and future payments will be mainly from earnings. For instance, if the world price on oil-fired cargo tonnage be today \$165 a ton, and if 10,000,000 tons of the shipping tonnage be on a 20% first-payment basis, and the rest in ten years, only \$30,000,000 will be required. Even this \$30,000,000 does not have to be raised all at one time as it will take two years to dispose of this tonnage. Surely our finances are such that this sum can be taken out of the regular channels of trade without undue disturbance."

"Bankers and shrewd judges of investment possibilities will help as soon as they realize our merchant marine can succeed despite foreign competition to hasten education of investors in shipping matters, as well as to gain credit road to result from this committee. Our reform merchant marine will succeed in face of competition from abroad, partly because ocean freight rates and shipbuilding costs will remain high for five years, but mainly because of our merchant fleet's advantage in oil-firing. Confidence will undoubtedly come down greatly during the next few years. This, however, will be because of increased production of life essentials as a result of water spending of money and less waste of effort upon luxuries non-essentials, rather than because of the general decline in commodity and other values."

Foreign quotations on March 16 are as follows:

Sterling, dollars:	Cable	3.72
	Demand	3.70 1/2
France, cents:	Cable	7.52
	Demand	7.50
Live, cents:	Demand	5.61
Marks, cents:		1.33

Eastern Metal Market

New York, March 10.

All the markets are dull and weak except lead and antimony and values have declined.

Copper is again lower and demand is almost negligible.

Tin values are following the highly erratic London market where speculation is rife. Buying here is confined to dealers and is small.

Lead is very strong and prices are higher. Supply is still inadequate.

Prices for zinc have again receded and buying has been light. The London market is a factor in this.

Antimony is strong and higher.

IRON AND STEEL

With production at the highest rate in more than a year and the prospect of further increase as spring comes on, the steel trade expects gradually to work out of the serious hamperings of recent weeks, says 'The Iron Age'. There has been no rush thus far on the part of the railroads to buy equipment, and the week has rather added to the evidence that the strained conditions in the industry are yielding.

A development of interest in the wire trade is the taking of orders by a large producer with the stipulation that the price will be that prevailing at the time of delivery, indicating the abandonment of the low prices of March 21 on wire products. Automobile manufacturers have cared little what they have paid for early delivery steel, as high as \$90 being reported for sheet-bars which in turn they have had rolled into sheets for car-bodies. At the same time a sale of sheet-bars is reported in the Chicago district at \$70.

Further signs appear of the reaching of the peak in pig-iron prices. An effort to advance foundry iron in eastern Pennsylvania to \$45 did not succeed and foundry iron is still available at \$40. Birmingham. There is much more inquiry for pig-iron for export, owing to the fact that it can be shipped to England for ballast with cotton at considerably less than recent freight rates and there is a chance of a fair movement if the exchange situation improves.

Exports of iron and steel in January were heavier than in December—369,000 tons against 254,000 tons. A considerable part of the movement, however, was to Japan and other countries not affected by adverse exchange conditions.

COPPER

There is almost no demand and values have further declined. Electrolytic copper for early delivery and up to June is quoted at 18.37½ to 18.50c., New York, the latter being the quotation of leading producers. That this could be shaded on desirable business is evidenced by the fact that on 500 tons for export yesterday 18.50c., New York, was quoted; export orders generally command a slight premium over domestic. Lake copper is quoted at around 18.50 to 18.75c., New York, depending on the delivery and the quantity as well as on the seller. While the market is at present weak and inactive, a better demand is confidently expected in the near future.

TIN

The highly speculative London market continues to be the predominant influence here. The feature this week has been the decided fall, almost collapse, of values there. Yesterday spot Straits declined \$14 per ton from the day before and was quoted at \$772 per ton, which contrasts with \$411 a week ago and with \$418 about two weeks ago. This movement has been up and down within these limits. Quotations for spot Straits in New York have followed these chances. The result has been that importers and dealers can do no reliable calculating and hence very little business for any position. The business that has been transacted has been between dealers with consumers doing little and apparently

not at all anxious. This would indicate that they are well supplied. On Thursday last week about 300 to 400 tons of futures was sold at around 63 to 63.25c., with the spot market dull at 62c., New York. Today spot Straits is quoted at 60.25c., New York, with futures at about 62c. The slump on the British market is based probably on the labor situation in the British steel market which is affecting the tin-plate output. Arrivals thus far this month have been 500 tons, with 5465 tons reported afloat.

LEAD

Conditions in this market are unchanged; if anything the market is stronger. Late last Friday the American Smelting & Refining Co. advanced its price another ¼c. to 9.25c., New York, or 9c., St. Louis, but the outside market was already higher. Today independent sellers and producers are asking 9.50c., New York, and 9.15c., St. Louis, as a minimum for spot and early delivery. The metal is very scarce especially for spot. What is regarded by some as a good sign is the fact that consumers are not anxious to buy futures and one large interest is of the opinion that lead will probably not go any higher but if it does the advance will be small and temporary. A short supply with good consumption is a brief description of this very strong market.

ZINC

Values have again receded in the past week and demand has been and is very light, whether for domestic or foreign consumption. This market has followed the fluctuations of the London market where quotations have for the most part steadily declined and have been also speculative. Due to advances from the other side on Monday a selling wave appeared and values fell to 8.37½c., St. Louis, but yesterday the market was firmer there and as a result prime Western here for early delivery up to July and in some cases into the third quarter was quoted at 8.50 to 8.62½c., St. Louis, or 8.55 to 8.97½c., New York. What business is being done is largely by speculators or dealers.

ANTIMONY

The market is stronger with wholesale lots for early delivery quoted at 12c., New York, duty paid.

ORES

Tungsten: The market is very quiet with some business done in low-grade ores at \$6 to \$6.50 per unit in regular concentrates. Other grades range up to \$15 per unit. There is no news as to the tariff question. One dealer predicts confidently that no duty can possibly pass the Senate.

Ferro-tungsten is quoted at \$0 to 90c. per lb. of contained tungsten.

Molybdenum: Quotations are nominal in a quiet market at 75 to 80c. per lb. of MoS₂ in regular concentrates.

Manganese Ore: A large quantity of foreign ore has been sold recently for early and extended delivery but details are withheld. There are possibilities that more may be sold. The last quotation was 80c. per unit, seaboard, but this could be shaded on a desirable order. Imports in January are 21,463 gross tons against 47,504 tons in January 1919. The total for the seven months ended January 31, 1920, was 128,822 tons against 293,971 tons for the same seven months a year ago.

Manganese-Iron Alloys: Demand for ferro-manganese is quiet and values are firm. Domestic producers are quoting \$175, delivered, for third quarter and \$160 for last half. Very little spot alloy is available. For such as has been sold and is still obtainable \$200 is asked and obtained. Some British alloy for shipment in the last half is held at \$165, seaboard. About 21,000 tons of spiegeleisen is under negotiation for export. Domestic demand is light at \$57 to \$60, furnace.

Book Reviews

The ABC of Iron and Steel. Edited by A. O. Backert. Third edition. Pp. 363, ill., index. The Penton Publishing Co., Cleveland, Ohio. For sale by 'Mining and Scientific Press'. Price, \$5.

This is the best single book that we have seen covering the general features of the iron and steel industry. The principal part comprises 23 chapters, each discussing some particular branch or aspect of the industry and each written by an expert in that particular line. Thus the mining and transportation of iron ore, the manufacture of coke, and the manufacture of iron, steel, and the principal steel products, together with the processes used are all discussed in order. The text is accompanied by many illustrations, both photographs and diagrams. Appendices contain statistics of the industry and a directory of iron and steel works in the United States and Canada, arranged both alphabetically and according to products. The principal changes made in the third edition as compared with the second, include bringing these appendices up to date, the insertion of an entirely new chapter on malleable castings, and a great deal of new matter on the treatment of the rolling-mill industry. While the various chapters are so complete as to contain much new information for the expert, they are so clearly written as to form fascinating reading for the layman.

Complete Practical Machinist. By Joshua Rose. Twentieth edition. Pp. 536, ill., index. Henry Carey Baird & Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

It is 26 years since the first edition of this useful book appeared. The work has been considerably revised and enlarged for the new edition, and while the earlier editions were devoted almost entirely to the cutting-tools themselves, the present volume also discusses at considerable length the machine-tools in which the cutting-tools are used. The book is written for the practical machinist without technical education, but many technically trained engineers could also find it useful. The chapter-headings are as follows: Cutting Tools for Lathes and Planers; Cutting Speed and Feed; Boring Tools for Lathe Work; Screw-Cutting Tools; Lathe-Dogs; Turning Eccentrics; Hand-Turning; Drilling With the Lathe; Boring-Bars; Slotting-Tools; Twist-Drills; Tool-Steel; Taps and Dies; Vise-Work; Fitting Connecting-Rods; Milling-Machines; Tool Grinding; Marking Out Work; Machine-Tools; Precision-Lathe Attachments; Gear-Shapers; and Miscellaneous Attachments. There are also three short chapters at the end of the volume on calculation of the speed of wheels, etc., on setting slide-valves; and on repairing pumps. We are inclined to believe, if the book were entirely re-written, that more space would be devoted to such subjects as high-speed steel, grinding-machinery, and other relatively new developments in the industry. However, although perhaps not very well balanced, the book is a useful one.

Outlines of the Geology of Brazil to Accompany the Geologic Map of Brazil. By John Casper Branner. Bulletin Geological Society of America, Vol. 30, No. 2, June 1919. 149 pp. with geologic map and illustrations. This bulletin can be obtained from the Geological Society of America, 77th St. and Central Park, West, New York. Every geologist or mining engineer desiring to inform himself on the geology of Brazil should secure a copy of Prof. Branner's compendium. While, of necessity, this bulletin does not contain all known information as to the geology and mineral resources of the republic, yet it does contain the key to all

such information, as well as representing graphically, so far as the scale of the map permits, all that is known of the geological formation.

Probably no one is better posted than Prof. Branner on this subject, as he has been accumulating data since his first visit to Brazil in 1911, and has spent many years in geological research in that region. Moreover Prof. Branner is a Portuguese scholar, a very important matter, since that is the language of the country and much that has been written concerning it is in that tongue only. He is also the author of 'Geologia Elemental', a text book in Portuguese written for the schools of Brazil.

The geology is treated under four main heads: (1) Stratigraphic geology, describing the various formations from the Archean to the Tertiary, (2) General and economic geology by States, (3) Metallic minerals, and (4) Non-metallic minerals.

Under stratigraphic geology the following great divisions of geologic time are recognized:

A. Archean. The rocks of this era consist of granite, gneiss, quartzite, marble, and crystalline schist. These cover a large area in eastern Brazil and the larger part of the country north of the Amazon, and are likewise exposed in some portions of western Brazil. It would indeed seem likely from an inspection of the map that the Archean or Brazilian complex forms the basement formation of the entire region and that it exists at not a great distance from the surface even where covered by later formations. In the Archean are found gold, copper, platinum, tungsten mica, graphite, potash minerals, precious stones, and excellent building-stones. Since the Archean is so wide-spread in Brazil, it would appear reasonable to conclude that many deposits of the above-mentioned economic minerals await future discovery; but considering the depth of surficial decomposition products, the large areas of virgin forests and the lack of means of communication, such discoveries will probably be spread over a long period of time.

B. Early Paleozoic. This group of rocks cannot be clearly defined for lack of stratigraphic data. No fossils have been found in any of them, but for purposes of discussion, the author places the top of the Archean at the base of the quartzite called itacolumite in Minas Geraes. The rocks vary from soft clay-slates to the hardest of quartzites. Economically the Early Paleozoic contains most of the profitable gold-lode mines and it is the indirect source of the gold found in the old placers. This series likewise contains the great iron (Itabirite) and manganese deposits, recently investigated by Harder and others. Some investigators also consider this series as the original source of the diamonds and other precious stones. Without going into details, it is evident that the Early Paleozoic of Brazil is of the greatest economic importance and of the highest scientific interest.

C. Silurian. The oldest known fossils, found in Brazil in the States of Amazonas and Pará, are Silurian. The rocks are marine sediments, mostly thin-bedded sandstones.

D. Devonian. In the Amazon region the Devonian rocks are white and yellowish sandstones and black and reddish shales; in Paraná and southern São Paulo, conglomerates, sandstones, and shales; and in Bahia, the Caboclo shales of Branner are supposed to be Devonian. Economically the conglomerates of Paraná are supposed to be the source of the diamonds of that State. In Bahia the Caboclo shales are available for the manufacture of portland cement.

E. Carboniferous. All the Carboniferous rocks of Brazil belong to the Upper Carboniferous. In the Amazon region the Carboniferous rocks are shales, sandstones, and limestones, the last containing marine shells. No coal-bearing beds have been found in them. The Bahia beds are pinkish quartzites, sandstones, and conglomerates from which carbonades and diamonds are derived, and it is considered likely that these beds are simply the northern extension of

the diamond-bearing beds of Minas Geraes, although in neither state is the Carboniferous age of the diamond-bearing series as yet certainly determined.

F. Permian. The Permian rocks comprise nearly all kinds of sediments and are remarkable in containing, in the Lower Permian, beds of glacial origin. Permian rocks cover a wide area, extending from Maranhão south to Minas Geraes and continuing south in a narrower area. Economically the Permian contains coal beds in Paraná, Santa Catharina, and Rio Grande do Sul; and here too belong the Iraty bituminous shales of the southern states. The limestones are wide-spread and are likely to be of national importance in the manufacture of cement. It seems quite possible that some of the important occurrences of diamonds in Brazil are in glacial beds at the base of the Permian.

G. Triassic. The Triassic rocks are soft reddish sandstones, usually horizontal, but more or less faulted and intruded by sheets and dikes of diabase. They cover large areas in Maranhão and in central, western, and southern Brazil.

H. Cretaceous. The Cretaceous formations cover large areas. Economically the abundant limestones are available both for building-stone and portland cement.

I. Tertiary. The Tertiary beds comprise both marine sediments, brackish-water and fresh-water deposits. Economically the coastal belt of Tertiary sediments from Bahia northward are likely to be valuable for underground water. At several places in the States of Bahia and Alagoas, the Tertiary beds include lignites and bituminous shales, and this is likewise the case with the lake deposits of Minas Geraes and São Paulo. These shales were formerly used at Taubaté for the manufacture of gas. Clays for the manufacture of bricks, tiles, sewer-pipes, and common pottery are abundant.

General and Economic Geology by States. Under this head are given many details of the geology as well as bibliographies relating to each State, these descriptions comprising the larger part of the bulletin.

Metallic Minerals. Under this head the following are briefly referred to: iron, gold, silver, copper, zinc, lead, tin, manganese, nickel, chromium, platinum, palladium, aluminum, tungsten, mercury, and molybdenum. Of these iron, gold, and manganese only are known in commercial quantity.

Non-metallic Minerals. Under this head coal, lignite, and peat, petroleum and oil-shale, asphalt, building-stone, marble, limestone, gypsum, anhydrite, kaolin, clay and fullers earth, glass sands, asbestos, talc, mica, salt, nitre, graphite, bauxite, monazite, zirconia, phosphates, diamonds, and other precious stones and carbonades are mentioned. Of these only the following are as yet known to be in commercial quantity: Coal, lignite, and peat, oil shale, granite, building-stones, marble, limestone, gypsum, potters clay, glass sand, talc, salt, nitre in caves, bauxite, monazite, zirconia, phosphate, diamonds, and carbonados.

Under the head of mining laws it is stated that mineral deposits go with the soil, whether that is owned by the State or individuals.

H. W. Turner.

The publication of a new and revised edition of the 'Prospector's Field Book and Guide' is announced. The book originally written by H. S. Osborn has been re-arranged and enlarged by M. W. von Bernewitz, formerly assistant editor of the 'Mining and Scientific Press', and will appear about March 20. Those familiar with the former work, and acquainted with the reputation of Mr. von Bernewitz will be glad to learn of this revision. A substantial flexible binding will add to the utility of the book. Henry Carey Baird & Co. are the publishers and the price is \$3. A copy can be had from the Book Department of the 'M. & S. P.'

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE LARGEST GYRATORY CRUSHER

The largest crusher in the world was built by the Traylor Engineering & Manufacturing Co. at its plant at Allentown, Pennsylvania. Some of the features are given here.

There was nothing startling in building this enormous machine, except the fact that it weighed more than 800,000 lb. and was completed in ninety working days, a feat in crusher-building made possible by the competent organization that H. L. Miller, general manager, has built up. He had kept in close touch with the modern trend of quarry-

crushers of even greater capacity than the present 'largest crusher in the world'.

The most essential part of any gyratory crusher is the eccentric, for here the power is applied that does the crushing, therefore the bearing pressures are very high. To overcome the high pressures in such crushers as the 60-in. and larger type, an eccentric of extra size is needed; one that has a positive means of lubrication, as well as greater proportional bearing area than other eccentrics. To keep the eccentric bearing pressure within safe limits, it required an eccentric over 8 ft. long and 45 in. diameter, having 9900 sq. in. of bearing surface for the 60-in. gyratory.

All 'Bulldog' eccentrics are fitted with a self-aligning journal bearing, which is loosely held to the shaft and around which the eccentric rotates.

This journal absolutely prevents any binding in the eccentric from any cause, thus greatly reducing the friction in the same. To efficiently lubricate the eccentric under all possible working conditions, a fully submerged pump of the gear type attached to and operated by the gyratory movement of the eccentric-journal bearing is used. This pump forces the lubricant up through the inner eccentric bearing to an oil channel at the top, thence it returns to the pump by way of the outer eccentric bearing; a portion being diverted to the main countershaft bearing and the cut-steel gears by means of which the eccentric is rotated.

As the gears run in a continual bath of oil, a quiet and easy-running machine is assured. The Hewes spider is used in all 'Bulldog' crushers to support the shaft at the top which carries the crushing-head. It is one of the features that made possible the 60-in. crusher.

The Hewes spider, like many other great inventions, is simplicity itself, for, unlike other gyratory crusher spiders, with their massive and useless spider ring, it consists only of an arched beam of box section, having the ends machined to a taper and a hub at the centre bored out to receive the all-steel shaft suspension. The tapered ends of the spider fit into pockets or recesses provided on either side of the top shell or section of the crusher, and when once they are drawn down into the pockets, metal to metal, by the extra large holding-bolts, the spider virtually becomes a part of the top shell.

Being of the low-arch type, it is possible to suspend the shaft at the point of no gyration, which is within the confines of the pockets, thus preventing any possible bending or twisting of the spider. This feature, combined with the great strength, light weight, and ease in handling, makes the Hewes spider one of the most notable improvements that has ever been brought out in gyratory crusher design.

The shaft, that all-important part of a gyratory, is shorter and 100% stronger in the 'Bulldogs' than in other makes of gyratory crushers. It is bend-proof in other words. Owing to its great strength a much higher proportion of the power used is consumed in actual rock-breaking than in other gyratory crushers, resulting in a greatly increased capacity with a smaller power consumption per ton of material crushed.

Traylor 60-in. Gyratory Crusher

operation, had seen the need for the 'largest crusher in the world' coming for some time, so when it arrived he was ready to take the order and guarantee a delivery that would have been impossible, except for his foresight in equipping the new shops with machine tools and cranes capable of handling the parts of a crusher even bigger than the 60-in. 'Bulldog' gyratory. The following figures give an idea of the size of the machine:

Part	Weight, tons
Shaft complete with crushing-head.....	65
Middle shell	51
Top shell	50
Bottom shell	48
Spider (Hewes type)	29
Eccentric with cut-steel main gear.....	12

There are features embodied in the design of the 'Bulldog' gyratory crusher that make it practicable to build

CONSTANT POTENTIAL CHARGING EQUIPMENT FOR AUTOMATIC CHARGING OF MINE-LOCOMOTIVES

For the automatic charging of mine-locomotives having Edison storage batteries the new C-II charging-panel shown in the accompanying illustration has been designed by the Cutler-Hammer Mfg. Co., of Milwaukee. It may be connected to a 250 to 275-volt direct-current circuit, since this is the service available at most mines. The equipment consists of a slate panel supported by a floor-type mounting-frame having the charging resistance self-contained. A

Mine-Loocomotive Charging-Panel

sheet-metal roof protects the charging resistance and the magnetic switches on the panel from mine drippings. The switch equipment on the front of the panel consists of a main-line knife-switch with renewable fuses, magnetic main-line contactor, voltage relay, and shunt trip-relay.

The main-line contactor, which connects and disconnects the battery from the line, is controlled through the voltage relay and the shunt trip-relay. The former prevents it from closing unless the line voltage is of sufficient value for charging, and causes it to open if the power fails or the line voltage drops below a predetermined value, thereby guarding against the batteries discharging back into the line. On restoration of the power after a power failure the main-line contactor automatically re-closes, and the charge is continued. The shunt trip-relay is connected to the ampere-hour meter on the locomotive and when the battery is fully charged the ampere-hour meter will energize the relay, which in turn causes the main-line contactor to open and disconnect the battery from the line. This relay also opens the contactor should the line voltage become too high. Thus the voltage and shunt trip-relays permit charging only when normal conditions prevail on the line; that is, the supply voltage must lie between the limits for which the two relays are set.

The Hauck Manufacturing Co., of Brooklyn, New York, has issued bulletin No. 119, which illustrates and describes in detail the many different types of oil burners manufactured by the firm. The book has numerous pictures showing the practical application of the Hauck burners to various types of furnaces.

COMMERCIAL PARAGRAPHS

H. A. Lynch, engineer for The Dorr Company, is on his way to South America, where he will visit Peru, Chile, and Bolivia. He can be reached care of the Hotel Londres, Antofagasta, Chile.

Bulletin No. 425 has just been issued by the Denver Fire Clay Co. It describes the company's entire line of muffle-type assay-furnaces, including those fired by oil, gas, gasoline, and coal or coke. It is an attractive and comprehensive publication.

R. S. Webber, who has been in the Michigan copper region the past three months for the Ingersoll-Rand Co., was promoted March 1 to take charge of the company's interests on the Gogebic Range, with headquarters at Ironwood, Michigan.

Booklet 121 has been prepared for the convenience of those who wish to see at a glance the styles and capacities of air-compressors built by the Sullivan Machinery Co. No attempt at description has been made; and the details shown in the tables are merely the principal dimensions and power requirements. A complete bulletin is issued, descriptive of each type, and any one, or all, will be sent the prospective purchaser upon request.

It is a known fact to many mining men that a considerable amount of lubricating material is wasted, particularly where common black oil is used for lubricating mine-car wheels. O. S. Newton, general superintendent of the Sunday Creek Coal Co., after investigating the apparent antagonism of mining men against high-grade semi-liquid lubricants, found that it is due largely to the lack of efficient methods of applying these lubricants. He therefore devised an oiling nozzle which renders it very easy to apply the lubricants to the car wheels. This device is of great simplicity and its use eliminated the waste material, no matter whether grease or oil is used. The Wolf Safety Lamp Co. has undertaken the manufacture of this device and will distribute it along with its line of mine lamps.

The following pointers on the use of wire rope appear in 'Leschen's Hercules', published by the A. Leschen & Sons Rope Co. A frequent cause of sudden wire-rope breakage is overstrain, and the best rope produced can as surely be overstrained as an inferior rope—not so easily or so soon—but it can be. There is a point of stretch in a rope called its elastic limit. Up to that point a rope will stretch and upon release from strain will so completely recover that no permanent set is appreciable. The handling of loads within the elastic limit of a rope may be repeated again and again, but should the strain be sufficient to stretch the rope beyond that limit even once, a part of the steel's vitality is gone and it becomes a set or a dead rope, and, even though sudden breakage may not immediately follow, early deterioration begins. The presence of brittle wires in a failing rope usually points to overstrain.

'Crucibles—Their Care and Use' is the title of Booklet No. 190-A, issued by the Joseph Dixon Crucible Co., who will be glad to supply a copy to those interested. Many refinery men do not fully appreciate the importance of keeping and handling their crucibles in a manner which will ensure the greatest number of heats with the least danger of accidents. The importance of the subject seems to be underestimated, and crucible users will find it to their advantage to give the matter more thought and attention, and instruct their furnace-men, melters, and others accordingly. As any defect in, or accident to, a crucible is an exceedingly annoying as well as an expensive matter, and as such occurrences are in most cases due to improper or careless methods in the annealing or handling of crucibles, the suggestions in this booklet should prove valuable, as they are the result of long experience and the best thought and knowledge on the subject.

T. A. RICKARD, . . . Editor

AN International Mining Convention will be held at Seattle on April 7 and the three following days. This convention is organized under the auspices of the Puget Sound section of the American Institute of Mining and Metallurgical Engineers and the Seattle Chamber of Commerce and Commercial Club.

ON another page we publish the second of a series of articles on the ore deposits of Mexico, by Mr. S. J. Lewis, a mining geologist thoroughly familiar with his subject. It will be noted that he illustrates his text with numerous drawings explaining the structural relations of the orebodies. These we believe will be appreciated by the men in charge of mines, in Mexico particularly but elsewhere also, because they give graphically the information most useful for aiding intelligent exploration.

WE are delighted to publish the brief, but deeply suggestive, article by Mr. Grant H. Smith on the beginnings of mining and of civilization. The fascination of a sketch such as this will send some of our readers to the nearest library, to plunge into the writings of Flinders Petrie, J. H. Breasted, and Gaston Maspero. In days like these when things are so much out of gear there is equanimity to be found in reading about men and mines in days so far detached from our existing turmoil. Someday somebody will be writing about our upsets of today as if they were mere thank-you-ma'ams on the road to progress.

IN our issue of December 13, 1919, we published the text of an address delivered by Mr. George L. Nye, as special counsel for the American Mining Congress, at the St. Louis convention of that Congress. In the course of Mr. Nye's arraignment of Minerals Separation, Ltd., he mentioned Kindersley and Pusch, and said they were understood at that time to have been agents of the German metal trust. Our attention has been drawn to the falsity of this reflection upon the loyalty of Sir Robert M. Kindersley and Mr. Emil Pusch. The former is a native-born Englishman and the latter, who is of Russian origin, has been a naturalized Englishman for many years. Both of them are, and have been for many years, members of the well-known firm of Lazard Brothers & Co. of London, Paris, and New York. Sir Robert is a governor of the Bank of England and the governor of the Hudson's Bay Co. During the War, he was the head administrator of the War Savings Bureau for all

England. Mr. Pusch was appointed a member of the British Mission to Russia and acted as such, and the loss of his two sons—officers in the British army—attests his devotion to the Allied cause. We regret the publication, even at second-hand, of any reflections upon their loyalty to their own country or to the Allied cause.

HORWOOD'S method of preferential flotation has been applied successfully to the lead-zinc ore of Broken Hill, in Australia. In this issue Mr. H. L. Hazen describes the results obtained in tests upon a copper-zinc ore in California, using a method that is a modification of the one devised by Mr. E. J. Horwood in 1912 and described by Mr. Allan D. Rain in our issue of October 7, 1916. Mr. Hazen recovered 37.6% of the copper as cement and 40.1% more copper in a product low in zinc. His zinc concentrate assayed 55.8% zinc and contained 54.6% of the zinc in the copper-zinc ore, not counting the further recoveries of copper and zinc concentrates to be made from the middling when returned for re-treatment in the flotation machine.

ACCORDING to the 'Neue Zürcher Zeitung', fine gold has been changing hands in Germany at the rate of 67,000 marks per kilogramme, as compared with a mint value of 1395 marks before the War. This measures the financial collapse of Germany. In the bazaar at Aden, gold sovereigns have sold for 37 shillings. At Rangoon, the customs authorities seized 2500 sovereigns and 3000 American \$20 gold pieces that were imported illegally on the steamship 'Hongmoh'. As regards the actual price of silver in London, Samuel Montagu & Co., to whom we owe the preceding data, state that it is probable that the extent of the premium on the currency pound is of more importance than the relation between the supply and demand for silver because the price of gold is an index of the American exchange, which establishes the par between the price of silver in New York and London.

INTELLIGENT mining under most circumstances requires systematic current sampling of working-places. There will be, of course, a varying degree of refinement, depending upon the width and extent of the orebodies and the character of the vein-matter and of the country-rock. Sometimes it is possible to distinguish definitely by appearance between material that should or should not be broken, or that should or should not be sent to the surface, even though breaking cannot be avoided.

More frequently assays are necessary. Even if it be not essential to maintain a fixed grade for shipment there is always a line somewhere beyond which 'rock' ceases to be 'ore', that is, too low-grade for profitable exploitation. Selective mining must be employed; and the guide for efficient selective mining is adequate sampling of doubtful blocks and prompt assay-returns. We have known instances where the stope-samples were considered of so little importance that they were set aside in the assay-office, so that when the results were finally reported nearly a week had elapsed after the samples were taken; in the meantime work underground had been suspended or inconvenienced; or perhaps the shift-boss had guessed at the grade and the material had either gone as waste into the filling or was already well on its way to the smelter. There must be dispatch from the time the sampling is done until the result is entered in the notebook of the man, directly in charge of the stope being worked. This is one of several excellent points in the scheme of sampling practised by the North Butte company, as described on another page by Mr. William Huff Wagner, who, prior to entering the service of the Government, was geologist and engineer to that company.

RETURN of enemy-alien property vested in the Public Custodian is raising interesting problems in South Africa, as in the United States. The Custodian of Enemy Property in South Africa and the Public Trustee of the United Kingdom together hold large blocks of various gold-mining shares, a small part of which has been sold, by arrangement with the Custodian, to 'friendly' shareholders. In most cases, however, no such transfer has been effected. The Johannesburg correspondent of the 'Financial Times' states that a pronounced weakness in the quotations for the two Modderfontein mines is due to the fact that "it is no longer possible to deal with the large enemy holdings of these two companies". The South African Custodian has shown an inclination to be lenient with the individual possessions of interned enemy subjects, because there was no seizure of Britishers' property by the authorities when it remained in the possession of the Transvaal and Free State during the time of the Boer war. The richer mines, however, were worked for the benefit of the South African Republic of Krüger and his friends. In any event, it is a fact that Section 7 of the Peace Proclamation provides for the return of the assets of German nationals resident or domiciled in the Union of South Africa at the outbreak of the War, on proof of residence and title, subject to the Custodian's fees. No less than 66,500 shares, or one-fifth the capital, of the New Modderfontein passed into the hands of the Custodian; and during the War the market-value of the stock rose from £12 to £35 per share. Obviously it was fortunate for the German holders that their stock was locked up for the five years during which most of them were likewise locked up in the internment camp at Maritzburg. They could not sell their shares while in duration and now they resume possession of their property at a trebled valuation, plus the dividends that have accumulated. A sliding-scale tax has been suggested on

this unearned increment, but only as an expression of goodnatured humor. The directors are being blamed by some people for not having made a deal for the purchase of the stock while it was in the Custodian's keeping. Now it is too late and there is a fear that the liberated Germans will proceed to take advantage of the high price, thereby spoiling the market. That is why the quotations are low. War hath its humor no less than peace.

A UNIQUE phase of the labor problem in South Africa is an unwritten law known as the 'color bar'. By its operation natives are excluded from the performance of 'skilled work' at the mines; and the tendency in recent years has been so to extend the definition of skilled work that there is no chance whatever for the native to improve his status or his pay, no matter how skilful or efficient he may become. This has come from humoring the less competent of the whites who have bluffed the operators by threats of a strike. It appears that many of the natives are far better qualified to do certain kinds of work than are the European bosses in whose charge they are, the effect being to decrease the attitude of respect for the white man on the part of the Kaffir, as he becomes conscious of his own superiority. The remedy, as pointed out by those who seem to understand the native best, is voluntarily to abolish the color bar in its entirety before the native himself forces its removal; this he can and will do as soon as he realizes his own economic strength. Those who favor this move argue that while the black man is exceedingly proficient at certain tasks, his capacity is limited and that he will never compete seriously with the white man in positions of larger responsibility. A few incompetents presumably would be supplanted; others would doubtless be stimulated by competition to greater exertion and greater efficiency to retain their places. This would be an obvious advantage all round. The native African, on the other hand, would have an opportunity to exercise his best ability with the knowledge that he would be advanced on a basis of proved merit. There are many angles to the native labor problem; yet it seems to us that the stand taken by the opponents of the color bar is sound; that the status of the native should be regulated by capability, rather than by an arbitrary and artificial standard, if it can be done without the risk of inciting the disturbance of peaceful relations between the black and white races—for upon that the stability of civilization in South Africa depends.

FALLACIES are hard to kill. We note that Mr. Herbert Guedalla, chairman of the National Mining Corporation, a highly influential financial combination in London, stated at the recent statutory meeting that the main object of his corporation is "to establish an industrial basis for mining, especially in the baser metals". That is well enough, although mining is an industry, despite anything Mr. Guedalla can do. What he meant probably was that he and his friends intend to subordinate the stock-exchange game to the production of the metals. So far, so good. Next he said: "We wish to eliminate as far as possible the element of speculation,

and for this purpose we propose not only to attend to the production of the mine, but to see that its products are marketed to the best advantage". This should not be a new departure, for it is the basic purpose of mining to produce mineral and sell it at a profit in the nearest market. Mr. Guedalla talks like an amateur. Again it may be presumed that he is hinting at abstention on his part and on the part of his associates from using the mine chiefly as an excuse for queer dealings on Throgmorton Avenue. That we readily believe, knowing the high character of the directorate; but no man by much thinking or by any number of resolutions on his part can eliminate speculation from a business so adventurous as mining. When it ceases to be speculative, it will die of inanition. Another remark of the chairman of the National Mining Corporation is worthy of note: "There may be lucky flukes in mining, but the main element of successful mining is the possession of ample capital for development and machinery". That is an exaggeration. The first thing in mining is to find ore and the second is to stay with it. No amount of capital can make a mine unless an orebody of adequate size is developed, and while to do that calls for the expenditure of labor and money, it is quite certain that the pre-requisite is the necessary raw material, that is, the large tonnage of ore upon which all subsequent operations are predicated. In short, mines are made by mining engineers, not by financiers.

The Greatest Gold Mine

Two years ago we reviewed the records and resources of the leading gold mines of the world and decided that the New Modderfontein, in the Witwatersrand district of South Africa, was the premier. According to statistics recently published, this property had 1860 acres, or 1265 claims, of which 270 have been exhausted; the ore-reserve is distributed over 281½ claims; the undeveloped area comprises 613 claims; 96 claims are recognized as unprofitable; and 4½ claims are allowed for dikes and faulted ground. During last year 29 claims were worked out. The yield of ore averaged 31,750 tons per claim. There remain 520 ore-bearing claims that are intact, and these should yield 14,750,000 tons, in addition to the 8,850,000 tons actually in reserve, that is, blocked out and sampled. The average gold content is 8.6 dwt. per ton. On the basis of an output of 100,000 tons per month, there is 7½ years supply assured and 12 years more probable. During the year ended June 30, 1919, the mills treated 920,500 tons, the average yield from which was 43s. 10d., as against a working cost of 20s. 2d. We would convert this British currency into dollars, if it were of any use, but the fluctuation in exchange renders it futile. A dollar is equal to about 5½ shillings at the present time. The working profit was £1,089,891 and the dividends £875,000, on a capital of £1,400,000. Direct taxation by the governments of South Africa and Great Britain absorbed £215,000. The premium of 17½ on gold up to the end of January yielded an additional profit of £121,000 for the current year; this sum ap-

parently will be more than doubled before the end of the fiscal year, on June 30. The chairman of the company, Sir Evelyn Wallers, stated that to yield a clear 7½ interest and provide instalments to reinstate capital, carrying interest at 5½, a dividend that continues for 20 years is worth almost exactly ten years purchase. Thus on the actual annual dividend of £3 per £1 share, the shares of the Modderfontein are worth £30, whereas they have been selling at £36. We may add the information that the New Modderfontein Gold Mining Company was organized in 1888 and started milling with 10 stamps in 1892. The present milling plant includes 236 stamps and 15 tube-mills, having a nominal capacity of 100,000 tons per month. The development and equipment of the mine involved an outlay of about £1,200,000. The ore, a gold-bearing basket, is 8 feet wide and dips flatly, so that the workings are only about 2000 feet deep. Dividends to date amount to £5,198,750. In the next 12 years the mine ought to yield at least twice as much more. Thus in a life of 40 years the mine ought to yield 75,000,000 dollars to its owners. Measured by its past performance and its assured prospects, it is, we believe, the greatest gold mine in the world today.

The Great Disillusion

In those days, which now seem so distant, before the Great War, some of us read Mr. Norman Angell's 'Great Illusion' and derived comfort from his insistence that warfare, even successful warfare, had become unprofitable because it was an economic impossibility for one nation to enrich itself by subjugating another, and that the wealth of the civilized world was founded upon credit and commercial contact to such a degree that the destruction of an enemy's credit and the breaking of economic contact with him would be almost as baleful to the victor as to the vanquished. Mr. Angell has not escaped ridicule, for the War seemed to knock his theory to pieces; yet today the plight of the world affords ample justification for much that he said. Our readers have read 'The Economic Consequences of the Peace' or they have read excerpts from it in the daily press. This book has had a profound influence upon the thought of the day, an influence, we think, in excess of its merit as a sustained argument. The author, Mr. J. M. Keynes, was official representative of the British Treasury at the Peace Conference and sat as a deputy on the Supreme Economic Council. He is a professional economist and had unusual opportunities to see the negotiations from the inside. When he saw they were going wrong, from his point of view, he resigned, and forthwith published a highly rhetorical attack upon the whole affair. The picture he gives us is of three men, Clemenceau, Lloyd George, and Wilson, of whom Clemenceau was the only one with a clear policy. That policy was to crush Germany so thoroughly that France would never again be in danger of invasion. The British premier is represented as having an eye on domestic politics and scheming for the purpose of strengthening his personal position at home, while President Wilson is described as a simple-

minded obstinate idealist who was more easily bamboozled than debamboozled. The Fourteen Points, accepted as the basis of the Armistice, constituted part of a solemn contract, which became "lost in the morass of Paris". The humane aspirations of President Wilson and of others in the Allied countries were subordinated to the implacable purpose of the French premier, who, "dry in soul and empty of hope", cared only to pull the talons from his enemy's claws. The fact that he alone spoke French and English interchangeably gave him a technical advantage that must have counted greatly. The British premier knew a little French; Mr. Wilson, none worth mentioning; while the other member of the Big Four, Signor Orlando, knew French only. So Clemenceau acted as interpreter between his colleagues, with consequences that can be surmised. The result was a Carthaginian peace and the sequel will be, presumably, a Pyrrhic victory. These classic allusions may be translated into the vernacular by saying that Mr. Keynes is of the opinion that the gentlemen in Paris, particularly three of them, and more especially one of them, deceived the Germans into the belief that the treaty would be based on the humanities of the Fourteen Points, and then, having got them to lay down arms, proceeded to cinch them in accord with the old-fashioned maxim of "*Vae Victis*" or "To the victor belong the spoils". The financial clauses of the treaty are considered by Mr. Keynes to be so punitive as to defeat their purpose. In this part of the book he gives much interesting information and shows an intimate knowledge of his subject, which would be more convincing if he did not allow himself to be impelled by passion into gross exaggerations. He estimates that, on the basis of the pre-Armistice engagements of the Allies, the claims against Germany should be about 10 billion dollars, a sum that it might be possible for her to pay. Instead, the Treaty exacts something like 40 billion dollars, according to his calculations. This, he says, is not only preposterous but immoral; it means "reducing Germany to servitude for a generation and degrading the lives of millions of human beings" to such an extent, among other consequences, as "to sow the decay of the whole civilized life of Europe". All this, however, must be taken as the personal opinion of a fallible individual, for, expert economist as he is, Mr. Keynes makes a blunder that warrants us in taking all he says with a large grain of salt. 'The Review', of New York, points at the fact that Mr. Keynes made a mistake in representing that \$2,500,000,000 in ships, etc., plus thirty annual payments of \$250,000,000, constitute a total of \$10,000,000,000, whereas thirty annual payments of \$250,000,000 have a present value of only \$3,850,000,000, interest being reckoned at 5%, not \$7,500,000,000 as figured by Mr. Keynes. With this serious mistake we may bracket such rhetorical flights as the statement, made apropos of inter-allied debts, that victorious France must pay her friends and Allies more than four times the indemnity that she paid in 1870. "The hand of Bismarck", says Mr. Keynes, "was light compared with that of an Ally or an Associate." Such remarks as these give a fair idea of the temper in which the book was written. It is

not judicial, even though it be granted that something of the kind was needed to awaken the world to the miserable mess created by the ill-informed individuals who undertook to settle the affairs of Europe at Paris. They were ill-informed because no three or four men living knew enough about the intricacies and complexities of economic and political geography in Europe to be able to settle satisfactorily the horrible tangle brought about by the War and its sequel of national and racial self-assertiveness. The leaders, in secret conference, did not make proper use even of the specialists whom they brought to Paris. It is no wonder that many blunders were made; and others like them would be made again if another international conference were to be called, as the 'New Republic' suggests, to correct those of the existing Treaty. The only thing left to do, in our opinion and in that of others better informed, is to use the League of Nations as an agency for modifying the incidence of the terms of the Treaty on the enemy countries, in such a way as to facilitate their rehabilitation and economic reconstruction. What is most needed is constructive purpose, without which no agreements or contracts will suffice to rebuild a shattered civilization. Mr. Keynes would have us assist Germany and Austria with an international loan of, at least, a billion dollars, but he undermines credit by saying in the same breath that if the inter-Allied loans are not cancelled, the demand for repudiation will arise. If that be so, what reason is there for believing that the enemy-countries will take a different view of a "crushing burden"? Moreover, the latest revolution in Germany, dissipating recent hopes of stable government in that country, is not likely to strengthen the confidence of investors. Mr. Keynes thinks that German exploitation of Russia should be encouraged as a means of bringing a supply of foodstuffs into the service of the world. His plainly is a Germanocentric theory of European economic life; in his anxiety to be humane and to restore the flow of trade, he seems to forget that millions of brave men died not long ago to check the aggression he is now prepared to foster. The German people are unrepentant; they even believe that their armies were not defeated in battle, but overcome by the revolution and the blockade. Sloppy sentimentality is no better than unreasoning vindictiveness. Neither is constructive. What most of us desire is to have an assurance that civilization will not soon again be endangered by the piratic onslaught of any nation and that within sane safeguards to prevent such a contingency there will be devised a plan for giving the enemy countries—for we are still at war—a chance to resume an orderly way of living and hope of regaining the goodwill of those whom they attacked so madly in the fateful years now past. We had hoped for peace and the resumption of industrial amenities long ago. Soon it will be two years since the Armistice. The disillusion has been complete; it looks at times as if the anti-social forces of the jungle were re-asserting themselves and the long and labored efforts of man to improve his status were to be frustrated by misinformation, prejudice, and petty politics.

The Ore Deposits of Mexico—II

Ore Deposits in Sedimentary Rocks. The Barreno and Ajuchitlan Mines

By S. J. LEWIS

INTRODUCTION The violent disturbances to which the Cretaceous strata were subjected, especially during the middle Tertiary period, caused extensive fracturing, nearly always in connection with some known intrusion of volcanic rock. Lime is easily dissolved by surface waters flowing for long periods in fractures; therefore at such points we have abundant alkaline waters coming in contact with magmatic waters and gases emanating from the intrusion and carrying traces of the metals. Zones of fracture thus formed in sedimentary rocks, more espe-

cially limestone, are particularly favorable to the deposition of ore. As the intrusion responsible for fracturing or loosening of the ground is generally recognizable, and as the points of contact with the limestone, or areas near the contact, are frequently highly mineralized, the term 'contact deposit' is in general use. In some respects such deposits are the most important in Mexico, constituting most of the oxidized lead, copper, and iron ores, as well as most of the zinc. The deposits of the Naica and Santa Eulalia districts (in Chihuahua), Cananea (in Sonora), Ojuelos (in Durango), Tiro General, Dolores, Paz, and San Pedro (in San Luis Potosí), Mazapil and Concepcion del Oro (in Zacatecas) are contact deposits, and have all yielded so much ore as to be of industrial importance.

While each deposit has its own special features, we can

generalize the limestone orebodies of Mexico into four groups, as follows:

Class 1. True Contact Deposits. The intrusive is well defined, and is usually a basic rock showing evidence of having cooled under cover of heavy sediments or other rocks. The sediments are usually the heavy 'blue' Cretaceous limestone, sometimes lime-shale. The two rock-members are in contact at any angle from the horizontal to the perpendicular, and the orebodies occur in lenses at or near the contact.

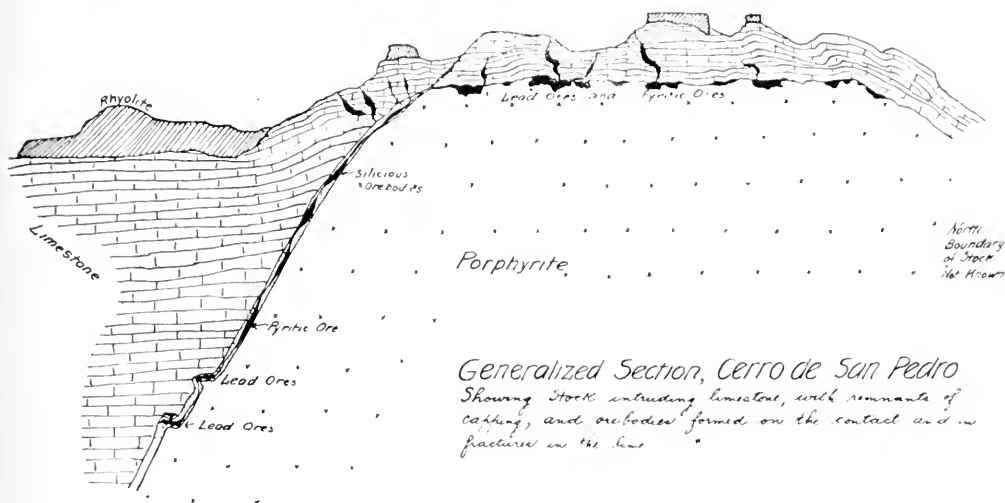

FIG. 3

cially limestone, are particularly favorable to the deposition of ore. As the intrusion responsible for fracturing or loosening of the ground is generally recognizable, and as the points of contact with the limestone, or areas near the contact, are frequently highly mineralized, the term 'contact deposit' is in general use. In some respects such deposits are the most important in Mexico, constituting most of the oxidized lead, copper, and iron ores, as well as most of the zinc. The deposits of the Naica and Santa Eulalia districts (in Chihuahua), Cananea (in Sonora), Ojuelos (in Durango), Tiro General, Dolores, Paz, and San Pedro (in San Luis Potosí), Mazapil and Concepcion del Oro (in Zacatecas) are contact deposits, and have all yielded so much ore as to be of industrial importance.

While each deposit has its own special features, we can

Class 2. Non-contact Deposits. The two principal rock-members are the same, but the igneous rock underlies the sediments more or less horizontally, and the orebodies occur in veins or fracture-zones cutting through both formations, usually at a high angle. In this class the mines are almost wholly in the overlying sediments. Such are the gold-silver deposits of El Oro, Guanajuato, Sultepec, and Taxco.

Class 3. Combination Forms. These show true contact orebodies with the limestone and igneous rock-members, but the mineralization continues into the eruptive rock. The silver mines of the Cajonero district are good illustrations.

Class 4. Limestone ore deposits in which direct connection with an igneous intrusion cannot be completed, but

which can be shown to owe their origin to deep-seated sources of mineralization. Such are the lead-iron-zinc deposits of the Monterrey district, the Mitra mountain and San Pedro Diente mines.

Most of the important mines of Mexico have been described in the technical press; my purpose is not to make a compilation of the published data relating to such deposits, but rather to illustrate principles of fracturing and circulation by examples drawn from my own observation.

BARRENO. This mine, in the centre of the Cerro de San Pedro in San Luis Potosí, is an excellent example of the true contact deposit. It has produced lead-silver-gold ores since Spanish times, and the surface pockets must have been rich, to judge from narrow stringers of gold ore still occasionally cut in the course of operations.¹¹ The San Pedro district lies about 22 km. east of the city of San Luis Potosí. The principal mines, the Victoria and associated properties, are operated by the Towne interests, the Barreno being the only independent producer of importance. The ores are lead-iron oxides and carbonates with a core of galena, and iron sulphides carrying a little lead and zinc, both classes containing sufficient silver and gold to make them desirable at the smelter. A feature of the Barreno deposit is the large tonnage of lime ore containing precious metals. This excess of lime occurs on and near the surface; with increase in depth there is a gradual but steady rise in the silica content and a corresponding drop in the lime.

The characteristic topography of the desert region is carved out of Cretaceous limestone, the 'blue' limestone of northern Mexico. The strata show great thickness, rising slowly from the flat plain of the present valley to the foot-hills. This plain was covered during early Tertiary time by several siliceous volcanic flows, of which the remains of three can still be recognized. The first and earliest is a typical rhyolite, with flow-lines and inclusions of ash; it is found with great difficulty on the slopes of the Dos Luceros hill, across from Barreno. The second is a black glassy rock with perlitic fractures; of this some is left on the Barreno hill itself as well as on the slopes going down to the valley. The last, a rock of trachytic texture, with large quartz crystals and well-marked inclusions of ash, still survives in large bodies, except where deep-seated ground movements have broken it up and facilitated removal. The almost complete erosion of the first two caps gives one an idea of the wide intervals of time that must have elapsed between the successive depositions. See Fig. 3. The last cap, the only one generally known, is locally identified as the rhyolite and survives merely as small buttes on the tops of the higher points in the district. It is from 25 to 100 m. thick, its surface being level from one peak to another.

The ore deposits are associated with an intrusive rock of quite different character, which invaded the limestone and exerted a profound influence on the topography. It is my opinion that the rhyolites existed prior to this intrusion, which was probably of Miocene age, and that

their only influence on the deposits was to afford protection from erosion and oxidation. The Barreno laccolith is a diorite-perphyrite intrusive, which pushed its way into the strata on a great scale, so that it now underlies the whole district. A local protuberance from the laccolith forms the Barreno hill, although it is nowhere visible at the surface. The topography of the buried mass has been well worked out in the course of centuries of mining operations; it is in the shape of a prismoid, or tooth, about 400 m. wide on its south face, and dipping to the south at an angle of about 55°; it is probably much longer on its east and west faces, the latter being unexplored and the former being known only in the Coeñera mine. This old mine, on the so-called east contact, shows mineralization like that of the Barreno, at a depth of 300 m. below its surface, and 500 m. below the crest of the Barreno deposit.

The north face of this intrusion stretches to an unknown distance, making a rough undulating top to the structure, going north in a band about 400 m. wide and at least 1000 m. long. The ore is found in roughnesses or pockets formed by the undulations of this underground surface, in contact with the overlying sediments; on the east and south contacts of the sloping walls of the intrusion, occurring both in the porphyrite and in the contiguous limestone; and finally, in great bodies formed at a little distance from the intrusive, entirely in the lime. This ore was deposited in immense fractures in the sediments that were opened as the intrusive pushed its way; and it has been possible to follow the fractures down for hundreds of metres, to the junction with the south contact of the intrusive. That the ores deposited in the cave-like fractures owe their origin to mineralizers coming out of the hot igneous rock-mass, there can be no doubt. The accompanying sketch (Fig. 5) shows a diagrammatic section through the ground, making clear the above-described relations. The photograph (Fig. 4) shows the Barreno hill, with some of the important fractures in the limestone, which have been worked down as far as the igneous contact probably, but which are filled with debris for some distance above it.

Three stages are distinguishable: first, deposition of large bodies of primary iron sulphides, carrying low precious-metal contents; second, a later stage of the same period, the entrance of siliceous solutions carrying lead, mercury, antimony, arsenic, zinc, and other base metals, with an increase in gold and silver. There seems to have been considerable shattering of the limestone preliminary to this stage and accompanying it. Finally came the effect of atmospheric and circulation agencies, making a period of oxidizing enrichment of the iron-sulphide ore bodies.

In the first stage, soon after the solidification of the intrusive, the hot waters and gases coming out of the latter attacked the limestone along the contact, and also passed up into the fractures in the sediments. Along the contact, crystals of iron pyrite were deposited both in the porphyrite and the limestone, apparently replacing rock-minerals in both, besides entering minute fractures in the latter. In the porphyrite, the crystals of pyrite are gen-

¹¹ By permission of R. Amilien Lacaud, President, Cia. Minera El Barreno y Anexas, Mexico, D. F.

erally scattered, in places so much as to make the rock valueless; in the limestone, all stages of replacement are found, beginning with a dark, highly siliceous rock with scattered pyrite in narrow bands, and going through every imaginable stage to a solid glistening mass that preserves perfectly the original bedding-planes. It requires

striation of lead molecules for iron molecules has been perfect. Under the microscope, two stages of change are distinguished: minute fractures, carrying mercury and other base metals, with the later products of oxidation, and chalcodonic quartz, the latter lining tiny venedets and openings.

FIG. 4. BARRENO MINE. CIRCLES SHOW OLD WORKINGS FOLLOWING FRACTURES IN THE LIMESTONE

only a glance at these beds, having all the appearance of limestone strata until a stroke of the hammer reveals the shining sulphide, to carry conviction as to the origin of these orebodies. The magmatic emanations from the intrusive, rich in iron, found favorable conditions for chemical reaction and deposition of mineral in the basins formed by local unevenness of the contact; so that in these depressions, or pockets, bodies of pyrite have been precipitated, erratic in size and shape, as well as in their metal contents, but consistently showing that they were formed by replacement of the lime molecules through reaction with acid salts of the metals.

During the second period, further movement and loosening of the ground allowed fresh solutions to enter, bringing in lead and silver; these attacked the pyrite crystals, dissolving some of the iron and depositing lead, zinc, and other metals. This continued for a long period, with consequent enrichment of the deposit. As convincing evidence of the process, we find pseudomorphs of lead after iron, that is, the crystals are of the shape and appearance of pyrite, but on breaking them they are found to be wholly of lead. The sub-

characteristic striation or grooving of the pyrite crystals that once filled them, leaving no doubt of their removal. By this action, considerable masses of ore have been made profitable, for their gold contents, that would otherwise have been too low-grade for working. The iron sulphate formed during the leaching process had a favorable in-

FIG. 5. ILLUSTRATING STRUCTURAL GEOLOGY OF THE BARRENO MINE

fluence in precipitating such gold as may have been carried in solution. Traces of oxidation are visible deep down in the deposits, along the contact-faces of the intrusion. Sinking on the south face in Barreno has reached a depth of about 300 m., and the oxidation appears to be almost as thorough as in the upper workings.

But while such secondary processes were important, a

highly significant rôle attaches to the second stage of mineralization, in which deposition from a thinner and somewhat silicious solution, coming direct from the intrusive, and evidently an end-product of the magma, did much to enrich the orebodies. That the original pyritic masses were subjected to attack by such later solutions is shown by the fact that nearly all of them, especially the larger bodies, present a perfectly uniform appearance to the eye, in section through the mass, but have a practically barren core of iron sulphide carrying no silver or gold. On breaking into a mass, the good ore will be near the outside, diminishing gradually toward the centre, where it is quite usual to find barren pyrite, presenting identically the same appearance as the ore. In most cases, stopping stops in such ground, for obvious reasons; however, exploration has been carried through the barren core in a few cases, with an improvement in gold-silver contents as the opposite surface of the mass is approached. Oxidation has left but few traces in these bodies, so that the difference in value is due, not to secondary enrichment, but to deposition from later magmatic emanations.

The foregoing is descriptive of the iron-lead orebodies found in pockets on the rolling upper surface of the intrusive; hence of the greater number in the district and the most exploited. The next most important group is that of the great caves, like Porvenir, Cinco de Mayo, and Santa Clara, in which for centuries stoping of lime-rock containing gold and silver has been profitable. Outcropping at the surface, and going down as immense fractures through the strata to the intrusive, oxidation has played the chief part in the transformation of the primary iron sulphide. The rock is to all appearance thoroughly oxidized and quite free from pyrite. It carries abundant sulphides, however, as shown by concentration either on tables or on the batea, with lead, zinc, and manganese as carbonates and oxides. That the enrichment originally came from mineralizers connected with the eruptive, is indicated by the frequent occurrence of rich streaks of gold-silver ore, two or three inches wide, running down vertically without evidence of fracturing, the value gradually diminishing on both sides till barren limestone is reached. (See Fig 6.) The total width of impregnation is usually from one to two metres in the case of a rich streak, the whole appearing like a zone of impregnation. The same is true where the fracture is visible; in both cases, the enrichment has begun along a line of weakness or a channel of circulation, and worked its way into the limestone as far as it could, as in some of the instances noted by Irving.¹²

The rich streaks in these caves have been stoped very deep, and the old holes have been in bad condition during modern times; it is therefore impossible to follow them quite to their point of connection with the intrusive; however, they have been explored to within a few metres of it, so that the indications are that the connection existed during periods of mineralization. Evidently every crack

in the limestone became a centre from which gases and solutions worked their way into the strata until their strength was spent, making the orebodies described, and forming blanket deposits of lead-iron ore by selective action on certain strata. (See Fig. 7.) There is no difference to the eye, in these limestone orebodies, between profitable ore and rock too low-grade to be classed as such; the difference is simply that the former is broken out from channels of mineralization, and the latter is at a distance from them.

Finally, we have the contact bodies on the inclined faces of the intrusion. On the south incline, which for many years was spoken of as the 'break', the heavy ground-movements, with the strong oxidation due to free circulation, has caused the whole structure to assume the appearance of a fault-fracture or vein-fissure, with thick gouge and occasional lenses of ore. The hanging wall is limestone, the foot-wall porphyrite. Silver and gold are found in both walls and in the crushed material between. Wherever the generally smooth face of this inclined contact has a local wrinkle in it, forming a little shelf, small bodies of rich lead-silver ores are found, always well oxidized, and containing gold and silver. In general, it may be said of this contact that the most generous deposition of silver and gold was accompanied by the highest proportion of silica, when we speak of ores in the porphyrite. In the limestone ores, the richest precious-metal ore was found at the surface, accompanied by high lime-content and little silica.

Without going into further detail in the study of this interesting deposit, we see from the foregoing that deposition directly from magmatic solutions played a chief part at the beginning; that subsequent deposition from solutions of similar origin, now grown extremely silicious and carrying gold and silver as well as the other common metals, was of great importance in enriching them; and that finally the circulation of surface-waters has had an enriching and oxidizing effect wherever they could get into the orebodies; a highly complicated interchange of elements, which to some extent mineralized the whole Barreno hill, and made ore in and near the circulation channels.

The great fact to which all study of this district points as the basis of mineralization is the fracturing due to the intrusion, from which resulted a complex system of channels in which waters could circulate, and a supply of magmatic waters to carry the minerals.

AJUCHITLAN. Another good example of the true contact deposit in Mexico is afforded by the Ajuchitlan mine in the State of Queretaro; with the interesting difference that the orebodies occur in lime-shale, like that of El Oro, instead of the blue limestone of the Cerro de San Pedro. Like these latter deposits, the Ajuchitlan mines have three rock-members: the country shale, in which the deposits are found; an intrusion of igneous rock, responsible for the deposits; and a cap of andesite, also antedating the intrusion and protecting the ore.

The Ajuchitlan mines¹³ are about 20 km. east of the city of Queretaro and have been worked from the earliest

¹²J. D. Irving, 'Replacement Orebodies', in 'Economic Geology', Vol. VI, 1911.

days, the old Santo Tomas mine high on the outcrop, just under the cap, belonging to Spanish times. The formation is black and gray shale, clearly early Cretaceous. The shale rests unconformably on a heavy blue

limestone, and fossil oysters of Lower Cretaceous type are found in the debris below. A good exposure of the stratigraphy occurs in an arroyo on the Bernal side of the Ajuchitlan mountain. The blue limestone is cer-

limestone, and fossil oysters of Lower Cretaceous type are found in the debris below. A good exposure of the stratigraphy occurs in an arroyo on the Bernal side of the Ajuchitlan mountain. The blue limestone is cer-

¹²With acknowledgments to C. Crowell, President, the Ajuchitlan Mining & Milling Co., Monterrey, N. L.

El Oro cap, covers the higher parts of the cliffs and forms a level rim-rock around the north-eastern horizon. (See Fig. 8.) All the features of the old topography are visible near the mines: the Cretaceous valleys and peaks covered with the andesite, the highly enriched ore deposits outcropping just under it, and the white intrusive,

of Miocene age, that originated the mineral. One of the difficult features of exploration underground has been the necessity of driving through a Cretaceous arroyo filled by waste from the erosion of that period, and later covered by the andesite.

The igneous intrusion, whose association with the ore deposits is so close as to leave no doubt as to origin of the latter (Fig. 8), is a white close-grained porphyrite, with sparse quartz crystals speckling it, and is locally known as 'rhyolite'. It is of special interest on account of the way it has penetrated the shale, shooting out tongue-like masses on one side, which have become cores of mineralization. The centre of vulcanism for this whole area, from which this 'rhyolite' has come, is probably the tooth-like butte visible from the railway, known as the Pico de Bernal, which pushed its way through the formation, lifting shale and cap and facilitating the removal of the latter from all the section except the tops of the hills. The soft shale wore away rapidly, so that the Pico is bare to its base. The disturbance of the shale, both in bedding and composition, near the Pico, twisted it in every direction and caused great chemical alteration. The normal black color of the sediments is changed to red, buff, and purple where the sharp tooth protrudes through them, making a striking feature of the landscape. The mine lies about 5 km. west, on the opposite side of the Ajuchitlan mountain. The material of the Pico is in every way the same as that of the mine intrusive, and the inference seems to be warranted that they are both local excrecences from an immense underground mass. The introduction of this mass into the shale fractured it violently; in the case of the Pico, the mass came to the surface and everything around it has been eroded; in the case of the mine intrusive, it pushed its way up to the cap and spread out or mushroomed under it; the cap protected the deposits from erosion, so that the chemical effects of the intrusion on the shale were saved for later exploitation.

Reference to Fig. 8 will show that much influence was exercised by small tongues of porphyrite pushed out from the mass and brecciating the shale near-by. This broken zone was saturated with vapors and waters emanating from the intrusive, and a little mineralization took place; but the principal effect seems to have been produced about 25 m. away from the intrusive, in the mineralization of certain shale strata, always on one side of the rock protrusions. The intrusive mass itself is about 300 m. wide, so far as known, but it may be much more. While the fact of the orebodies occurring more or less uniformly at this distance from the intrusive may be due to selective action, it seems more likely that difference of temperature at a distance from the hot intrusive was the deciding factor. The period of primary mineralization seems to have been brief and uncomplicated, and to have left irregular masses of quartz-breccia, from one to eight metres thick, in lenticular bodies a few metres removed from the tongues of porphyrite, and each lens practically independent of the next. Small rich pockets of iodides, bromides, and chlorides have been found, usually in the upper workings near the cap. The ore, in which the

value is equally divided between gold and silver, is an extremely hard silicious replacement of the finely-crushed shale ground up during the fracturing. These fragments, cemented together by the silicious solutions that brought in the gold and silver, form a characteristic breccia, sharp-pointed and triangular, with little indication of up and down movement of the walls.

The end of the period of primary mineralization was accompanied by settling and cross-faulting of the recently formed quartz bodies. This led to typical fault-enrichment of the kind that forms such a marked feature of the El Oro deposits, that is, the neighborhood of a fault-fracture invariably shows enrichment of the quartz. Evidently the new cross-channels served for the movement of fresh later solutions carrying additional mineral, as well as for the entrance of surface-waters to do the work of secondary enrichment. Oxidation has been so thorough that no sulphides occur in the deposits at all; they are merely silicified shale fragments with a little silver and gold in them.

It will be evident from the foregoing that the whole mineralization is due to the intrusion and to the after-effects of re-enrichment. In planning exploration, therefore, the central feature has been the intrusive, and the miner has sought to follow it, finding lens after lens, usually at 25 to 30 m. from the intrusive. The similarity in general features between these deposits and those of the Cerro de San Pedro is striking. On structural grounds, the two deposits go at once into the same class. The difference is mainly that of the country-rock in which the mineralization took place; in the case of the limestone we get a lead-zinc-iron deposit low in the precious metals; in the case of the shale we get gold-silver ores with practically no impurity. This condition is probably owing more to the difference in chemical reaction of the rock than to any other one factor. The outstanding feature is again the fracturing of the shale and the entrance of solutions from the intrusive into the channels.

These two examples show every feature of a contact deposit, including the protecting cap. It is more usual to find contact deposits with some of the features lacking, but a complete history of them can be built up by a study of several mines in the same district. Of this nature are the interesting iron deposits of Michoacan and Colima, near the West Coast. The showings near Coalcoman are characteristic of this class. The limestone sediments, which are extensive have been disturbed by late intrusives, generally the monzonite-granite that is found in many copper districts of this region; it grades occasionally and locally into a fine-grained diorite. The upper surfaces of the monzonite masses, in contact with the lime, are frequently enriched by copper and iron; the former occurring as a flat blanket lying directly on the granite, usually but a metre or less in thickness, and showing extensive alteration to carbonates and oxides. Lying on top of the copper is the iron, a cap 50 to 100 ft. thick, and showing pure oxides with 60% iron. Careful study of the rocks shows that the mineralization is the result of replacement of the limestone by iron, followed by secondary action. In many cases, the unaltered lime-

stone lies on top of the iron cap, so that the series is complete as regards the flat contact type.

Other deposits nearby show the immense fractures across the limestone strata that form such a marked feature of the Cerro de San Pedro; these contain copper, zinc, and iron, practically amoxidized a few metres from the surface, and with fine secondary silicate minerals,

show the vertical fractures in the limestone without the gossan; both disclose the granite intrusive. It is evident that originally all members of the series existed, the granite intruding the limestone and forming the fractures, and the mineral solutions proceeding out of the granite to circulate in the limestone so as to make ore. See Fig. 9.

FIG. 9. SECTION ON CONTACT OREBODIES IN SOUTH-EASTERN JALISCO

such as are usually found at contacts. The limestone is underlain at considerable depth by the granite, the contact being buried; so that by grouping deposits that lie near each other and all in the same general horizon, we get a composite structure exhibiting nearly all the features of the Cerro de San Pedro. The Amoles mines show an extensive boss of monzonite, crowned with thick and pure iron gossan, with a copper blanket below the iron and unaltered lime above it; other points near-by

Nearer to San Luis Potosi, at Charcas, there are contact deposits that in all essential features are identical with those of the Cerro de San Pedro. The country-rock is the same blue limestone as at San Luis, which has been intruded by dike-like tongues of porphyryite. Microscopic examination of this igneous rock shows its likeness to the Barreno intrusive, the large phenocrysts of quartz and feldspar being especially clear; the difference lies in the lack of mica in the Charcas rock. The orebodies are

found on the nearly vertical contacts of these dike-like masses with the limestone, occurring sometimes in one, sometimes in the other; seldom in both at the same point. In the Tiro General mine, the largest in the district, mineralization seems to have formed immense bodies of pyritic ores with most of the base metals, very much as the same minerals were deposited at Barreno. The present highly oxidized condition is the result of later oxidation. Both in the Tiro and in smaller mines of the district, fracturing of the limestone by the intrusion of the porphyrite has evidently made the ores, as circulation has taken place on the contacts themselves. The inference is that immense blocks of limestone were floated on the intrusive mass until the latter cooled.

The series of caps that were important at San Pedro in protecting the deposits from surficial agencies are here conspicuous by their absence. It would seem that these intrusions came into the district coincidentally with that of San Pedro, fracturing the strata and shearing them, and solidifying in sheet-like masses which stand vertically. Owing to absence of cap, surface destruction was thorough, and the upper portions of the series were completely removed, making about 2000 ft. of rock that has been eroded. Thus we find no irregular cave-like orebodies in the limestone, except a few high up in the topography; nor are there horizontal contact bodies on the upper surface of the intrusive; but nearly vertical vein-like bodies accompanying the dikes. What is left at Chareas is the lower portion or roots of the deposits, corresponding to the deeply buried part, perhaps, of the San Pedro formation.

An interesting feature of this Chareas camp is the effect of the heavy fracturing on both sediments and igneous rocks at a little distance from the centre of movement. Narrow but persistent fractures have been made, in which circulation has deposited ores of a type totally different from those of the contact bodies; but the origin of these different ores, viewing the district as a whole, is clearly in the same intrusions that made the great contact bodies.

A fine example of the true contact orebody, in which the metals above mentioned do not appear at all, is found in the Santa Maria antimony mines on the Zoyatal mountain in Queretaro, 90 km. north of Bernal station on the National railway. The ores are exclusively antimony of great purity, without lead, iron, zinc, arsenic, silver, or gold. For this reason they are of special interest as regards the origin of the mineral.¹⁴

There are three rock-members in the formation, as shown in Fig. 9. The original surface was of lime-shale in thin laminae, the whole probably 1000 ft. thick. These rest unconformably on the Lower Cretaceous limestone, which is from 300 to 1000 ft. thick. Below this and intruding into it, is a laccolith of dark, heavy, finely granular rock of ferro-magnesian type, probably a gabbro, which has pushed its way up through the other two members, destroying the shale locally and carrying the lime-

stone high above them to form the hill. The small tongues of eruptive proceeding out of the main mass form narrow, almost vertical, pockets having a limestone-gabbro contact, in which the limestone is replaced by the sulphide of antimony. The mineral is never found in the eruptive, and mineralization ceases as soon as the limestone ends. Quite clearly, deposition took place by replacement of the lime. The antimony occurs as practically pure sulphide in fine crystals, accompanied by calcite and gypsum, also well crystallized. One would suppose that the antimony was deposited from alkaline solutions, and there is room for study to determine why it came down without admixture of other metals.

Oxidation has been extensive but not thorough, nearly all the oxidized ore showing a core of unaltered sulphide. The principal orebodies are found at a distance of from 35 to 50 m. above the contact, except in the small vertical contacts like the Colmena; they occur either as replacements of the limestone, or in built-up aggregates of fine crystals filling openings made by ground movements. Crystallization is just as perfect in the case of the solid dense limestone where there is no evidence of opening, the crystals occurring as beautifully branching growths beginning at a circulation channel and growing into the texture of the limestone for a distance of a metre or more. In such cases, the crystals are generally pure sulphides; many cases are seen, however, where these branching crystals are almost entirely oxidized in place; they are fine examples of replacement from mineral-bearing solutions.

In general, the occurrence of ore is like that in lead mines of the contact type; the orebodies are blanket deposits from 50 cm. to 3 m. thick, replacing one or more nearly horizontal strata, with especially good enrichment at points where vertical cross-fracturing has taken place; in which case the ore continues into the fractures and in favorable cases forms parallel blankets by spreading out into adjoining strata.

That the mineralization of these deposits is due to emanations from the laccolith, rising through narrow and perhaps obliterated channels into the limestone horizon, seems evident. It is interesting to compare the deposits with the Ajuchitlan mines, noting the resemblance in deposition at a short distance from the intrusion, the resemblance also in shape of the protrusions from the igneous mass, and the striking difference in mineralization. That in the one case the intrusive is a nearly white, highly acid rock, yielding gold-silver mineralization, and in the other is a dark, ferro-magnesian, basic rock, yielding antimony without a trace of gold or silver, is certainly suggestive.

AMERICAN MAGNESITE is purer than the Austrian material, which, by virtue of its content of a small amount of iron in just the proper amount, is better suited by nature for use in the steel industry. However, the early difficulties encountered in the use of domestic material have been quite satisfactorily overcome. The lack of the desired amount of iron in American magnesite is met by adding iron synthetically.

Mine-Sampling

By WILLIAM HUFF WAGNER

INTRODUCTION. The methods of taking samples and the system of keeping stope and assay-maps described in this article are applicable especially to the mines of the Butte district. While the methods were devised by the engi-

In the mining of copper ore in the Butte district, sampling is becoming of more significance every day, and all the operating companies are gradually giving proper recognition to this branch of technical practice. The importance of the subject is being driven home more forcibly as the mines attain greater depth. With depth, all mining problems become increasingly difficult and costly, and consequently the need for economy in production enters more and more into the conduct of operations.

The operating officials appreciate the higher cost of mining the ore cleanly, and the lower cost per ton of a product containing a larger admixture of waste, but they realize that there is a mean point at which the maximum profit to the enterprise is obtainable. The average foreman or shift-boss, however, seldom understands this relation. To many of the latter higher tonnage per man-shift invariably means low costs, and this false conception leads to the breaking of con-

neers of the North Butte Mining Co. to fit the conditions existing in a particular group of mines, they can be modified readily to apply to deposits worked by other methods than those in vogue at Butte.

The success of any mining operation depends in large part on the accurate knowledge of the composition and metallic contents of the material in the faces exposed in the mine, as well as of the ore broken for shipment or local treatment. This knowledge is of especial importance to a company that sells its ore to a custom smelter; in this case it is frequently necessary to maintain a specified grade or be penalized, and this latter may represent the margin between a profit and a loss.

FIG. 2. TYPICAL STOPE-SECTION

siderable wall-rock along with the vein-material; it causes the failure to apply selective mining (separate blasting to the narrow veins, and the neglect to sort ore, all of which results in an excessive proportion of worthless rock being hoisted to surface. The grade of ore shipped is bound to suffer, and the final and most important cost, that is, the cost per pound of copper, will rise, although the cost per ton of ore may fall somewhat.

SAMPLERS AND THEIR EQUIPMENT. Correct sampling is one of the most difficult of mine operations, and since its bearing on the grade of ore is vital it behooves a company to select its samplers carefully. These men need not necessarily be technical men, but such generally are preferred. The men chosen for samplers must be alert and wide-awake, they must have a good knowledge of mining and of the rocks and ores to be sampled, and, above all, they must be thoroughly reliable and honest. It is often difficult to get men for this work because it is hard unpleasant manual labor as viewed by most men in the mines. They should be on a salary and be directly under the chief engineer or the geologist, preferably the latter, as is the case in the North Butte organization. Their working outfit consists of a sample-pick one foot long, a supply of twine and cloth sacks, small paper pads, pencils, one 75-ft. metallic tape, and one 2-ft. Lufkin box-wood angle-rule. A sample taken by channeling with a moil and single-hand hammer is acknowledged to be more accurate than a sample cut with a hand-pick and caught in a bag, but the needed paraphernalia is bulky and awkward to carry. Further, I believe that, considering the small amount of material cut, we can by careful work with the sample-pick cut a representative sample.

SAMPLING IN STOPES. Our scheme of sampling is as follows: The ore is sampled by the regular samplers before being mined; samples are taken generally in alternate sets as advance is made along each floor, or, in special cases, at closer intervals if the grade of the ore is low or the vein irregular. The samplers make a custom of taking grab-samples from the broken ore in the stopes and similar samples from the cars on the levels, using these to check the samples from the faces, and to see how cleanly the ore is being broken and sorted. The ore is sampled at the mouth of each chute by one of the motor-crew, a handful being grabbed from each car as it is being loaded. This sample is placed in a box close to the chute. The same man again samples the ore at the station, by taking a handful from each car as it is dumped into the skip-pocket. This goes into the general sample-box at the station. The process is repeated at the train as the railroad cars are loaded from the surface-bins preparatory to haulage to the smelter. This last sample is taken by one of the loaders, all the car-samples being then combined to form one train-sample.

To secure a representative grab-sample from the motor-crews is one of the most difficult tasks we face, because these men do not appreciate the importance of careful sampling and therefore slight the work. They have been known to take the sample representing an entire shift

from one car; they will even salt the sample purposely; or innocently grab the richer line from the top of the car. The problem is largely one of careful education of these men, and only by constant attention can these difficulties be overcome.

DEVELOPMENT-SAMPLING. In the development of new country by cross-cuts, drifts, and raises, special samples and advance measurements are taken weekly on 'development day' by the regular samplers. In addition, when the vein is irregular, or the grade of the ore is low, or new features appear, the faces are sampled after each round. In drifts, the shovelers sample the cars while loading by throwing a handful from each into a box supplied for that purpose. All the samples from development work are assayed for copper, silver, and gold, and sometimes for zinc, whereas the samples from the stopes are assayed for copper only. Detailed records are kept of all development-assays and from these the value of the ore-reserves is calculated.

METHOD OF TAKING SAMPLES. The usual method of sampling as applied to all development and stope-work is as follows: In the case of narrow veins (less than one set wide), separate samples of the vein and wall-rock are taken. If there are foot-wall and hanging-wall streaks with a horse of waste between, separate samples of all three are taken. For a full face of ore of uniform grade, one sample straight across the face will suffice; but if one part of the vein is richer than another, it is better to sample the two portions separately, at the same time noting and recording the respective widths. In cross-cuts and raises, both the faces of ore exposed are sampled, their average assay being accepted as the correct value of the ore.

In order to reduce the possible error to a minimum, if the face to be sampled is 8 to 10 ft. wide, the distance should be divided into two equal parts and two samples cut. If wider still, more samples should be cut, each one being confined to a width of four feet. The face to be sampled is first brushed and cleaned thoroughly; then the samples are taken by cutting a groove 2 to 4 in. wide and $1\frac{1}{2}$ to 2 in. deep, using the sample-pick along a line at right angles to the strike and dip of the vein, catching the sample either in the hand or directly in the bag, which is held open by a wire-hoop. The finished sample weighs from 3 to 5 lb., its size depending on the width sampled.

The regular samplers deliver all their bags to the station-tender as they leave the mine at 2:45 p.m., while the individual chute and station-samples are delivered to him by the various motor-men at the end of the shift. All samples are taken to the surface immediately, where they are picked up by the motor-man and delivered to the assay-office. There the motor-man finds an order for empty sample-boxes left by one of the samplers, and, securing the requisite number, he takes them to the collar of the shaft, whence they are lowered to the levels as specified on the order.

All the stope samples are identified by means of paper tags giving complete information as to date, chute-num-

ber, floor, number of sets east or west from the chute, width sampled, and position on the face; samples taken by the motor-crews are tagged as to date, chute or station number, and the shift on which they were taken. These

latter samples are marked by the shift-boss as he goes through his 'beat'.

CRUSHING AND ASSAVING. At the assay-office each sample is put into an iron pan, to which the tag is secured, and which is placed immediately in the drying-ovens. The following morning the samples, being dry,

are crushed, mixed and put down with a Brinlon riffle in the usual manner. They are next ground in a disc pulverizer and forwarded in small iron pans to the laboratory for immediate assay.

The copper content in stope samples is generally obtained by the colorimetric scheme, whereas on all development, check, and special samples titration by the cyanide method is used. The results, entered on regular report sheets by the assayer, are delivered to the samplers' office by 3 p.m. There the samplers transfer the results to the shift boss's books, shown in Fig. 1, and plot the stope and development assays on the assay maps. Fig. 2 shows a typical stope map and Fig. 3 illustrates the symbols used.

ASSAY AND STOPE MAPS. The assay maps, drawn on a scale of 1 in. to 40 ft., seem to meet our demands and give the company an absolutely correct and detailed record of its workings. They are kept up to date daily by the samplers. The latter can, by coming out of the mine at 2:45 p.m., enter the results in the shift boss's books and make the necessary entries on the maps by 4:30 p.m., when the whistle blows. These maps are kept on swinging wall-panels (Fig. 4) in the engineer's office at the mine and are always accessible to the bosses or mine officials. On the same maps are placed vertical sections, always up to date, of development raises, showing the structural geology, as well as the progress. An intelligent boss at any time by means of these maps can get the necessary data as to a raise without hunting for the geologist.

In making reports to the head office, these maps are used to good advantage. At the end of each quarterly period the ground excavated in the stopes and drifts is outlined in black, dated, and colored with dilute yellow ink. The maps are then photographed to a reduced scale

of about ¾ in. to 100 ft., the yellow ink causing the excavated areas to appear darker than the virgin ground in the photograph. The photographs are then painted in different colors to indicate the ore-reserves and the work done by quarters for the current year. The ore-reserves are calculated for each stope and the calculations placed on the back of the picture for that stope. One set of pictures is sent to the head office and a duplicate set kept at the mine affording a permanent progress record.

FIG. 4. ASSAY-MAP WALL-PANELS

Discrepancies in Weighing Bullion

By HARRY R. S. WILKES

*Differences between the mine weights of gold bars and those of the same bars, recorded by the buyers in England, before melting, often occur; and further differences, after melting, generally are recorded. This is, of course, well known, as is also the fact that these differences are apparently all in favor of the buyers.

The sales account usually gives three records of weights, namely: mine weight; London weight before melting; and London weight after melting.

It is with the differences between these that I propose to deal.

There are two general methods in use on the Rand for pouring gold:

(A) Pouring without slag, after skimming, and

(B) Pouring under a slag cover. The former is most suitably employed in dealing with gold of high fineness, the latter when melting gold containing much base metal.

The correct condition for pouring gold is that it be at as low a temperature as is compatible with slow pouring. The estimation of such a temperature is a matter of considerable judgment, and may be said to enter the province of the expert; at any rate the ability is only to be acquired by long and constant practice. It often happens that this condition does not obtain, because of the fear of having the metal freeze before pouring is completed. It is customary with both the methods after the metal has set, and while still hot, to quench it in water, or weak acid; in water to remove the slag and in weak acid to clean the surface before scrubbing.

The centre of the bar is the last to set, and after setting a further contraction takes place until the bar is comparatively cool. Hence a cavity is formed in the centre due to the rigidity of the rapidly cooled sides. As this cavity forms, a partial vacuum is set up, which draws into it through the centre of the top of the bar, that is, the line of least resistance, a filling; in case of method (A), of water; and of method (B), of slag, with sometimes a little water. Usually the aperture connecting with the cavity is a small one, either a fine crack or a pin hole.

In method (A) the cavity is filled with water or weak acid, and differences between local and home weights, before melting, often occur. These vary considerably. Since in some bars the apertures are so small that evaporation on the voyage to England is incomplete, and also some bars are subjected to more or less heat to dry the surface before weighing. If the bars poured by method (A) are thoroughly dried, no differences between local and 'before melting' London weights should occur. When they do, they are due to weighing and clerical errors. Owing to the lengthy war period, during which accounts have not been received, precise information of differences are not available.

For many years it has been my regular practice, when

the bar has been cleaned, to place it on the hot cover of the smelting furnace for about twenty minutes. Within fifteen minutes if the cover is hot enough the contained water is expelled with some force, in jets of water or steam through the small apertures of entrance, and only when steam ceases to issue from these holes is the bar considered dry for weighing. On two occasions, it was possible, with cold bars, by injecting air with a blow-pipe, to release the contained water, which amounted in one case to 10 cc. and in the other to 15 cc. These quantities will be referred to later.

For some time after the bar has set after pouring by method (B) and while it is still contracting, the slag cover remains in a molten state, and is thus easily drawn into the cavity. If the bar is quenched in water to remove the slag, while still very hot, a little water is often drawn in as well, and completes the filling of the cavity. Of 230 consecutive bars poured by this method only 39 showed a loss on reaching London, and the average difference between local and 'before melting' London weights was only 0.037 oz. This loss, I suggest, was due to evaporation of the water filling, during the voyage, that is, the water which entered the cavity after the slag had been removed from the bar. The slag which had already partly filled the cavity of course remained unchanged during transport. Weights 'after melting' are always considerably less than those before melting, and it is sometimes assumed that this loss is solely due to the refining by oxidation during the re-melt; doubtless there is some such loss, but that it accounts for the total difference is open to serious question.

Of 22 consecutive bars poured by method (B), the average difference between the fineness estimated by assay at the mine, and that estimated by the buyers, was 0.07 millienes, the buyer's assay being the higher. This difference on the 22 bars amounted to 1.5 oz. in favor of the sellers. The fine gold allowed for by the buyers was, however, 16.5 oz. less than the mine estimation owing to the loss of weight in re-melting, nearly all of which may be fairly assumed to have been due to encased slag. Dip samples being taken in London, for assay, the increased value of 0.07 millienes in the London assays most likely represented the amount due to refining during the re-melt, which in the case of the 22 bars under consideration amounted to a total loss of weight of 1.5 oz. In support of this may be presented the fact that the weight of slag sufficient to displace 10 cc. of water is approximately 0.76 oz., and as above stated it was found possible to release 10 and 15 cc. respectively from two bars. The weights taken for assay by the buyers, and the net scrapings, are, or should be, included in the final weight of the bar at home. From the foregoing I am led to the conclusion that an apparent discrepancy only exists between the values of the gold estimated here and those received from the buyers.

IN ADOPTING the steel helmet as a head protection the miners in the Picher zinc mining district in Oklahoma declare "Accidents take money out of the pay envelope".

*Abstract from Journal of C. M. & M. Society of South Africa.

A Modification of Horwood's Process for the Treatment of Copper-Zinc Ores

By H. L. HAZEN

The separation of the sulphides of copper from sphalerite is a metallurgical problem that has been solved successfully in comparatively few instances. Perhaps the main reason for the lack of success has been the difficulty in maintaining constant the conditions found necessary for the production of a high-grade zinc concentrate containing little copper and a copper concentrate sufficiently low in zinc to escape the penalty imposed by the purchasing smelter. Preferential flotation methods still held out a promise, but most of these methods require a delicate control of conditions that is difficult to maintain in a mill. Another method that has received considerable attention is Horwood's, which was evolved for the separation of lead sulphide from the sulphide of zinc.

As is well known, Horwood's method consists essentially of:

First. Extraction of the sulphides from the ore in a mixed concentrate.

Second. Giving the concentrate a quick roast at a temperature ranging from 300° to 500°C. for the purpose of forming an oxide film on all the minerals except the sulphide of zinc.

Third. Re-treatment of the roasted material by flotation, the sphalerite concentrating out in a high-grade product, leaving the major portion of the other minerals in the tailing.

When applied to copper-zinc ores this method has been successful for short periods of time, a high-grade zinc concentrate and a copper concentrate low in zinc being obtained. In continuous operations, however, it has not been found possible to keep constant the required temperature in the roasting operation and the resultant flotation products could not be marketed. To illustrate: if the temperature in the furnace became too high, the sulphide of zinc was superficially oxidized and would not respond to the subsequent flotation treatment. If sulphuric acid was used to dissolve this zinc oxide off the sphalerite prior to flotation, the acid also cleaned the copper sulphides, after which flotation gave a copper-zinc concentrate and the mill-man was no better off than he was before the roast.

For the purpose of eliminating the necessity for accurate and careful control of the roasting conditions and in order always to be certain of obtaining a copper concentrate sufficiently low in zinc to escape penalty and a high-grade zinc concentrate, the following modification of Horwood's method is suggested.

First. Concentrate the ore into a mixed concentrate of all the desired minerals.

Second. Roast this bulk concentrate at a temperature in excess of 300°C. for a sufficient time to oxidize completely the copper sulphides.

Third. Transfer the roasted material to suitable equipment and dissolve out the copper sulphate formed during the roast with water sufficiently acidulated with sulphuric acid to remove whatever zinc oxide has formed on the sphalerite. The copper can be readily recovered from solution by precipitation on iron.

Fourth. Treat the residue by flotation for the purpose of extracting the sphalerite in a high-grade zinc concentrate. The flotation tailing will be a concentrate of copper containing little zinc.

The basis for this suggestion is a number of tests made on various complex base-metal ores. In every case the test was carried out in the same manner and the results obtained with each ore were so similar that the details of two of the tests made on ores from different localities will be sufficient to illustrate the results that could be expected from this treatment.

Sufficient ore was concentrated by flotation to give a mixed concentrate weighing 500 grammes. This concentrate was then placed in a roasting-dish in a muffle, which was heated until the copper sulphides were well ignited, the temperature reached being 300°C. All external heat was then removed from under the muffle and the concentrate, which was self-combustible, allowed to burn freely in a good supply of air and rabbled frequently. The temperature of the roast rose rapidly to a maximum of 470° and maintained itself there for about an hour, after which it fell gradually as the combustion neared completion. The calcine was agitated for 30 minutes with water acidulated with four pounds of sulphuric acid per

Table 1. Details of Test Made on First Sample of Ore

Product	Weight %	Assay						Distribution

(copper concentrate)	21.98	5.37	2.70	2.92	1.20	6.92	60.00	21.43	30.26	34.78	55.86	1.74	75.80
In solution								none	none	37.50	none	4.60	7.52

tion of calcine, the pulp filtered and the dissolved copper recovered from the effluent by precipitation on scrap-iron. The residue was transferred to a flotation machine and the sphalerite concentrated out, leaving a tailing commercially free of zinc.

The results of these tests are shown in the accompanying data. See Table 1.

As shown in the preceding table, 37.50% of the copper content of the ore was recovered as cement copper and 46.20% more obtained in a product sufficiently low in zinc to escape penalty by a smelter, making a total extraction of 83.7% of the copper in the ore. The zinc concentrate assayed 54.1% zinc and contained 87.6% of the zinc in the ore.

As a matter of interest it may be stated that another test made on the calcine showed that 80% of the copper in the ore could have been dissolved had sufficient acid been used after the roast. It will be noticed that the copper concentrate, after the flotation of the zinc, assayed slightly less than 3% copper, but under the marketing conditions peculiar to this ore it was decided that a larger profit could be made by marketing this product direct than by dissolving out the copper with acid and selling cement copper.

The results obtained in this test could have been improved both by better control in the first flotation treatment (for instance, most of the iron could have been dropped out without serious loss in the copper extraction) and by better control of the subsequent roast, as the amount of zinc oxidized and subsequently lost in solution depends upon the temperature of the roast.

Table 2. Details of Test Made on Second Sample of Ore

Product	Weight %	Assay		Distribution	
		Cu %	Zn %	Cu %	Zn %
Original ore	100.00	3.11	10.79	100.00	100.00
Bulk-flotation concentrate	48.76	6.03	20.77	94.64	94.88
Flotation zinc concentrate after roast	10.56	1.68	55.81	5.79	54.59
Flotation middling after roast	6.98	5.11	36.19	11.58	23.45
Flotation tailing after roast (copper concentrate)	19.53	6.39	4.28	40.19	7.78
In solution				37.92	8.53

It is seen in the above table that 37.6% of the copper in the ore was recovered as cement copper and 40.1% more obtained in a product low in zinc, making a total extraction of 77.7% of the copper. The zinc concentrate assayed 55.8% zinc and contained 54.6% of the zinc in the ore. In addition, a further recovery of copper concentrate and zinc concentrate would be obtained from the middling when it returned, in the normal course of milling, to the roughing-cells for re-treatment.

Probably the most serious objection to this method would be the loss of dissolved zinc, and the higher the temperature reached in the roast the greater would be the amount of zinc oxidized and dissolved from the calcine. The extraction of a portion of the copper as sulphate in solution might or might not be a drawback on account of the cost of the operation, and this would depend upon whether the zinc tailing is to be marketed as a copper concentrate or whether it would be preferable

in the circumstances to dissolve out the maximum possible amount of copper with acid and market it as cement copper.

The great advantage that it is believed this modified treatment would have over Horwood's method in the concentration of copper-zinc ores is that no great delicacy of control would be needed for the production of a high-grade zinc concentrate and a salable copper product. No matter to what temperature the roast should be taken, a day's run would not be spoiled by a kinky copper concentrate; it would merely mean that more acid must be used to clean the sphalerite and that more zinc would be lost in solution, but the copper and zinc concentrates would remain of a uniform grade.

THE PRODUCTION OF COPPER in the United States in 1919 was markedly smaller than in 1918, according to preliminary figures and estimates collected by R. S. Butler, of the U. S. Geological Survey, from all plants that make blister copper from domestic ores or that produce refined copper. At an average price of about 19 cents per pound, the output for 1919 had a value of \$243,000,000, as against \$471,000,000 for 1918. The figures showing the smelter production from domestic ores represent the actual output of most of the companies for the first 11 months of the year and the estimated output for December. A few companies gave no figures for November, but furnished estimates of the combined output of November and December. The production of blister and Lake copper from domestic ores was 1,278,000,000 lb. in 1919, against 1,908,000,000 lb. in 1918 and 1,224,000,000 lb. in 1913.

THE following are the principal taxes levied by the government of Greece on mines and mineral products: (1) an annual acreage tax of \$0.0193 per stremma (1 stremma equals about one-fourth acre), assessed on the surficial area worked; (2) a tax of 5% on the clear profits of the mines, which is to be ascertained by deducting the operating costs from the amount received from the sale of minerals (by a recent law this tax has been increased to 10%); (3) on the net profits a further tax of 1½% is levied in favor of the miners' fund, which is set aside by the Government to be used with other moneys in payment of accident claims among workers; (4) a tax depending on average profits and rental is also assessed, augmented by a tax on the amount of stamped paper used by the mines.

THE DEMAND FOR CHROMITE during the War led the U. S. Geological Survey to make special examinations of deposits of this mineral. A statement on the results of one of these examinations is contained in a 'Preliminary Report on the Chromite of Kenai Peninsula, Alaska', by A. C. Gill, just published as the Geological Survey's Bulletin 712-D. The deposits described occur at two places, both in the southern part of the Kenai peninsula. One is on tidewater at Port Chatham and the other about 16 miles inland. Large bodies of ore have been found at both places.

The First Miners and the First Civilization

By GRANT H. SMITH

The ancient and honorable vocation of mining is of such remote antiquity that Tubal Cain, "the instructor of every artificer in brass and iron", may be considered quite modern. Iron came into use not earlier than 2000 B.C., which sets a definite chronological limit upon the blacksmithing activities of the famous early descendant of Adam. The Bronze (copper) Age had its beginning in Egypt about 4000 B.C.; but underground mining for flints began in Western Europe 10,000 years ago. For the making of their fine stone implements and other artifacts, the New Stone Age men were not satisfied with the flints that could be picked up on the ground, as their ancestors had been for 50,000 years, so they began to dig for them. They were the first miners. Eighty of their worn deer-horn picks were found recently in the tunnels of the flint mines at Brandon, England. Even the skeleton of one of these early miners has been found in an old flint mine in Belgium, lying beneath a fall of rock from the roof of his tunnel, with a deer-horn pick still clasped in his hands.

The first metal-mining was done by ancient Egyptians in the copper mines of the Sinai peninsula nearly 6000 years ago. The stopes, looking very modern, are still open, and on the walls are the inscriptions of the early miners. We have their copper chisels and moils—shaped like our tools of today—their clay canteens and heavy stone picks. Already those wonderful people had discovered the art of smelting ore. Only in recent years have metallurgists succeeded in devising processes more successful and efficient. The copper-bearing ores that they dug and smelted were chiefly turquoise containing about 33% of copper oxide; a hydro-silicate of copper; and granitic rocks bearing a small percentage of carbonate and hydro-silicate. The highest grade of ore was a hydro-silicate.

In the Pyramid Age, 3000-2500 B.C., the Egyptians invented a tubular drill, which worked on the same principle as our modern diamond-drill and produced a perfect core of hard rock. Presumably the drill was of copper, and was fed on its cutting-edge with something like emery-powder, just as those extraordinary craftsmen fed the long copper saws with which they sawed blocks of stone for their buildings and monuments. The shaft of the drill was revolved by hand by means of a crank at the top, the turning-motion being assisted by two heavy stone 'governors' swinging just below the handle.

The story of Egyptian civilization has been told a thousand times, yet the wonder of it grows with increasing knowledge. We of today owe much to Greece and to Rome—our civilization would scarcely exist but for them—but Egypt was thousands of years old and decadent

before the Greeks had emerged from the condition of simple barbarism.

Egypt was the mother of civilization. From her all of the ancient peoples learned nearly all they knew. She gave to the world agriculture, irrigation, the domestic animals, fruits and vegetables, the alphabet, paper, ink, architecture, sculpture, painting, glass-making, goldsmithing, weaving, other arts and crafts of various kinds, the mining and smelting of ores, metallic tools and weapons, the calendar, the first knowledge of the stars, the art of building sea-going ships, tools, many useful mechanical inventions, the first moral precepts, the belief in immortality, and an elaborate and efficient administrative system. All of these things she had devised and largely perfected over three thousand years B.C.

The scientific and mechanical accomplishments of the 19th century, wonderful as they are, pale beside the achievements of the early Egyptians, since they *created* mechanics and the sciences. They had no teachers; civilization arose with them.

In one domain only did the Egyptians fail to excel—that of the intellect; they produced no great philosophers and no literature of value. Their ancient code of laws has not survived.

It is almost incredible that such progress should have been made—from barbarism to a high state of civilization—in the thousand years before the 30th century B.C., yet such is the conclusion of the authorities.

Egypt traded with the then known world and carried her knowledge and progress to many peoples. Some of her trading ships ranged the Mediterranean; others traded along the coasts of the Red Sea, carrying Egyptian products and bringing back spices, gums, ivory, gold, etc. About 2000 B.C. a great canal was dug from the Nile to the Red Sea, enabling ships to pass from the Mediterranean to the Indian Ocean.

Originally, in the early ice ages, when the Sahara was a fertile plain, the present valley of the Nile was a rough fault-plane in limestone, nearly five hundred miles long, through which an enormous river rushed to the sea. Gradually the river declined in volume and the gorge silted-up; morasses and lakes succeeded, alive with great game and waterfowl, which were hunted by the Old Stone Age savages. Gradually the marshes became alluvial plains, yearly enriched by the overflowing Nile. The hunters became herdsmen, domesticating the wild animals; then learned to plant crops, then to irrigate. Irrigation demanded a settled community-life, so villages sprang up; population increased, little city-kingsdoms were formed, various arts and crafts had their beginnings. With increasing community life and growing

wealth, progress in all directions was rapid. One man made himself king of all of the city-kingdoms of Lower Egypt, another became ruler of Upper Egypt. Then Menes, a great warrior and administrator, made himself king of all Egypt, and the line of Pharaohs began. This was 3400 years before Christ, according to Breasted and his school, although Petrie fixes the date at 2000 years earlier. The shorter chronology is now generally accepted.

During the Pyramid Age, 3000-2500 B.C., Egyptian civilization rose to its greatest height, from a material point of view. Professor Breasted says: "No century in the history of men, except the 19th century of our era, has witnessed as rapid an extension of man's control of material forces as the 30th Century B.C."

In all great civilizations, periods of tremendous energy and accomplishment have been followed by reaction and decline. Wealth and soft living appear to be fatal to mankind. Egypt's first period of depression set in before 2500 B.C. and lasted about five hundred years; to be followed by a notable rejuvenation in the Feudal Period, or Middle Kingdom, about 2000 B.C. Following another decline, came the invasion of the Sxythians, the Shepherd Kings, who were expelled after two centuries when Egypt found herself again about 1500 B.C. Then, for the first time, Egypt became a great military power, in what is called the Empire Period; her conquests extended as far as the Euphrates. The great city of Thebes, on the upper Nile, which even in its ruins is one of the wonders of the world, is a monument to the splendor and power of this period.

The Empire lasted a few hundred years and slowly crumbled from internal decay. Egypt's sun, which had illumined the then known world for thousands of years, was hastening to its setting. In the 7th century B.C. the wolfish Assyrians ravaged the valley of the Nile, followed, after a few centuries, by the conquering Persians. Then came the Greeks under Alexander the Great, and, finally, the Romans. Cleopatra was the last of the mighty line of the Pharaohs.

What of the future of present-day civilization?

Volatilization in Assaying

By FREDERIC P. DEWEY

*It is common to blame irregular assay results upon volatilization and much has been written upon the subject, but there is no real evidence that, in a properly conducted assay, the loss of either gold or silver by volatilization is sufficient to affect appreciably the result, even when arsenic or antimony may be present. Bulk assays of flue-dust from assay muffles have been published, but the data given are totally insufficient to even approximate the volatilization from a single assay; and such figures as we have indicate the volatilization to be extremely small. Diligent search in the literature and

wide inquiry among assayers and instructors have failed to produce a single case where the litharge volatilized in making an assay has been collected and assayed for gold and silver. Having attempted to do this, with most indifferent success, I am not surprised that this has not been done.

While various textbooks give volatilization as a cause of loss in cupellation, it may safely be said that in the rare cases where this volatilization is sufficient to affect appreciably the result it is due to excessive temperature. Percy says "The loss of silver by volatilization during cupellation is very slight (unless the temperature has been much too high), and may be disregarded." This statement is repeated by the Beringers and Smith, who include gold with silver. Mitchell says the litharge fume rarely contains over one ten-thousandth of silver. Campredon says that at a proper temperature no silver is lost by volatilization.

Primarily, excessive temperature may be due to too high general temperature in the muffle; but it may often be due to temperature localized within the bead by oxidation of the metals and this may be influenced by other causes than the general temperature. I have shown an extreme case of local temperature, resulting in the burning of zinc with its characteristic flame and variations in bead temperatures with uniform pyrometer readings. Volatilization from a bath of mixed metals is not the simple question of vapor pressures of the contained metals. Based entirely upon vapor pressures, Richards, in speaking of the distillation of zinc from Parkes crust, says "Successively larger amounts of lead, silver, and gold come over the higher the temperature," but I have shown that more silver goes with the zinc in the early stages of the operation than later.

The possible volatilization of the precious metals in cupeling is a most complex proposition. It may be due to the vapor pressure of the individual metals, the vapor pressure of alloys or possible metallic compounds, of compounds of metals with metalloids or with non-metals, particularly oxygen.

Many statements regarding volatilization in assaying are based upon data obtained under conditions entirely different from cupeling and much that has been written fails to distinguish between volatilization and dusting, which is purely mechanical. In practical operations, losses are often ascribed to volatilization that are largely, if not entirely, due to dusting and other mechanical causes.

Various persons have reported the finding of gold and silver in the fumes condensed in the flues or muffles, but these generally show only minute quantities of the precious metals and all lack quantitative significance.

DURING 1919, 315 inspections were made by the Industrial Accident Commission of operations involving the safety of approximately 16,000 men employed in California's operating mines, mills, smelters, gold dredges, quarries, and construction tunnels, which work comprised underground and open-pit workings and reduction plants.

*Abstract of paper presented at the New York meeting of the A. I. M. E.

Discussion of Flotation at the Idaho School of Mines

The 'Flotation Conference' held at the School of Mines of the University of Idaho at Moscow, March 1 to 6, was attended by more than thirty visitors, and these, together with the faculty of the School of Mines and the research staff of the Federal and State Mining Bureaus, made a group small enough for good discussion and large enough to give life to the proceedings. A feature of the meeting was the liveliness of discussion. While every statement made by a speaker was scrutinized most sharply and questioned wherever doubt or ambiguity was apparent, the utmost good humor prevailed throughout. A number of phases of flotation practice were discussed in detail and certain general principles were agreed upon by the majority; not, however, without some dissenting opinion.

The main conclusions of the discussion on grinding, led by W. L. Peniek of the Hardinge Co., may be summarized as follows:

(1) Ball-mills have displaced practically every other form of crushing-machine for final grinding, although it is possible that the disparity between them and chilean mills, stamp-mills, and other machines would probably not be so great if the latter, instead of depending on screens for sizing, could be run on the overflow principle and in closed circuit with a classifier, as is done in standard ball-mill practice. Cylindrical ball-mills, however, require less space than any other form of crushing device.

(2) Stage reduction is still pre-eminent and likely to remain so as long as present devices are in use. Attempts to reduce 3-in. material to 100-mesh product in one operation are inexpedient and wasteful. One-inch feed for fairly soft ore grading to 1-in. for the hardest ore will yield the best results.

(3) Extremes of practice in ball-mill grinding are represented by the Inspiration plant where 3-in. material is reduced to pass 48-mesh at one operation, and by the mill of the Canada Copper Co., where crushers and rolls reduce the ore to 10-mesh, after which it is ground to 100-mesh by two-stage ball-mill reduction.

(4) If some means could be found of eliminating the already sufficiently fine material from the return feed more effectively than is now done, much greater capacities could be obtained. This points to better classification in the ball-mill circuit.

(5) The peripheral speed of ball-mills should vary inversely as the fineness of grinding: 375 to 400 ft. per minute for 48-mesh product and 550 to 625 ft. per minute for coarse grinding, say, 8-mesh.

(6) Trunion-overflow mills are, in general, superior to mills with grated discharge in capacity and character of product.

C. A. Wright of the U. S. Bureau of Mines discussed flotation testing. In addition to describing standard methods, he brought out the following points:

(1) Flotation testing should be preceded by careful

mineralogic examination of ores and in many cases by segregation of the various minerals in the ore and the assay and analysis of each segregate to determine the disposition of the various metal ingredients.

(2) Intelligent use of the microscope in examination of heading, concentrate, tailing, and intermediate products; also examination by the microscope of polished sections to show mineral association are vitally important. The application of this work to certain zinc-lead ores of the Coeur d'Alene has shown that in 200 mesh particles magnified to 1-in. diam. there are particles of galena the apparent size of wheat grains imbedded in solid sphalerite and at times similar areas of sphalerite surrounded by galena. It is evident of course that nothing short of molecular dissociation can separate zinc and lead in such ores.

(3) Wet crushing preliminary to testing for flotation has generally yielded results from 5 to 10% higher than is yielded by the same treatment applied to ore samples crushed dry.

(4) Satisfactory differential flotation of zinc-lead ores of the Coeur d'Alene can be made, provided the ores are not of the character discussed in paragraph 2. Such separations show recoveries of 80%, with lead products assaying 60% lead and 6 to 8% zinc; and zinc products containing 40 to 45% zinc and 5 to 6% lead. Mixtures of No. 2 or No. 4 Barrett oils with coal-tar cresosote in sodium silicate or carbonate solution generally give good results.

(5) Results secured under laboratory conditions may not be duplicated under mill conditions owing to difference in character of feed, elimination of certain substances, or inclusion of certain other substances during the milling process. The use of mill-water may give different results to those obtained by employing clean hydrant water.

R. S. Handy, superintendent of the Bunker Hill mills, though not presenting a formal paper, made notable contributions to the conference by his timely queries and comments. One of Mr. Handy's theories is that if we can eliminate the colloidal material from a pulp and then size the non-colloidal portion carefully, much better results can be secured either by gravity concentration or flotation. Indeed, Mr. Handy holds that once the colloidal material is out of the pulp it makes little difference which of the two methods of concentration is used. R. B. Elder showed in the laboratories the possibility of arranging various oils in the order of their interfacial tension with water. The first oil in the series was dropped on water and spread into a film, this film being in turn displaced by a film made from a drop of an oil of lower interfacial tension, and so on down the series. It is evident that if the same principle could be applied to the attachment of oil films to minerals, and if a definite series of 'affinities' could be worked out, we would have

made some further progress along the path of differential flotation.

An effort was made to enumerate important phases of flotation concerning which information is lacking. The following were agreed upon as needing further investigation:

(1) Maximum and minimum size of particles recoverable by flotation.

(2) Relation between size of bubbles and size of particles.

(3) Relative floatability of the members of the series galena, chalcopyrite, sphalerite, pyrite, and pyrrhotite.

(4) Influence of depth of column on effectiveness of the bubbles in collecting mineral.

(5) Affinity or adhesion between various minerals and different oils.

(6) Is classification desirable preliminary to flotation?

The flotation of coal was the subject of a paper by O. C. Ralston, recently appointed superintendent of the U. S. Bureau of Mines at Seattle. This paper, read by A. M. Piper, pointed out the applicability of flotation to the beneficiation of low-grade slack or culm-piles and to the recovery of coal from domestic ashes, which could be collected and brought to a central plant for treatment and recovery of the 20% of coal which it is estimated they usually contain. L. A. Grant in the absence of W. L. Ziegler, who was detained by a professional engagement, discussed the design of the Loon Lake Copper Co.'s plant in Washington, 50 miles north of Spokane. This plant, designed and built by Ziegler, although quite small in size, has attracted considerable attention owing to its compactness and simplicity. The ore consists of clean chalcopyrite in clean quartz, an ideal ore for separation. Remarkable results are reported with more than 95% recovery having been made. The equipment of the plant is ridiculously simple, consisting of a 10 by 15-in. Blake crusher followed by a 24-in. Symons disc-crusher, feeding two 4 by 4-ft. cylindrical ball-mills crushing to 65-mesh. The entire pulp then goes to a Ziegler flotation-machine that produces clean concentrate in one operation. No. 5 distilled pine-oil is used.

J. Benjamin Parker, metallurgist for the Interstate-Callahan company, in an informal address, stated that shortly before returning to the Coeur d'Alene he had had considerable success with the use of SO_2 gas in selective flotation on a small scale. The gas immediately renders the blende non-floatable, thus permitting the floating of galena in presence of sphalerite. There is some question whether the SO_2 is best added intermittently in thickeners or other storage tanks, or whether it can be used to better advantage in the flotation-cell itself. An interesting point was made by Mr. Parker on the effect in the Interstate-Callahan mill of burning sulphur in the vicinity of the zinc-flotation machine, the zinc froth being 'killed' entirely for a considerable period, to the great mystification of the mill operators.

M. H. Sullivan, metallurgist of the Bunker Hill smelter, discussed the difficulties introduced in lead-smelting practice by the necessity for handling flotation

concentrate. The main objections from the smelter's point of view are as follows:

(1) Difficulty in unloading from cars when received at the smelter, much of the material being sticky and clinging to shovels, the wheelbarrows, bin walls, and chute gates, and being almost impossible to sample. In certain cases men practically refuse to handle some of the material sent in.

(2) Mechanical handling of the stuff on belt-conveyors, belt-feeders, spouts, and the like is in many cases impossible.

(3) Extreme difficulty in getting a uniformly roasted product from the Dwight & Lloyd machines. Lumps and unroasted masses are produced, thus leading to excessive matte-production and development of furnace-accretions, unless re-crushed and re-roasted.

(4) Extra fuel consumption required to dry the material.

The remedies for these conditions would appear to lie in more careful elimination of moisture at the mills either by American filters, which were reported to be doing good work at the Hayes mill below Kellogg, or in Oliver filters, which many mills are using. The Lowden dryer is also being used at the Hayes mill with fair success. A new type of dryer devised by Elmer Brain, who is operating a tailing mill at Kellogg, was reported to be giving good results. The obvious disadvantage of paying freight on water makes evident the need of drying. From 5 to 7% was stated to be the desirable moisture content in flotation concentrate to be sent to roasters of the D. & L. type. The mixing of flotation and gravity concentrate would appear to be desirable. Unless flotation operators show a little more consideration for the smelters a penalty will have to be placed on flotation concentrate carrying excessive moisture.

Among those present were L. K. Armstrong, W. H. Linney, J. C. Ralston, and J. V. Richards of Spokane; M. H. Sullivan, superintendent of the Bunker Hill smelter, and R. S. Handy, superintendent of the Bunker Hill mills; J. B. Parker of the Interstate-Callahan and Frank H. Skeels of Wallace; W. E. Wichman, University of Washington, Seattle; Professor C. G. Warfel, Washington State College, Pullman; E. R. Abernethy, Fort Steele, B. C.; J. J. Stanford, Rocky Bar, Idaho; C. D. Dolman, Chewelah, Washington. As indicating the nature of the interchange of ideas it may be said that small operators were delighted at the advice and assistance received, and one man who stopped a job of mill-construction to attend the conference said, "what I've got here has been worth five thousand dollars to me".

Tin shipped from Potgietersrust, South Africa, in 1919 shows an increase of 183 tons as compared with the previous year. The value of the tin produced in 1918 reached the record figure of £440,995, an increase of £94,979 compared with the previous year. Tin was exported to the Argentine to the value of £20,700 and to Portuguese East Africa to the value of £9345. Small consignments were also exported to South-West Africa and Japan.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ALASKA

TRANSPORTATION BY HYDROPLANE.

HYDER.—H. J. Bush, at one time owner of what now is the Premier mine, recently returned from England. He states that the Selukwe Gold Mining & Finance Co. has taken a third interest in three properties controlled by C. B. and H. J. Bush and associates. These properties now are administered by the Bush Mines, the B. C. Silver Mines, and the Salmon-Bear River Mining Co. It is understood that a single company to be known as the British Canadian Silver Corporation will be formed to take over the three first mentioned and that the Selukwe Gold Mining & Finance Co., which will subscribe the working capital, will take shares in the new company. These three holdings are said to embrace about 50 claims from which some high-grade ore has been taken but which have yet to be developed.

Roy Price, formerly in the employ of the Granby Consolidated Mining & Smelting Co., is behind a project to use hydroplanes from Hyder or Stewart for the transport of light supplies to the properties now under development in the Salmon River district. There are no mountains of extremely high altitude to cross along the route and in an air-line the distance is less than 20 miles. On return trips it would be possible, if the hydroplanes are a success, to bring to tidewater such high-grade ore as might be available for shipment. Ernest O. Hall, a Canadian aviator with overseas experience, is one of those interested and with him is associated E. Hubbard, of Seattle. The former states that a Seattle firm has contracted to deliver by April 15 one specially designed flying-boat and two more of the same model by May 15 next, and if these are satisfactory three more will be built for delivery on or about June 15. Each plane will have a carrying capacity of approximately 40 cubic feet.

The strike which has been interfering with operations at the Premier mine is reported to be settled, an advance of 50c. per day being granted the workmen, together with other concessions, among them the undertaking to employ a competent cook.

In the Marmot River section of the Portland Canal division there has been little mining during the past several years outside of assessment work, but the intense activity along Salmon river and high silver prices are stimulating activity. The Montana group of claims, situated in this locality, has been acquired by the Stirling Mining Co., which concern also has taken over the Grand View group of four claims. The ores of both carry silver

and lead. The Kay-Bee-Bird group, also of Marmot river, is reported to be bonded to a Vancouver syndicate.

ARIZONA

PROMISING DEVELOPMENT AT KINGMAN.

DUNCAN.—W. O. North, former assistant manager for the United Eastern Mining Co., has purchased the dump of the old Rand mine at Searchlight. The ore will be hauled to the Duncan mill where it is to be cyanided.

KINGMAN.—The drift from the cross-cut that recently opened ore on the 450-ft. level of the Telluride mine at Oatman has opened rich gold ore. Ore was found on the 330-ft. level of sufficient grade to warrant the present deeper development. This find has caused a decided advance in the Oatman gold stocks listed on the Los Angeles exchange. The Tuckahoe mine management at Chloride has finished cutting the station at the 550-ft. level and has started drifting on the vein toward the old shaft. Ore so far developed in this work is better than that penetrated on the 350-ft. level. At a recent meeting of the stockholders at Oatman of the Oatman Consolidated Mines Co. the capitalization of the company has been increased from \$150,000 to \$1,500,000. More money is to be raised to continue the development work that is now planned.

In re-opening the Golden Star mine at Mineral Park a streak of ore was broken into on the 150-ft. level that ran 400 oz. silver and \$9 gold. A winze is to be sunk. It is announced that the Kingman Consolidated Mines Co. has been organized to take over the Arizona Buttes Mines Co. The stock in the latter is to be exchanged for stock in the former company share for share. It is reported that the Leland Mitchell group of mines is to be equipped with new machinery to develop the ground recently opened by the new 700-ft. shaft. The Gold Bug property in the Minnesota district is to be sold at auction as a result of the action of Ellen J. Crosby of Colorado Springs who has obtained an order of dissolution against the company for the purpose of settling the indebtedness. It is reported that the consolidation of the Hackberry Consolidated Mines Co. and the Senate Silver is practically certain within the next thirty days through the action of the principal stockholders of the Hackberry. Development on the 80-ft. level of the Home Pastime mine at Mineral Park has opened a body of ore. Preparations for the first earload shipment are being made.

MAYER.—The Canon Mining & Development Co., four miles north of the Kay mine, is now having its Black

Canyon claims diamond-drilled. The first hole penetrated schist at 135 ft. and showed some copper. A second hole is now being drilled. The old Tip Top mine is being unwatered with a view to operation by the Arizona Tip Top Co. under the management of J. F. Coupal. A wagon road is being constructed to the mine to haul in machinery and other equipment.

MUMT.—It is reported that the Gibson Consolidated Copper Co. will renew operations in about 60 days under the management of H. M. Towle Sr., the former manager. The Ray Boston Copper Co. has resumed operations on the Kelvin-Sultana property near Kelvin. It is said that exploration by diamond-drilling is to be carried out. It is reported that the Arizona Globe Copper Co., which is now developing the Cole-Goodwin property, has taken over the Independence group owned by the Independence Development Co. Some ore has been shipped to the Old Dominion smelter and the property has been leased intermittently.

PATAGONIA.—It is reported that a new three-foot vein of silver-lead ore has been opened in the Flux mine. Development is progressing rapidly.

COLORADO

REVIVAL OF MINING IN THE OURAY DISTRICT.

OURAY.—From all indications there is to be a revival of mining in this section. New leases are being drawn up from time to time, and all the operating companies are planning increased development and production. The favorable weather of the past month has been of great advantage and many operators are making an earlier start than they had anticipated. Eleven men are at work at the Portland mine. A body of ore has been opened up in the main drift. The vein is two feet wide, and extends for a distance of 1000 ft. The average value of the ore is reported to be \$25. The Paymaster mine has been leased to the Paymaster Mines Co., with the main offices at Denver. The officers of the new company are J. B. Fowler, J. E. Kelley, and John W. Cox. The Mountain Top Mining Co. has purchased the Agnes claim, owned by Thomas Mowatt, for the reported sum of \$15,000. This claim, which has been worked for the past sixteen years by the owner on a small scale, is situated in the centre of the Mountain Top group, and a vein of high-grade ore is said to pass through it.

The Eurades Mining Co., formed by Chicago capitalists, is to re-open the Des Ouray and the Benach. Development will be necessary in order to put the properties in shipping condition, and a large amount of machinery and equipment has already been ordered. The Des Ouray cross-cut will be the main operation. The Benach and other veins will also be explored. The Iron-ton mill is to operate during the coming season on custom ore.

RICO.—A statement issued by the Rico-Wellington Mining Co. confirms reports that there has been a discovery of a large body of good ore. East of the old Logan workings a vein of lead carbonate averaging six feet in thickness was opened. Under the new ruling of

the War Minerals Relief Board, the Rico-Wellington company will lose approximately \$30,000, the amount of money expended in developing iron pyrite. The claim was rejected on the ground that the company was not drafted. Efforts are now under way to make a market for the material to compete with the Spanish output.

PARADOX VALLEY.—The Uranium Chemical Co. has taken over the holdings of the National Radium Products Co. The Colorado Vanadium Co. is leasing a number of claims to small operators, who are getting out a heavy tonnage of ore in the aggregate.

OPHIR.—The San Bernardo mill buildings and tramway will be completed in May. The Ruuttilla-Brown Leasing company is shipping from the Carbonero, and a force of men is at work on the Deadwood tunnel, driving toward the Favorite vein. J. M. Belisle & Co. is mining from the lower level of the New Dominion a lead-zinc product that is being shipped to the Utah smelters.

TELLURIDE.—The railroads have been blocked for several days owing to the heavy slides, and a large amount of ore has accumulated in the bins of the Tomboy and Smuggler. Illness among the miners curtailed production for the first part of the month. The Smuggler Union Mining Co. has completed operation of the Caruthers mill, of the Smuggler company, and now has plenty of water-power so that the mill can be worked at full capacity. Shipments of concentrate are being made.

SILVERTON.—The body of ore in the 'Lost Stope' of the Gold King is reported to extend down to the seventh level, a distance of 400 ft. A slide took out the power-line to the Gold King, stopping operations for a few days. The grade of concentrate is steadily improving. Todroschi & Co., sub-lessees of J. B. Giono, on the Silver Lake mines, after a long period of development are now ready to ship. The Highland Mary Leasing Co. is getting out an average of a car per week of high-grade silver ore. The Sunnyside M. & M. Co. has 58 cars of lead concentrate ready for hauling when railroad facilities are available. The Southwestern Mining Co. is getting out several cars of concentrate each week. For a short time production will be curtailed, owing to the destruction of a tower on the Iowa-Tiger tram by a snowslide. The same slide also damaged the mill to a small extent. The Gold Centre group at Animas Forks is to be developed as soon as snow will permit. The operators are wealthy oil men who will use their own capital in the development work.

MICHIGAN

SENECA SHAFT BEING CONCRETED.

Houghton.—Seneca has made a third shipment of copper ore to the Baltic stamp-mill. It ran 55 lb. of copper to the ton. This is all the lode 'rock' that likely will be sent to the mill from the Seneca property for the next few months as it cleans up everything in sight. The last shipment was smaller than the first two, consisting of but five cars which were loaded from the stockpile. No lateral development now is being done. The station at the 4th level was cut this week as well as a transfer chute for

future use. Ten feet of cross-cutting to the lode has been done on the 4th level but this work is temporarily suspended while energy is directed to the job of concreting the shaft. A total of 275 ft. of this work is yet to be done. The steel timbering is all in and the skip road laid. The forms for the concrete will be in place in a couple of days. Work of this nature cannot be hurried. The present depth of the shaft is 2145 ft. and no sinking can be done until the concrete in the shaft is set.

The unwatering of the Gratiot No. 2 shaft has been finished and the shaft opened for a depth of 1520 ft. This

shaft was re-opened a month ago. The decision not to continue this work was reached, not because of any unfavorable physical developments in so short a time, but rather on account of the difficulty in securing enough men. The shaft was opened at the 25th level. Such new openings as were made in the brief period of operation showed a general run of 'rock' quite up to the average for the northern end of the Mohawk territory. It is the belief that this No. 1 work may be resumed sometime this year, probably about July. Sinking continues at No. 4 and at No. 6 shafts and the output for the whole mine is

SULPHIDE ACID PLANT OF THE CALUMET & ARIZONA COMPANY AT DOUGLAS

is the only shaft that will be operated at the Gratiot this year, according to the present plans. It will take a month or more to get it in shape to resume sinking or to start lateral exploration work. This is the more southerly shaft and is nearer the Seneca line. A survey now is being made of the underground conditions before sinking starts. A good deal of repair work will have to be done to the skip-way and to the roof of the shaft in numerous places. The shaft is in trap for a distance of 400 ft. toward the bottom level. The diamond-drill, after cutting three holes in the Calumet conglomerate, is back in No. 1 hole again and is cutting to greater depth with the expectation of opening several other formations, particularly the Oseola amygdaloid. The drill is operating directly west of the Seneca shaft at right angles to the dip.

Mohawk has suspended operations at No. 1 shaft. This

averaging 1800 tons per day. Another battery-locomotive has been added to the underground equipment at No. 6 shaft and it is doing satisfactory work. This is the second of the battery type to be put to work in this shaft. The Mohawk has been using trolley locomotives for tramping exclusively. Mohawk is making some improvement at the stamp-mills. New re-grinding machines have been added with the result that the losses in the tailing have been reduced from 4.8 lb. to 3.6 lb. per ton. Further re-grinding experiments have led to the conclusion that more work may be done in that direction and at least one and perhaps two more re-grinders will be added with the hope of saving still more copper.

Operations in the cross-cut in the Mayflower-Old Colony property continue without change. The cross-cut now is in 50 ft. There is practically nothing of interest to report either from a viewpoint of geologic development

or mineral indications. The management is continuing its work on the policy of opening this broken area as conservatively as possible and without any unnecessary outlay to the shareholders. At the present time there is nothing in the character of the ground that is encouraging; yet it would be a serious error to discontinue this cross-cut without making the examination thorough. This work is at a depth of 1710 ft. from the surface and started from a point in the drift 100 ft. from the shaft.

NEVADA

SIMON SILVER-LEAD MINE.

MINE.—The Simon Silver-Lead Mines Co.'s property near here is a young mine, the lowest working level being approximately 400 ft. from the collar of the shaft. Yet at that shallow depth there has been exposed by drifts and cross-cuts more than 500,000 tons of ore, and the development of a really big mine is probable. Some fifty years ago when the district was remote from the railroads the property was discovered by a prospector named Story, who later abandoned it. It was re-located by another prospector named Williams. Probably Senator Bell, a pioneer resident of Nevada, who leased the ground from the owner, shipped the first ore, a lead-silver carbonate which he mined after sinking a 60-ft. shaft. This shaft is known at present as the upper shaft and is about 450 ft. from the main working shaft.

In 1916, P. A. Simon bought an interest in the property and later acquired the present holdings of the company. These consist of eight mining claims of approximately 150 acres over an area almost a mile long and from 1200 to 1500 ft. wide. The mine has been opened on six levels. These have been driven from the main working-shaft, which has attained a depth of 467 ft. Work on the tunnel-level, driven through volcanic breccia, indicates an ore deposit approximately 365 ft. long up to the east fault and the outcrop beyond this fault is known to carry ore for an additional 200 ft. This work is the earliest development work done on the property and there is still left in these workings a large amount of carbonate ore of shipping grade.

The second level was started at a depth of 80 ft. There are about 180 ft. of workings on this level. Ore shows near the shaft and in two raises, but practically all the remainder of the work has been done in oxidized vein matter. At a depth of 130 ft. the third level was driven. It has more than 500 ft. of workings, a large portion of which is in a leached material containing carbonate ore of shipping grade. The fourth level was started at a depth of 230 ft. and on this level there has been developed for a length of 120 ft. what is termed the south orebody, with an average width of about 35 ft. One shoot in this orebody is 16 ft. wide and 20 ft. long.

Two distinct orebodies have been opened on the fifth level driven from the 291-ft. point. These orebodies are separated by a mass of quartz-porphphy 25 ft. wide. The south orebody has been developed by driving three cross-cuts between 80 and 100 ft. apart and also by a drift along the hanging wall. It has an average width of 20 ft.

and the workings indicate that it extends for a distance of about 225 ft., being limited by the east and west faults. The sixth level, driven from a point 391 ft. below the collar of the shaft, shows the same orebodies that have been opened on the fifth level. The workings on this level aggregate more than 1100 ft., with more than 230 ft. of main cross-cut. Upon the resumption of sinking operations recently, the shaft-men uncovered small stringers of ore which widened to three feet.

The orebodies are large and occur as replacements in the crushed limestone adjacent to the quartz-porphphy contact and are of the type that has been developed vertically and laterally in other mining districts such as the Tintic district of Utah and at Eureka, Nevada. Operations are supervised by Burch, Hershey & White, of San Francisco, this firm at present being engaged in the design of a mill to treat the ore.

MONTEZUMA.—The Montezuma Silver Mines Co. has opened 30 in. of ore assaying from 150 to 250 oz. in the bottom of a 260-ft. inclined shaft on the Arizona claim, in the southern part of the district. A 4-in. vein in the shaft assays 100 oz. The shaft has been sunk 10 ft. in ore of this width and grade. Associated with the silver is jamesonite, a sulph-antimonite of lead said to be found in few districts in the United States aside from Montezuma. The vein is 4½ ft. wide, with a shale hanging wall and a limestone foot-wall. The find is thought to have been made a short distance above water-level and the vein is increasing in width and value. An air-compressor has been ordered and, according to the superintendent, the shaft will be continued to 800 ft. The vein strikes east and dips 50° north. The territory from 3 to 12 miles west of Goldfield, which includes Montezuma, may be on the verge of an era of prosperity, but there are no indications that conditions will be better than in other districts where capital has fled before absurd 'boosting' tactics. The Monitor group, 1½ miles from the Montezuma Silver, was to have been taken over by the Harmill Divide company for \$15,000, but it is improbable that the sale will be made, because the Harmill company asks one year in which to complete payments. Three miles west of Goldfield is the Nevada Eagle, said to be one of the best developed silver mines in the State, but the owners are silent regarding recent developments.

GOLDFIELD.—There are well-substantiated reports that a number of companies, including the Atlanta, Merger, Blue Bull, C. O. D., and Commonwealth, are to finance the sinking of a deep shaft in the eastern part of the district. In discussing with a committee of Goldfield men his intention to wreck the Goldfield hotel, George Wingfield stated that he planned to become connected with an Eastern industrial enterprise and that for this reason he desired to lessen his mining and other interests in southern Nevada. It is thought Goldfield men are planning to secure control of his companies here with the object of sinking the deep shaft. A drift is being driven in the vein on the 700-ft. level of the Kewanas and assays of \$7 are being secured. Drifting north from the main Atlanta cross-cut has been stopped because of poor results secured and a drift is being driven south

in the same vein. A cross-cut has been driven 120 ft. into the hanging wall of the vein from the south drift. A drift is being driven north in the vein on the 250 ft. level of the Blue Bull and work is to be started from the bottom of a winze from the 150-ft. level. The west drift on the seventh level of the Florence is 965 ft. long and the south-east drift on the same level is 720 ft. long. Short cross-cuts are to be driven from each to connect with old shafts for air and following this drifting will be started. The west cross-cut is thought to have passed through the Columbia mountain fault, but the management has no intention of stopping this work. Two carloads of ore, one settled for by the smelter at \$93.17 per ton, and the other estimated to be worth \$130 per ton, have been shipped from the Development lease on the Reilly block. Sampling of the 75-ft. cross-cut recently driven through the Mohawk vein in leased territory by the Silver Pick showed the entire cross-cut to be in 'mill ore', according to Mat Murphy, superintendent. It is thought the average is \$15. The vein lies rather flat and it is 40 to 50 ft. wide. A 20-ft. raise has connected with the drift in which the original discovery was made and a drift is being driven on the hanging wall of the vein from the cross-cut. A 20-in. seam in the drift assays \$300 and in sampling the cross-cut a 4-in. vein of \$85 ore was found.

NEW MEXICO

SOCORRO PROPERTY RE-FINANCED.

GRANT COUNTY.—Radium ore has been discovered on the claims of Forster & Grissom in the White Signal mining district. The United States Smelting & Refining Co. has optioned six claims from Forster & Grissom for \$175,000 and will explore the property to determine the extent of bismuth ore also found on the property. Late in 1919 the United States company purchased the property of the Hanover-Bessemer Iron & Copper Co. in the Hanover-Fierro district consisting of concentrator, power-plant, and sundry claims containing iron and copper ores which have been producing more or less continuously for the last 25 years.

SOCORRO COUNTY.—The American Corporation of West Virginia has acquired the mine and mill formerly owned and operated at Mogollon by the Socorro Mining & Milling Co. which went into the hands of receivers late in 1918. Stockholders in the old company will receive two shares of A. C. of W. V. for five shares of S. M. & M. Co. The property consists of the Fanny, Johnson, and Cooney mines, the Fanny being the principal mine with a shaft over 1000 ft. deep. Full equipment is on the ground, including a 240-ton cyanide plant. The new company expects to start active operation within the next 60 days.

OREGON

MERCURY MINING IS PROGRESSING.

GOLD HILL.—David Forcee of Beagle, who has been driving a 200-ft. drift on his mercury mine in the Meadow district, 12 miles north of Gold Hill, has uncovered a large body of cinnabar ore assaying 60% mer-

cury. The new find is a typical shoot found in the mercury bearing lode extending through this district. This vein occurs along a granite sandstone contact, where the granite is in part pegmatitic. Most of the workings of the mine are less than 100 ft. deep. The mineralized zone is from 100 to 200 ft. wide. The ore contains cinnabar, native quicksilver, pyrite, gold, zinc, silver, and a heavy black mineral resembling meta-cinnabarite. Samples taken from several adits assay from \$5 to \$6 per ton in gold, 5 oz. silver, 2.5% zinc, and 1% mercury. The rich cinnabar ore appears all through the mass in the form of seams and kidneys. The seams are from 1 to 20 in. thick and average from 17 to 70% mercury. The Forcee mine is equipped with a 12 pipe mercury furnace

MAP OF SOUTH-WESTERN NEW MEXICO

and has been a producer since 1916. Considerable development work is under way and much rich ore has been uncovered in the War Eagle group, adjoining.

MEDFORD.—John Sullivan, a pioneer mine operator in the Upper Applegate district, has uncovered a rich gold-copper-silver vein eight miles north of the Blue Lodge copper mine and in a practically undeveloped part of the district. The vein is 12 in. wide and assays \$16 gold per ton; it is rich in silver and is the highest-grade copper ore ever discovered in the district. The Upper Applegate district is occupied in large part by old Paleozoic sedimentary rocks with interbedded sills or flows of andesite character. In places these bedded rocks are penetrated by dikes of dark igneous rocks and also by larger irregular masses of tonilite. The sediments in general strike about N. 20° E. and dip at a high angle to the eastward. As elsewhere shown for this entire region they have perhaps been overturned so that the oldest beds now lie above the younger.

UTAH

TAX REPEAL TO BE DISCUSSED.

SALT LAKE CITY.—A meeting of the mining committee of the Commercial Club has been called for March 19, at which time the question of urging the repeal of excess profits taxes will be discussed. The meeting was called by John M. Hayes, chairman. It is believed among mining men that the excess profits tax is responsible for much of the decrease in metal production in the United States. It is said that the dividend paid last December by the Tintie Standard Mining Co. of 23c. per share was done at the expense of more than \$100,000 in excess profits taxes to the Government. The records of the Utah metal mines on file with the State Board of Equalization for last year's operations show that very few made money and that most of them mined only 50% of their normal production. Mining men declare that many of the mines are simply being developed and ore-reserves blocked-out and left standing in the mines awaiting cheaper mining costs and repeal of abnormal taxes.

ALTA.—The Little Cottonwood Transportation Co. will be hauling ore from the mines at Alta as soon as the railroad equipment is overhauled. The operation of the railroad will be of great assistance to the various companies, as some have virtually had to stop mining because all available storage room has been filled. About 2000 sacks of high-grade ore has been mined from the shoot recently opened at the Sells mine in a drift from the 125-ft. level.

PARK CITY.—Gratifying developments are reported from the Naildriver mine. Particularly encouraging has been the work on the 600-ft. level in the drift from the Dunyon cross cut along the north-dipping fissure. In the last 22 ft. of drifting the vein has widened from 2 ft., until, at a point 72 ft. from where the drift left the cross-cut, there is a full face of ore. Inasmuch as ore in this fissure has been opened in a winze 40 ft. above the 600-ft. level, it is anticipated this ore extends from the surface. Shipments for the week ending March 12 totaled 2212 tons as compared with 2310 tons during the previous week. The various mines produced as follows: Judge Mining & Smelting, 661 tons; Judge Mining & Smelting (premium spelter), 25 tons; Ontario, 608 tons; Silver King Coalition, 437 tons; Daly West, 308 tons; Naildriver, 120 tons; and Daly, 53 tons. The Daly Mining Co. has declared its regular dividend, No. 92, of 10c. per share payable April 1 to stockholders of record March 22. The dividend totals \$15,000 and makes the total dividends paid to date \$3,157,000.

EUREKA.—The new loading-platform near the portal of the Iron King tunnel has been completed and the company will be ready to commence shipment of iron ore just as soon as the last rails are laid on the extension of the railroad. The development of this property is said to be progressing in a satisfactory manner. While there has been little news from the Lehi-Tintie during the past few weeks, it is stated that the work in this property is going along in good shape. Fourteen mines in this district shipped 163 cars of ore during the week ending March 12, as compared with 139 during the previous week. The

Chief Consolidated had an output of 35 cars; Tintie Standard, 32; Dragon Consolidated, 27; Eagle & Blue Bell, 13; Colorado Consolidated, 14; Iron Blossom, 11; Grand Central, 7; Centennial Eureka, 6; Victoria, 5; Mammoth, 5; Swansea Consolidated, 3; Gemini, 3; Gold Chain, 1; Empire Mines, 1. One of the interesting projects at the present time is the Bull Hill. This company has put its main shaft down to a depth of 600 ft. and is now drifting on the 600-ft. level, and it seems to be generally conceded that prospects are good. The Tintie Standard Mining Co. has posted a dividend of 10c. per share payable March 29 to stockholders of record March 25. The dividend will aggregate \$117,470, and makes total dividends paid to date \$1,068,452.

BRITISH COLUMBIA

DIVIDEND DECLARED BY CONSOLIDATED M. & S. CO.

VICTORIA.—The case of the British Columbia-Wellington Collieries v. the Pacific Coast Coal Mines, Ltd., which recently was taken to the Supreme Court of Canada, has been decided in favor of the Pacific Coast company. The British Columbia-Wellington Collieries claimed \$85,000 for trespass and the unlawful removal of coal by the defendant, while the latter claimed that permission for the removal of the coal had been granted to them.

NELSON.—L. A. Biggar, a metallurgist from Montreal, has been consulting with the boards of trade and with the individual operators in the Kootenays with the object of ascertaining what support would be given to a private ore-testing and sampling works, were he to start such a plant at Nelson. His idea is to erect a plant for both laboratory and commercial ore-testing. He was given considerable encouragement. The 400-ft. tunnel at the Evening Star mine is approaching the old shaft, and work has been stopped until the shaft is unwatered.

CARBON.—The Lightning Creek Hydraulic Mining Co. is proving its property, near Van Winkle, with a Key-stone drill. J. H. Kilmer and J. Burnett are sinking a shaft to connect with the old tunnel at the Antler Creek Gold Mines property. They will be in a position to haul gravel by the spring. A number of placer locations have been staked, and considerable activity is expected in the district next summer.

ALICE ARM.—David J. Hancock, the well known operator in this district, is authority for the statement that Sir John Carson, president and managing-director of the Crown Reserve Mining Co., of Cobalt, will visit the district with two engineers. They will examine a number of properties.

A. J. T. Taylor, president of the Taylor Mining Co., accompanied by C. M. Rolston, vice-president, and G. Nutter, representing the Minerals Separation Co., is visiting the Alice Arm district. The party proposes making a survey of the scene of this year's operations in connection with the Dolly Varden mine. Plans no doubt will be considered with reference to the additions to mine plant and railroad equipment.

PRINCETON.—The Nickel Plate mine, at Hedley, which has been closed on account of labor trouble and the gen-

eral depression in the gold-mining industry, has been reopened with 170 men on the payroll. The rise in the price of arsenic is a considerable advantage to this property. Last year the Tacoma smelter paid \$17,000 for the arsenic received in the company's concentrate.

TRAIL.—Ore receipts at the Trail smelter of the Consolidated Mining & Smelting Co. for the first week in March were 3538 tons, bringing the total for the year up to 57,384 tons. Shipments from the Rossland mines of the Consolidated company ceased with the opening of March, which was to be expected in view of the announcement that for a time work on these properties was to be confined to development. A dividend of \$261,936 has been declared by the Consolidated Mining & Smelting Co., payments to be made on April 1 to shareholders of record on March 10. The pending payment will increase the total dividend disbursements to \$6,567,211. Simultaneously with the dividend announcement comes the statement that the company has broken ground at Trail for a large new concentrator, and is considering the construction of another at Kimberley for the treatment of the ores of the Sullivan mines. The Trail mill will dress the ore of the Rossland mines. If the report regarding the latter is authentic it means that the management has decided definitely in favor of Trail as against Rossland as a site for the new plant.

COWICHAN.—The 'Hill 60' manganese mine of the Cowichan district is being equipped for uninterrupted production. An aerial tramway, designed by A. W. Davis, is being erected. It is a two-bucket balance tram, having a capacity of 30 tons in 8 hours, and is costing about \$10,000. Six towers carry the cable to the mountain-face, whence the wire runs for a span of 3600 ft. to the Esquimalt & Nanaimo railway, the total length of the cable being 4750 ft. Bunkers are being constructed both at the workings and at the railway. Since last spring about 500 tons of manganese ore has been shipped to the Billrowe Alloys Co. of Tacoma. The open-cut now discloses a 25-ft. face of 50% manganese ore, although the orebody has not been extensively explored.

ONTARIO

CANADIAN MINING INSTITUTE MEETS.

TORONTO.—The 22nd annual convention of the Canadian Mining Institute, held at the King Edward hotel, March 8 to 10, proved one of the most successful and interesting gatherings in the history of the Institute. The opening address was given by Harry Mills, Ontario Minister of Lands, Forests, and Mines, who tendered a hearty welcome to the convention on behalf of the Provincial government, and outlined the policy which would be followed for the encouragement of prospectors, including a reduction of the license fee to \$5 and the providing of free assays for ores.

D. H. McDougall, president of the Institute, in his annual address referred to the frequent statement that the natural resources of Canada were 'inexhaustible' and 'unlimited' as misleading. They were not by any means as extensive as those of the United States being relatively

limited as regards the three basic requirements, namely, coal, iron, and wood. The coal deposits are largely under the bed of the ocean and their utilization is dependent on the progress of submarine mining. There were large occurrences of iron ore but mainly low in grade. The full use of Canadian resources, he pointed out, was dependent on the advance of applied science, but this was hampered by want of recognition and the inadequate salaries paid to technical experts. The Institute should urge the Government to increase the usefulness of the Geological Survey by providing a larger appropriation.

James McEvoy presented the report of a committee

ALTA, UTAH

appointed to consider the status of the engineer, reviewing proposed legislation on the subject. The opinion was expressed that legislation, which might be suitable to other branches of the profession, would not be acceptable to mining engineers. Restrictions which would prevent investors employing men in whose judgment they had confidence to make investigations would not be desirable and would tend to discourage mining investments.

M. E. Wilson described the molybdenite occurrences of the Ottawa valley, where, though the demand had decreased since the War, some companies were still carrying on operations. The future of the industry depended altogether upon the demand. The principal feature of the evening session was an illustrated address by J. C. Nicholls, general superintendent of the International

Nickel Co. of Canada, describing operations at the Crompton mine at Sudbury.

At the morning session of the second day F. W. Gray, of Montreal, spoke on the coal supply of Canada pointing out that transportation difficulties were an obstacle in the way of sending Nova Scotian coal to Ontario to compete with American coal. The solution of the problem was the deepening of the St. Lawrence canals. E. Stansfield, of Ottawa, discussed the principles and practice of fuel briquetting. A smoker and concert was held in the evening which was largely attended.

C. E. Macdonald on the following day gave an address advocating the use of nickel for the coinage of 5 and 10-cent pieces in place of silver. A discussion on the subject followed which resulted in the adoption of a resolution moved by T. W. Gibson and seconded by A. J. Young of North Bay requesting the Council of the Institute to take the matter up with the Dominion government and enlist the support of members of Parliament. J. G. McMillan spoke on 'Recent Developments in Mining in Northern Ontario', noting the changes brought about by the increase in the price of silver that have rendered it profitable to treat ore formerly classed as waste, and by the general adoption of the flotation process. The following officers were elected: O. E. S. Whiteside, president; E. E. Campbell, W. J. Dick, H. Y. Russell, and D. H. McDougall, vice-presidents.

The annual banquet held in the evening brought the convention to a close, the principal speakers being Harry Mills and Bradley Stoughton, secretary of the American Institute of Mining and Metallurgical Engineers, who brought the cordial greetings of that organization and expressed the hope of closer co-operation between the engineers of Canada and the United States.

The following day about 130 of the members paid a visit of inspection to the new nickel-refinery of the International Nickel Co. of Canada at Port Colborne, returning to Toronto in the evening.

PORCUPINE.—The mining companies have voluntarily increased miners wages in this camp and in Kirkland Lake, the new scale, which goes into effect this week, giving muckers and loaders \$4.25 per day and miners \$4.75, with increases to the mill and surface men. The increase averages about 50c. per day. The prices on goods at the Porcupine mine stores have also been cut about 20%. It is expected that these concessions will considerably relieve the labor situation and attract many needed workers to the camp. The shareholders of the Dome Extension have ratified the proposal of the directors to extend the option held by the Dome Mines to September 15. The terms of the agreement are continued, under which the Dome must spend at least \$3000 per month on development. According to an official statement for the period between the re-opening of the company's mill in June last and the end of December, the Dome treated 187,580 tons of ore, averaging \$7 per ton, with a total recovery of \$1,290,301 or \$6.87 per ton. The Porcupine Crown is making active preparations to resume operations. The mill has been placed in running order and a force of men

has been taken on. There is sufficient broken ore to keep the mill in operation for six months.

KIRKLAND LAKE.—The area of this camp is being considerably extended to the east where a number of new companies are developing claims for several miles beyond the known gold-bearing zone. The geological formation of this new section presents the same characteristics as prevail where the mines are situated, and surface indications are promising. Some mining men are of the opinion that this will finally prove one of the most extensive gold-producing areas in Canada, stretching eastward through Lebel township as far as Larder Lake. At the Canadian Kirkland the shaft is down 180 ft. and cross-cutting is under way at the 150-ft. level. The Ontario Kirkland has opened up a vein of \$20 ore on the 300-ft. level for a considerable distance. The Argonaut, formerly known as La Mine d'Or Huronia, situated on Beaverhouse lake is carrying on development, having proved up a substantial tonnage of commercial ore. Drifting operations are under way at the 200-ft. level, where an ore-body over 100 ft. long has been developed averaging \$9 per ton over a width of several feet. A large cyanide mill will be built.

COBALT.—Hugh Park, manager of the Nipissing mine, announces that during February the company mined ore of an estimated value of \$307,485 and shipped bullion from Nipissing and custom ores of an estimated net value of \$409,523. Regarding development work, he states: "The most important development of the month was the cutting of vein No. 230 by a cross-cut being driven to connect No. 63 shaft and No. 96 tunnel. Two veins were found, within six feet of each other, one being one inch wide and the other two inches. The intervening country-rock contains appreciable amounts of argentite, native and ruby-silver. The veins are not particularly high-grade, but are strong and show fair amounts of leaf-silver and cobalt. The development is important, as the cross-cut is just above the Keewatin contact, which, at this point, is 225 ft. from the surface. A cross-cut 90 ft. higher up and 110 ft. distant also opened milling ore in a disturbed zone, which may ultimately prove to be part of vein No. 230."

Since commencing a new development scheme near the close of 1919, the Chambers-Ferland mine has developed \$150,000 in ore, and is now making regular shipments to the Dominion reduction plant. The Beaver Consolidated is steadily adding to its known reserve of medium-grade ore, as well as mining a small tonnage of high-grade. Mining and milling costs have been reduced to between \$8 and \$9 per ton, or less than 50% of the average mill-heads. During February the Hargraves Consolidated commenced to ship ore, and with a force of 10 men sent out 210 tons of low-grade material, averaging between 12 and 15 oz. per ton. In its lower workings, the Mining Corporation of Canada has installed an electric pump with an automatic starter, by which the several mines of the company are all being kept free from water. An old stope, about 800 ft. long, 9 ft. wide, and 60 ft. deep is being used as a sump to which water from the several properties has a natural flow.

THE MINING SUMMARY

CALIFORNIA

Amador County.—In order to control the fire that has been raging for several weeks in the Kennedy mine, operations today were suspended in the Argonaut mine and the flooding of the property commenced. Work had already been discontinued in the Kennedy and water was started pouring into that mine. In the Argonaut 250 miners have been laid off. In the Kennedy 150 miners are out of work. According to N. F. Kelsey, superintendent of the Argonaut, the two properties face a shut-down of from five to six months. It will take that time to flood the workings, extinguish the flames, and unwater the properties so that mining operations may be resumed.

The fire started in the Argonaut more than a year ago, but was controlled so that work was resumed there. The fire was believed under control and confined to workings no longer used, but recently it burst through into the workings of the Kennedy mine. First efforts toward stamping out the fire apparently were successful until bulkheads put in on the 3100 and 3300-ft. levels failed, and it was found the last resource of flooding the workings would be necessary.

IDAHO

Coeur d'Alene.—The Consolidated Interstate-Callahan Mining Co. proposes to change its name, according to reports issued from the New York office. The title proposed is the Callahan-Zinc-Lead Co. Shipments from the mine since January 1 show improvement resulting from the changes made in the mill last summer. A better separation of the lead and zinc and a closer recovery is being obtained. During January the company shipped 4200 dry tons of zinc concentrate averaging 50% zinc and less than 4% lead. Formerly the lead content was 8 to 9%. During the same months shipments of lead totaled 1600 tons, establishing a new record. The lead concentrate averages about 20 oz. silver. During February some time was lost, but the value of the shipments was higher than in January.

Elmore County.—The Boise Rochester mine, taken over by H. B. MacGowen, is under the capable management of Thomas L. Chapman. The company has spent the past two years prospecting and developing the mine, getting it in shape for operation. Large bodies of ore ranging in value from \$4.50 to \$16 per ton have been exposed for widths of from 10 to 15 ft. A cross-cut tunnel will cut the vein several hundred feet deeper than the old workings. This tunnel is being driven with power-drills, making from 10 to 12 ft. every 24 hours. The new tunnel will open up large bodies of good milling ore and give several hundred feet of backing between it and the bottom of the old workings. The company has been making tests on its ore with the view to erecting a new mill to extract the gold and silver.

The Minerva Mining & Milling Co.'s property is now under the management of C. E. Stevens, trustee. Mr. Stevens has had considerable experience in the Atlanta district and is opening up this mine in good shape. A winze has been sunk from the lower workings, from the bottom of which drifts have been run both east and west for several hundred feet. In the west drift large bodies of ore showing free gold have been exposed.

The Big Lode mine, which has been idle for ten years, is now being operated by the Boston Idaho Milling Co. under the management of W. R. Prentiss, who placed both the mine and mill in active operation within 60 days. This property was worked quite extensively some years ago on the surface and down to a depth of 75 ft., producing some rich ore. The company expects to build a cyanide plant this spring just as soon as weather conditions will permit. The ore contains considerable sulphide in addition to the free-milling gold.

Bailey.—The biggest discovery ever made in this district was reported recently in the North Star mine of the Federal Mining & Smelting Co., which is on the east fork of the Big Wood river, about six miles from here. Arrangements have been made to build a concentrator at the Golden Glow mine. Milling machinery is being bought. The road will be repaired to facilitate the movement of machinery from the railroad to the mine.

MISSOURI

Joplin.—The Metals Extraction Corporation of America, which is equipping a plant for the manufacture of zinc oxide at the Old Rock distillery, expects to have the plant making a product for market by April 15. The furnaces and other equipment will be put into operation a few days before that time, but it is the plan to allow several days for inspection and adjustments, if necessary, to ensure turning out a high-class product. The plant will start with one twin furnace, which will produce about 7000 lb. of zinc oxide per day. Other furnaces will be started later and it is expected by July the plant will be going at full capacity, turning out 80,000 lb. per day. Zinc oxide will be made here under a new process, that is said to greatly reduce the time required under old methods. The process is the invention of A. Schwarz who perfected it during his five years residence in the Joplin district. He says the plant will produce zinc oxide in 30 minutes instead of the many hours needed by old methods.

The plant is being equipped with many labor-saving devices and will be highly efficient when completed. The company is a \$1,200,000 concern, composed largely of New York City capitalists.

The Iowa Mining Co., which has a 46-acre lease two miles south of Baxter Springs, has purchased a 150-ton mill and is moving the plant to its lease. The Iowa lost all its equipment, consisting of engine and boiler-rooms, derrick, hoisting and pumping machinery, when fire broke out in the plant last fall. After adjustments were made with the insurance company the place was cleaned up and new hoist and pumps purchased. The mine is regarded as one of the richest in the district and the shaft now is in a fine body of ore, which is being hoisted and thrown on the dump, awaiting the erection of the mill.

MONTANA

Butte.—At the old Champion mine near Deer Lodge a first-class hoist, mounted on a concrete foundation, has been installed; a new head-frame replaces the old one; shaft compartments have been re-timbered to the water-level; a receiver getting air through a 2500-ft. air-line from the lower tunnel furnishes sufficient pressure to keep the water spouting out of a 6-in. water-column, and furnishes enough power to operate the hoist. The Butte-Jardine company,

operating the property, has purchased and installed more than 80,000 lb. of machinery at the mine. A 150-hp. motor and compressor, one 54 by 16 in. receiver, a large hoist, and an 80,000-volt transformer are included in the equipment at the plant. Lumber is furnished from a saw-mill purchased by the company last fall.

NEVADA

Divide.—The Tonopah Divide meeting has again been postponed, this time indefinitely, because of the illness of H. C. Brougher, president of the company.

Goldfield.—It is reported that the Development company's mill will start on a small tonnage April 1.

Marietta.—Silver ore from 1 to 6 in. wide and assaying more than 6000 oz. has been found in a 30-ft. shaft on the C. & A. claims, 35 miles south-west of the Simon district. A sample taken from a width of two feet gave an assay return of 200 oz. silver, 45% copper, and 5% lead. A shipment of 715 lb. gave a smelter return of \$1.67 per pound.

Pioche.—Practically no deep mining has been done in the district. The deepest shaft is down but 1400 ft. Men who are familiar with the geology and mineralogy of the locality are confident that the possibilities of many of the old mines, with deep operations, are promising. Pioche is taking on new life with the rapidly increasing activity. Shipments have averaged for a considerable period 2500 tons of ore per week. Last week 3000 tons were shipped. The Virginia-Louise has a contract to furnish 1000 tons of ore per week to Salt Lake valley smelters. In order to handle this tonnage economically, officials of the company are in the East arranging for the purchase of new equipment. At the Combined Metals, a large tonnage of silver-lead-zinc ore has been blocked out. The Pioche Mines Co. has taken over the Nevada Volcano mines, which include the Stindt-Donohue and the Big Five leases. Milling experiments on the treatment of the ores of this property are being made by the company at the old Yuba mill near the railroad depot. By mixing the ores mined at the Nevada Volcano property with ores from the Nevada Mines an excellent concentrate can be made.

NEW MEXICO

Santa Rita.—The new mill of the Grant County Copper Co. is being operated, and shipping will begin in the near future. The Chino Copper Co. is working about half of its normal force in the pits; everything is held in readiness to resume work with a full force at any time conditions warrant.

Silver City.—The Silver Spot Mines Co. has its shaft on the Boston Hill down 100 ft. and it has been in iron ore almost from the first. It is stated that shipping of iron-manganese ore could begin at any time, but that it has been decided to continue sinking before any cross-cutting is done.

Socorro.—The Mogollon Mines Co. is shipping silver bullion regularly every ten days or two weeks. A recent shipment of 20 bars, valued at \$35,000, was sent to New York.

WASHINGTON

Northport.—Ore is being shipped regularly from the Electric Point mine. The tramway is being operated continuously throughout the day and the operations in the mine are proceeding day and night.

Okanogan County.—Activity is reported in the Oroville district. The Kaaba is ready to ship ore according to J. W. Douglas of Spokane. The ore, which contains copper, silver, and lead, is improving with depth. The shaft will be continued to 1000 feet.

MEXICO

Cananea.—Hoisting from the 700-ft. level of the Carnegie Lead & Zinc property is now in progress and the mill is running smoothly. Two cars of zinc ore and one of lead and copper concentrates have been shipped.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. F. Stevens has returned to Long Beach, California, from Denver.

D. D. Moffat, consulting engineer of mills for the Jackling porphyry properties, is at Duluth.

Oscar M. Bilharz, of St. Louis, who is sojourning at Santa Barbara, was in San Francisco last Monday.

Bulkeley Wells spent part of last week at Grass Valley, where he is re-opening the old Idaho and Maryland mines.

G. A. Joslin, managing engineer for the Ramshorn Mines Co., has returned to Salt Lake City after a brief vacation in southern California.

R. G. Knickerbocker has been appointed metallurgist to the Messina Development Co. in the Transvaal and has left New York on his return thither.

E. Gylbon Spilsbury has returned from Brazil, where he has spent the last few months in examinations of iron and manganese resources and possibilities of utilizing native coal for reduction.

J. T. Shimmis has resigned his position as mill manager for the Arizona Hercules Copper Co., to take charge of the new mill for the Iron Cap Copper Co., at Copper Hill, Arizona, but he has been retained in a consulting capacity in the concentrating department of the Arizona Hercules Copper Company.

Obituary

Julius Thompson died at Anchorage, Alaska, on February 2. He was born near Milwaukee, Wisconsin, one of the ten children of a Methodist minister. He educated himself and graduated at Lawrence University, Appleton; he sawed wood and did odd jobs, often living on only crackers and cheese, in order to complete his education. He then studied law with a prominent firm at Chicago, and practised law until the Chicago fire of 1871 destroyed his library and office. Then he went to Joplin, Missouri, becoming interested in lead mining and building a smelter. Later he erected zinc-furnaces at Weir City, over the line in Kansas, where the coal was, these being the first zinc-smelters in the district. A severe slump in the price of spelter, when he had several months stock on hand, broke him. He then returned to Milwaukee, and was with the North-Western Mutual Life Insurance Co. for several years, as examiner of titles and abstracts on loans. On account of his health he went to Rico, Colorado in 1880, outfitting with a six-mule team at the terminus of the railroad at Alamosa, Colorado. At Rico he practised law and engaged in mining. In 1892 he helped to sell the Enterprise mine from David Swickheimer to Posen & Crawford for \$1,100,000. He then left the San Juan and became interested in real estate at Salt Lake City, where he lived for a few years. At this time he purchased the Yellow Jacket mine, in Lemhi county, Idaho, which he sold to John F. Searles, of New York, in 1895. The Judge lived at Cripple Creek from 1895 to 1900, when he went to Nome, Alaska, remaining there a couple of years. He presented the indictments against Judge Noyes, who was eventually sentenced to the penitentiary by the San Francisco Court of Appeals. He then moved to Yakataga and Katalla, Alaska, operating some ocean-beach gold-placers at the former. In 1916 he moved to Anchorage, Alaska, the Government town, on the railroad being built by the U. S. Government. The Judge was 80 years old at the time of his death; he leaves a widow and one son, Arthur G. Thompson, an attorney, at Anchorage. In 1864 he married Charlotte Sheldon, at Climax, Michigan.

THE METAL MARKET

METAL PRICES

San Francisco, March 23

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	11.50
Copper, electrolytic, cents per pound.....	18.75
Lead, pur, cents per pound.....	9.50-10.50
Platinum, pure, per ounce.....	\$117
Platinum, 10% iridium, per ounce.....	\$162
Quicksilver, per flask of 75 lb.....	\$90
Spelter, cents per pound.....	10.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

March 22.—Copper is more active and steadier. Lead is quiet and easier. Zinc is dull and erratic.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

The "Commercial & Financial Chronicle", in discussing the foreign exchange situation, says:

"The complete reversal which has come about on the foreign exchange market on the stock market, and in the price of silver bullion at London, is evidence of the change in financial sentiment which the recent incidents have caused. There can be no doubt that a very great number of our own people have for a considerable time been confusing the depreciation in exchange on a given country with impairment of that country's national credit. The two things are not at all necessarily connected. If Western Europe were actually 'bankrupt'—to use the off-hand remark which became so familiar a few weeks ago—or if insolvency were visibly impending, then undoubtedly exchange on Europe would depreciate rapidly. But it does not by any means follow that if exchange on London or Paris is falling violently, therefore England or France must be insolvent or about to become so. The depreciation in exchange may be due, and usually is due, to causes wholly apart from public credit—as it was, for instance, when an exactly similar depreciation in European exchange on New York occurred in August and September of 1914. The United States was certainly neither bankrupt nor threatened with bankruptcy when sterling was quoted at \$7 in August of that year; or, for that matter, when gold sold at 285½ in New York in our paper inflation days of 1864.

"A memorandum of the Supreme Council takes account of these circumstances. It recognizes that the double influence at work on the depreciated exchanges has been the abnormal excess of imports over exports in the recent belligerent States of Europe and the inflation of European paper currencies not payable on demand in gold, and it sets forth as essential that early steps be taken to secure the deflation of credit and the currency, and that this must be done, first through the full resumption of the gold standard, second, through 'suppression of extravagance and reducing expenditure'; and third, through securing 'deflation of credit and currency', alike by reduction of public expenditure to the limits of public revenue and by imposing new taxes where necessary for that purpose, and by immediate limitation and gradual curbing of note circulation."

"That this is a sound conclusion, the actual facts regarding the course of economic events in Europe are evidence. The extraordinary increase in England's export trade, especially to other countries than the United States; the consequent great reduction in her recent yearly increase of imports over exports; the tangible facts regarding the reconstruction already accomplished in the case of the ruined French industries and the resumption of the partly abandoned French agriculture; the failure of all recent efforts at Bolshevism in labor, or at paralysis of European industries through a general strike—these are but a few of the reassuring indications. What is most striking of all, however, is that these signs of increased political, industrial, and economic stability are occurring at the end of a hard winter; which, it had been taken for granted, would test to the utmost the staypower of European institutions under the existing strain."

"A great part of the trouble and delay in doing away with the mischief of demoralized trade and currency inflation in older historic episodes of this sort has arisen from the deliberate refusal of governments, and sometimes of the banking community also, to face the situation either honestly or courageously."

Foreign quotations on March 23 are as follows:

Sterling, dollars: Cable	3.82½
Demand	3.82
Franc, cents: Cable	6.85
Demand	6.93
Lire, cents: Demand	5.90
Marks, cents:	1.38

Eastern Metal Market

New York, March 17.

The markets are all quiet with prices generally lower and demand of small proportions.

Copper buying is light and prices of all sellers are lower.

The tin market is quiet and stale with speculative dealings predominating and consumers uninterested.

The lead market is quieter and barely steady with prices slightly easier.

Values of zinc have been highly erratic under the influence of the London market. Buying is decidedly moderate.

Antimony is quiet and easier.

IRON AND STEEL

Reports from the leading steel-producing centres still dwell on the struggle with short coal-supply and with scarcity of cars and motive power, says 'The Iron Age'. Similar reports prevailed throughout February and yet the official statistics given out in the past week show steel-ingot production in that month averaging 142,000 tons per day, or almost a record rate. The trade is frankly surprised at these figures, in view of existing handicaps.

New activities of labor organizers at various steel-works districts, including Gary, are a subject of comment in the trade and latest strike plans are presumed to centre about May 1. Reports of preparations for a second strike have been circulated for several weeks, but the willingness of workers to repeat so soon their heavy sacrifice of wages is doubted.

The situation as to automobile sheets remains unaffected by the increase in ingot production. Notwithstanding various reports the Steel Corporation still adheres to the finished-steel prices of March 21, 1919.

COPPER

Demand continues light and inducements are necessary to promote buying. Quotations have further receded until now electrolytic copper is quoted by first and second hands, large and small producers, at 18.25 to 18.37½c., New York, for deliveries up to July. One large seller remarked yesterday that unless one really wanted the metal he would not advise an offer of 18c., New York. Lake copper is quiet and easy at 18.37½c., New York. Outside buying is extremely light, but there is an under-feeling of confidence that a buying movement will appear soon to meet the needs of consumers for May-June and perhaps later deliveries. Analysis of the 1919 copper export shows that the total was 438,165,800 lb., or only about 40% of the peak of the war movement in 1917, and less than 50% of the exports of 1913, namely, 926,241,000 pounds.

TIN

The market is flat, dull, and stale and has been all the week. It continues to have a highly speculative nature and all the transactions have been between dealers and traders, consumers still remaining aloof. As soon as the latter come in as buyers the speculative phase of the market will probably disappear. These speculative dealings have been put through irrespective of actual values and conditions. It is believed that spot tin is more concentrated and in stronger hands with the cheap sellers being gradually eliminated. Spot is sold as high as 63.75c., New York, in the week, but yesterday had fallen to 62.25c., New York, due partly to a decline of £11 10s. per ton in the London market, which continues highly speculative. Today the London market fell another £14 to £358 per ton. Yesterday spot Straits was quoted at £372 per ton, which contrasts with £411 two weeks ago and £418 as the high mark a little earlier. Arrivals thus far this month have been 1035 tons, with 5085 tons reported afloat.

LEAD

The market is quiet, dull, and barely steady, with quotations slightly lower, due to easier conditions obtaining in the case of a few producers. While most producers are still striving hard to obtain enough lead to meet contracts, some others are less pressed. There were offerings yesterday of prompt shipment from the West at 9.37½c., New York, which we quote as the market. More metal is being offered for April and still more for May shipment. There is also more lead in transit available as well as some re-sale lots from consumers. There is definite evidence now that increased production is being felt. The London market is receding, quotations being off £2 yesterday from the day before and prices are considerably lower as compared with those a week ago. On March 9 spot lead was quoted in London at £50 5s. and futures at £53. Yesterday these positions were £45 and £47 per ton, respectively.

ZINC

Prices have been erratic all the week and often each day, values in the morning often being at great variance with those later in the day. This has been due largely to conditions in the London market where speculation is a big factor. On the dip in values about a week ago there was a fairly large amount of buying by domestic consumers and by exporters. This quieted down as the week advanced until now the market is quiet and inclined to be easy. Yesterday prime Western for shipment up to July was obtainable and offered as low as 8.50c., St. Louis, and 8.85c., New York, which we quote as the market, but sales by one producer of prominence were made at 8.60 and 8.62½c., St. Louis, or 8.95 and 8.97½c., New York, for fairly early shipment. There is only a fair demand for either foreign or domestic account. Japan is largely absent as a factor.

ANTIMONY

The market is quiet and lower, due to less demand and the appearance of some re-sale lots. Wholesale lots for early delivery are quoted at 11 to 11.25c., duty paid.

ALUMINUM

Virgin metal from the leading producers is held at 33c., New York, for wholesale lots for early delivery. From outside sources it is quoted as low as 31c.

ORES

Tungsten: The market is inactive and apparently awaits some action on the tariff, although some insist that the bill will never become a law. Quotations range from \$6.25 per unit for Chinese ore to \$15 for high-grade domestic ore.

Ferro-tungsten is obtainable at 80 to 90c. per pound of contained tungsten.

Molybdenum: Only a little business is reported, with values at 75c. per pound of MoS₂ in regular concentrates.

Manganese-Iron Alloys: Domestic producers of ferro-manganese have advanced their prices to \$180, delivered, for last half. Before this some 2000 tons was sold for delivery in March and later, all domestic alloy, part of it from a recent new producer. For the March business \$230, delivered, was obtained, a new high figure since the Armistice. For second quarter \$200 was the figure and for later and last-half business around \$175 was obtained. Almost no British alloy for any delivery is now available. On a recent inquiry from California for a few hundred tons a British maker bid \$212, delivered, but the business was not considered. The spiegeleisen market is stronger at \$60, furnace. While domestic demand is light just now, foreign business is large, there being from 15,000 to 20,000 tons under negotiation.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE WELLMAN-SHAVER-MORGAN COMPANY RAILWAY CAR-DUMPER

Car-dumpers are employed for discharging the contents of open-top railroad cars by inverting the car sidewise and dumping the contents into boats, bins, or storage yards. Car-dumpers may roughly be divided into two general classes—the turnover type, which does not lift the car except to turn it about on axis, and the lifting type, which elevates the cars for discharging direct into vessels or into high storage-bins. The turnover type has been developed in

movable car-dumpers, while the stationary turnover-type is operated by steam or electricity as preferred. Most of the lifting type of car-dumpers are operated by steam, although some installations have one or two of their functions electrified. There is at present a growing tendency toward complete electrification of this type on account of greater operating economy. It is not, however, always convenient to produce or secure the necessary electric current and then great economies may be secured from steam operation. If electric power is used it is always direct current. During

Dumper for Standard Railroad Cars

stationary and moving machines. Recent models overturn and dump two railroad cars at once.

All types consist essentially of a rectangular framework supporting a rotating cradle in which the loaded railroad car is held while discharging. An entirely automatic counterweight device clamps the car to the cradle which is inverted by the revolving mechanism, carrying the car with it. The top of the cradle forms a chute for directing the material as it flows out. While most of the recent installations have been electrically equipped, car-dumpers are built for either steam or electric operation. The stationary turnover car-dumper usually is employed in connection with transfer cars or other conveying devices. The moving car-dumper propels itself along the dock or edge of stock-yard, rendering unnecessary the use of transfer cars or conveyors. The stationary lifting car-dumpers are usually employed for discharging cars directly into boats, or into elevator bins.

Electric power is used exclusively for the operation of

the operating cycle in all types of car-dumpers the electrical equipment is required to handle high peak-loads and constantly varying power demands, as well as dynamic braking when lowering the car after its contents are discharged. Great delicacy of control is required, through wide speed variations, and absolute safety must be maintained against current failure.

Direct-current equipment possesses all the necessary requirements for such operation, the motor-torque characteristics being ideal and the control easily lends itself to the arrangement necessary to produce dynamic braking, slow-downs, cut-outs, and limit switches, which are essential to satisfactory car-dumper operation. The speeds of a car-dumper are usually regulated to produce a complete cycle in 1½ to 2 minutes or about 30 to 35 cars per hour, and under certain favorable conditions this capacity is far exceeded for short intervals. A notable performance appears in the handling records of one of the large coal-piers on the

Atlantic coast. This pier is equipped with two W-S-M car-dumpers which, in one day, dumped 930 cars having an aggregate of 45,500 tons at an average rate of 1 1/2 minutes per car.

THE PROBLEMS OF THE RAILROAD COMPANIES

Seth Mann, traffic manager of the San Francisco Chamber of Commerce, appeals to shippers to be patient with the railroad companies until they have had time to readjust their organization after more than two years of Government control. He says that the first year after the return of the railroads to private control will be one filled with difficulties and obstacles to be met by the private carriers. It may be fairly anticipated that for at least a year they may not be able to furnish a transportation service equal in efficiency to the Government service. The public should be prepared for this emergency, and the carriers should adopt a new attitude toward the public which will keep them informed of existing conditions. Failing in this, the public demand may swing back to public ownership. An efficient and competent transportation service must be furnished. On the whole, competition in service produced better service than the Railroad Administration has been able to give. It remains to be seen whether the private owners can excel the Government administration in the future. The shippers of freight are convinced that the dangers of public control far exceed any disadvantages attaching to lack of uniform or consolidated operation under private management. On the other hand, they look forward to the return of competition and the control of the various systems of railroads by the respective private organizations of expert railroad managers as an immediate solution of the transportation question. The re-establishment of effective transportation systems out of the welded system of the whole country is complicated at once with hundreds of problems never before met in the history of railroads. These problems cannot be solved in a day or a month, or perhaps in years. It is during this time that the public should be patient. Some of these problems requiring time for solution concern the insufficient car supply. There should develop a new kind of railroad publicity and a new attitude of officers and employees toward the public. The public should be kept informed of the difficulties of reorganization and of the progress made and the plans for the future.

COMMERCIAL PARAGRAPHS

Bulletin No. 110, issued by the Metric Metal Works of the American Meter Co., Erie, Pennsylvania, outlines the principle of the orifice-type of meter for gas, air, or steam, and describes the various manufactures of the company. Differential gauges are likewise discussed.

'Grinding Data, No. 2' has just been issued by the Hardinge Conical Mill Co. Detailed results of tests at the Nevada Consolidated concentrator at McGill, and at the plant of the Arizona Copper Co. are given. This pamphlet is the second of a series published to advertise the Hardinge mill and present to those interested new data regarding grinding problems.

The Drake Lock-Nut Co. is smoothing out the way for trade relations with the foreign buyer. Geo. F. Drake, vice-president and general manager of the company, has worked out a plan enabling him to quote c.i.f. for any large seaport in the world. A buyer in Johannesburg, Buenos Aires, or Singapore may now know exactly what Drake merchandise will cost him landed at his seaport.

H. R. Wahl & Co., engineers, 1218 First National Bank Bldg., Chicago, have recently published an attractive catalogue on the Wahl dewaterer. This catalogue goes into detail regarding the performance of this device and is fully illustrated. H. R. Wahl, the inventor, was for a number of years connected with lead-mining companies in south-eastern

Missouri and the Wahl dewatering device is the result of a great many years of experience in milling practice.

The Allen Cone Co., engineers of El Paso, Texas, has issued Bulletin No. 14, which describes the method of utilizing the Allen sand cone in closed circuit with a ball or tube-mill. The principal advantages from the metallurgist's standpoint are the large capacity and the small floor-space required. Simplicity is another feature of the cone which merits consideration.

Ray T. Middleton has resigned as general sales-manager for the Standard Steel Castings Co. of Cleveland to become vice-president and director of sales and advertising for the Kelly Metals Co. of Chicago, Detroit, and Los Angeles. His headquarters will be at Chicago, where the Kelly Metals Co. will, at an early date, establish its principal production plant. The company will continue its present plants in Detroit and Los Angeles and later establish a third branch plant, at a point to be selected in the East.

The regular quarterly meeting of the gold-dredge operators of the California Mineral and Metal Producers' Association was held in San Francisco, March 15, the feature of the gathering being a visit of inspection to the Union Iron Works plant of the Bethlehem Shipbuilding Corporation. During this visit George Hurst acted as host, and also presided at the luncheon served the visitors at the plant. The dredge operators saw, among other things, thirty destroyers under construction. These vessels, each driven by four turbines, will develop 28,000 hp. and a speed of 36 knots per hour. The floating drydock, in which a 10,000-ton ship was cradled, was another point of interest. In conclusion Mr. Hurst showed his guests two electrically-welded pontoons for the No. 5 Marysville dredge. These pontoons were constructed without rivets. The next meeting of the dredge operators will take place at Natomas.

An insurance policy for the sum of \$500 will be given entirely without cost to every employee of the Westinghouse Electric & Manufacturing Co. who has been in the service of the company for a period of six months or more. In addition, the employees, after April 1, may increase the value of their policies to amounts varying from \$1000 to \$2000, depending upon their length of service and continuity of savings. All employees who have been in the company's service for six months or longer and who deposit a sum each pay-day in the Employees' Savings Fund, equal to 2% or more of their earnings, will not only receive 4 1/2% interest compounded semi-annually on such deposits, but in addition will automatically have their insurance increased to amounts up to \$2000, depending on the length of time they have been with the company. After five years deposits may be withdrawn without affecting the value of an employee's insurance.

In keeping with its policy to render the most efficient service possible to present and prospective owners of motor trucks, the Garford Motor Truck Co. of Lima, Ohio, has established a new department, the duties of which will be to gather authoritative information on the operation of motor trucks and to aid present owners to obtain the lowest cost per ton-mile. This department will investigate the operation of Garford motor trucks in all parts of the country, obtaining data relative to the operating costs in actual service. In each case an exhaustive investigation will be made of every detail entering into the operation and maintenance of the trucks in use, including problems in loading and routing, methods of delivery, housing, repairing, and driving. Much study will be given to the kinds and quantities of loads hauled, the distribution area, the grades and the conditions of highways, the climatic conditions, the frequency of stops, the speeds which may be maintained in conformance with conditions and State and town laws, in fact every item which has any bearing upon truck operating and maintenance.

T. A. RICKARD, . . . Editor

SHADE of metalliferous Murphy! The following description of a queer specimen of copper ore has been sent to us from Salt Lake City: "The original wood of the tree branch has been replaced bit by bit with copper—a form of replacement which is technically known among geologists as a 'pseudo-murph,' " Bagorrah, an' phat duz yez t'ink av thot!

SPEAKING of 'lives' of Mr. Hoover, of which several have been, or are being, printed in the current magazines, we recommend our readers to get copies of the 'Sunset Magazine' published in San Francisco. In the March issue and in succeeding monthly issues they will find an account of Mr. Hoover's life and career by Rose Wilder Lane and Charles K. Field. Mr. Field is the editor of the 'Sunset' and was a classmate of Mr. Hoover at Stanford University. He and Miss Lane are writing what promises to be the most accurate and the most interesting description of Mr. Hoover and his work.

AMONG the items of news that may be considered important if true is the announcement, by the American Central Committee for Russian Relief, in New York, that "two valuable goldfields have been discovered in the Urals". It is stated that one of these lies 30 miles north of Ekaterinburg. The position of the other one is left to be placed in accord with the average man's meagre knowledge of Russian geography; so we shall suggest Ufa or Orenburg as points of departure. We are told, by the same committee: "Engineers have reported that if machinery were available these fields would make it possible to increase Russia's gold output by 60% within two years". As to that, we would like to know what the Russian output is; conceivably it may have so diminished, thanks to bolshevism, that an increase of 60% would not be beyond the capacity of one ordinary mine. The Ural region has been relatively unimportant as a source of gold during the last decade, so that any genuine revival of activity would be welcomed. However, relief for Russia is not likely to come so much from the discovery of gold as from the re-discovery of sanity as a guide in political affairs.

AT the end of 1919 the visible supply of gold in the world amounted to \$9,080,000,000, of which the United States held \$4,454,650,000, Great Britain \$1,113,065,870, France \$1,115,585,000, and Spain \$484,475,000,

the remainder being distributed among the smaller nations. The world's total production of gold up to 1919 is estimated at \$16,136,500,000, which leaves about six billion dollars unaccounted. It is believed that a quarter of this has disappeared entirely and that most of the other three quarters has gone into industry and the arts. Since the War the ratio of paper currency to gold has increased enormously. In 1913 the proportion of gold in the United States to other money and checkable deposits stood at 18%; in 1919 it fell to 11%. Thus the expansion of credit showed an increase proportionately greater than that of the gold base. Now that the flow of gold into this country has been checked, the excess of paper credits is being felt, with an inevitable rise in the prices of commodities. The volume of credit has expanded until the gold basis is becoming inadequate; the only remedy is the production of staples and other essentials of life.

TAX-PAYERS generally will have read with keen interest the recent publication of statistics concerning the growth of bureaucracy at Washington. During the War there was some excuse for it; now there is none. In April 1917 there were 37,908 civil employees in the service of the Government in the District of Columbia; at the date of the Armistice the number had increased to 117,454; today there are 100,120 departmental employees still at Washington. The worst exhibit is made by the Treasury department, which had 8285 employees on the eve of the War, and now has 38,140, which is actually an increase of 8798 since November 11, 1918. Several hundred acres of temporary buildings continue to be occupied by an army of workers, a large proportion of whom, says the chairman of the House Appropriations Committee, have little, if anything to do. Taking the country at large, a similar condition of extravagance appears to prevail. Before the War the Government had 500,000 civil employees on its payroll; today it has 726,369. It is time a large part of them were released for productive labor. A billion dollars can be saved, it is estimated, by doing so. It ought to be saved. We suggest the propriety of making a diminution in the number of Federal employees before the election.

DISCOVERY as a pre-requisite to the valid location of a mining claim has been emphasized in a recent decision of the U. S. Supreme Court, in the case of Cole v. Ralph. This case dealt with a dispute at Copper

Canyon, near Battle Mountain, Nevada; it came before the Supreme Court on a writ of certiorari, the Court of Appeals having previously reversed the lower court. The Supreme Court holds that location confers no right in the absence of discovery, both being essential to a valid claim. Section 2332 of the U. S. Revised Statutes provides that possession and work on a claim for the statutory period of limitations is the equivalent, for patent application purposes, of a location regularly initiated, but does not excuse the necessity of a valid discovery. Nor does performance of assessment work take the place of discovery; if occupancy by the explorer is relaxed or is merely incidental to something other than a diligent search for mineral, and another enters peaceably, and not fraudulently or clandestinely, and makes a mineral discovery and location, the location so made is valid. A location based upon discovery gives an exclusive right of possession, and, so long as it is kept alive by performance of required annual assessment work, prevents any adverse location. To sustain a lode location the discovery must be of a vein or lode of rock in place bearing valuable mineral, and to sustain a placer location it must be of some other form of valuable mineral deposit, such as scattered particles of gold in the softer covering of the earth. Thus do the learned justices try to reconcile legislative dicta with geologic conditions.

AT the recent annual meeting of the Exploration Company, in London, Mr. R. T. Bayliss made some interesting remarks on the state of affairs in Mexico. He said that while at the moment conditions could not be said to be better than they were a year ago, he believed that they were going to improve. "There is an indication," said Mr. Bayliss, "of a desire for peaceful reconstruction from within, and a determination that order and good government must prevail in Mexico from without—that is to say, on the part of the people of the United States." However, he did not expect that much, if anything, would be done by the administration at Washington until after the inauguration of the new President next March. There was no suggestion that any departure from the policy of watchful waiting would involve armed intervention on the part of the United States, for that, said Mr. Bayliss, "would be the greatest calamity that could overtake peaceful alien traders like ourselves". With this expression of opinion we agree, as our readers are aware. War would stop all foreign mining operations in Mexico for several years, and, what is much more important, it would involve the United States in a territorial expansion that would be highly injurious, for many reasons, more particularly the possibly necessary assimilation of a large alien element at a time when this country is suffering from political dyspepsia. Mr. Bayliss suggested, again, the creation of an international commission, co-operating with the United States. It should not be beyond the capacity of diplomacy to institute good government and order in the conduct of Mexican affairs "and so to place it in the position of prosperity to which it is entitled, by its geographical position,

its climate, and its abundant resources". This is more than a pious wish; we feel sure that a man and an engineer of such proved sagacity as Mr. Bayliss can do something toward hastening the consummation of hopes so long deferred.

Who's Hoover?

At the present time, naturally, there is a lively curiosity concerning Mr. Hoover. We received a letter from the superintendent of a mine asking us to publish "a short biographical sketch of Herbert Hoover". Our correspondent explained that he was being asked daily "Who is Hoover?" He himself knew enough about the man of the hour to be able to meet the local demand with a few facts, but his fund of information was inadequate, so he tells us. We quote from his letter: "They [some of the mining community] went to town Sunday last. Monday morning I was greeted at the mess-house with 'Say, ain't it hell about Hoover?' 'What's hell?' I asked. 'Why he's an Englishman and he can't run for President!' 'Who is the liar that told you that', I asked, and hustled back to the office for the 'M. & S. P.' of the 7th last, and read 'The Hoover Boom' to them while they ate their hot cakes, and they went up the hill much relieved." We give this verbatim. He refers to our issue of February 7. In his letter to us he asks for particulars of Mr. Hoover's mining activities, especially in his earlier days. We are glad to comply with this request, which we have reason to know voices the desire of hundreds of our readers. So we publish a biographic sketch on another page. Mr. Hoover worked as a miner in this State, but soon ceased thumping a drill or swinging a shovel, because he was ambitious and intelligent, and therefore wanted to engage in the engineering work about a mine, for which his education had been a preparation, however inadequate that education or any other college training may be. He went to Louis Janin for employment and was engaged as an assistant. A story in the magazines says that he was asked by Mr. Janin to do typewriting and that he agreed to do so, buying a machine and teaching himself to use it within two or three days. This is apocryphal. The story is foreign to Mr. Hoover's character; he never was a bluffer nor does he deal in such cheap stuff. While with Mr. Janin he examined mines in several western States, including Colorado, New Mexico, and Nevada. He did so well that his chief recommended him for an attractive appointment in Western Australia. Mr. Hoover went abroad for the same reason as many other leaders of our profession, namely, because he was so competent that his services were in demand. The present writer met him in Western Australia in 1897. He was then only 23 and looked even younger, but he was a man among men, intelligent, keen, quiet, and resourceful. That part of Australia was enjoying a boom and the hotels were cluttered with half-baked engineers and fakers of various kinds. It was a relief to meet the young engineer from California and to discover that he could 'deliver the goods', that he knew what he was about, and that he could be trusted to do it up to the hilt. The

articles in the magazines, notably those in 'Everybody's', the 'World's Work', and the 'Review of Reviews', are written by men unfamiliar with mining, so they contain a lot of nonsense. They say he "located" one of the richest mines in Western Australia, that he introduced a wonderful "new process" for the extraction of gold, that "the ore occurred in the rock in a manner different from that in any other known goldfield", and so forth. This is rubbish. It was because the conditions resembled those with which he had become familiar during his short but intensive experience in our West that he was able to direct operations effectively and to appraise mines successfully in Western Australia. He had learned, under Janin, how to sample mines and how to weigh the factors that determine the present value of a mine. He knew more about the essential elements in the daily problems presented to the mining fraternity at Cue, Coolgardie, and Menzies than men twice his age. He was intellectually honest then, as now. He knew how to select assistants then, as now. He was a hard worker, wasting no time on frivolities, but going straight to the mark. His success—given health and opportunity—was certain. It proved phenomenal. Before he was thirty he was in charge of enormous operations and receiving an immense salary, which he earned—every bit of it. In course of time he became a partner in the English firm with which he was first connected in Western Australia. He went to London and after a few years opened an office on his own account.

He was one of several score Americans connected with mining operations controlled from London; for London was still the centre of mining in its world-wide aspect. Other American mining engineers went to South Africa and made fortunes. Some of them lived at headquarters with offices in the same building as Mr. Hoover. During the two decades between 1895 and 1915 the American mining engineer as a type came into his own; he had proved his ability and was engaged by European financiers and directors, by the British, the French, and the Germans. It is a noteworthy fact, however, that not one of them changed his citizenship by naturalization. None of them even thought of doing so; nor, it is fair to add, were they ever asked to do so. They lived for ten or twenty years away from home, but they always expected to return to God's country. As for Mr. Hoover, he was "as American as baseball or corn on the cob". Mr. Will Irwin said that and it was well said. Both of us saw Mr. Hoover at work in London and know how bluntly, uncompromisingly, outspokenly American he was at all times. To suggest that he adapted himself to his British environment or abated any of his Americanism must amuse the Europeans with whom he had to deal in later years. Despite a lack of suavity and of those little amenities that are prized in Pallmall or the Faubourg, he won the esteem of the men with whom he was engaged in mining operations. He won their esteem and their confidence. This was proved strikingly only a few months before Germany started the War, when a group of companies became involved in a scandal owing to the

misdirection of affairs by the chairman, a man belonging to an aristocratic and distinguished family. His bankruptcy and the exposure of gross mismanagement created a shock in the city of London. His co-directors were in serious difficulties and became anxious to regain public confidence by selecting a new chairman that would restore the morale of their enterprises, one a gold mine in Colorado, another a silver mine in Mexico, and a third a copper mine in the Transvaal. They selected Mr. Hoover, who was not a director of any of these companies and held no shares in any of them. It was a striking tribute to his public reputation as a technician, financier, and administrator. Since then he has done so many bigger things that this episode has become of minor importance, but to the profession it will have a permanent value because it established his standing in mining affairs. Before the War, Mr. Hoover ranked among the first six mining engineers in the world and we could not with any confidence select more than three others out of the six. He was at the very top of his career as an administrator of mines at the time when, at the beginning of the War, his public and patriotic spirit drew him into larger work and vaster responsibilities. He is only 45 now. He has refused decorations by the score, but he did accept the title of the First Citizen of Belgium. When King Albert was in San Francisco and was being entertained at a public luncheon, the name of Hoover was mentioned by the chairman, whereupon the King stood up, in recognition of the fact that Mr. Hoover was the First Citizen of Belgium. Shall his own countrymen do less? Let us elect him First Citizen of the United States.

Report of the Industrial Conference

In our issue of January 10 we gave an outline of the preliminary recommendations of the Industrial Conference convened by the President at Washington on December 1, 1919. On March 20 this Conference issued its final report, and it is remarkable how little attention the daily press has given to it, although it is an earnest and intelligent effort, by a number of particularly competent men, to evolve a scheme for diminishing the troubles arising from the conflict of interests in American industry. The conferees, in their report, start by affirming that the place to prevent misunderstanding is where it begins, namely, in the plant itself, and therefore the first step should be the joint organization of employers and employees with a view to making a collective agreement by mutual understanding and concession. In default of such agreement, the Conference proposes a system of settlement under governmental encouragement. The scheme, in the main, follows the outline made known on December 29. It consists of a plan, nation-wide in scope, the chief feature of which is the establishment of regional adjustment conferences co-ordinated with a National Industrial Board at Washington. This Board is to consist of nine men appointed by the President. The regional conferences are to consist of two representatives of each of the disputants and four others

in the same industry to be chosen by them, with a presiding officer nominated by the Government, this chairman being a trained official able to play the part of a conciliator. In case of failure to agree, the dispute goes to the National Industrial Board, unless the parties to the controversy agree in preferring to submit the matter to an umpire to be selected by them. Voluntary submission of a dispute includes an agreement by both parties not to interfere with production pending adjustment. If either party, or both, refuses to submit the dispute to this process of adjustment, the regional chairman is empowered to call into conference with him two employers and two employees detached from the dispute but engaged in the same industry. The conference so organized will then make an inquiry and publish its findings, for the purpose of guiding public opinion. The whole idea, therefore, is to encourage a reasoned discussion of grievances, to adjust them if possible, and, if not, then to place the facts before the country so that the weight of public opinion may make itself felt. Here the question of the character of the local press obtrudes; the creation of a healthy public opinion is vital to the operation of any such scheme, as it is to the enforcement of all salutary legislation; the influence of a debauched press, like that of San Francisco, is lamentable because it does not place the facts before the public or else willfully distorts them so as to render intelligent opinion impracticable. For instance, the important report that we are discussing has not appeared in any of the three local papers that we have to read daily. The plan, as outlined, it will be seen, imposes no penalties except public condemnation, nor does it impose compulsory arbitration; it does not deny the right to strike, nor does it submit to arbitration the rival policies of the 'closed' and 'open shop'. Its main purpose is to facilitate settlement by discussion and the enlistment of public opinion in enforcing a settlement once the points at issue have been made clear. Prevention of disputes is worth more than cure. One of the chief causes of misunderstanding is the loss of personal contact between employers and employees due to the growth of industrial operations. In order to cultivate the right, that is the humane, relationship between capital and labor, between managers and workmen, it is necessary to organize that relationship deliberately, within the plant, thereby enlarging the unity of interest and diminishing the area of conflict. Experience has shown that where the joint organization of management and workmen is undertaken with sincerity and goodwill, it has succeeded in establishing friendly relations. It has worked well under union agreements, in non-union plants, and in those in which union and non-union men work side by side. Of course, the chief difficulty will be the selection of representatives by the employees without fear or favor from the employer. The selection should be made by secret ballot and there must be no discrimination by the management against the members of the shop committee. There will come the real test of sincerity on the part of the management. As to collective bargaining, the Con-

ference "sees in a frank acceptance of this principle the most helpful approach to industrial peace", but any successful, that is, fair, application of the principle must rest upon good faith on both sides. The Conference says: "It is fundamental that the basic wages of all employees should be adequate to maintain the employee and his family in reasonable comfort and with adequate opportunity for the education of his children. When the wages of any group fall below this standard for any length of time the situation becomes dangerous to the well-being of the State." As to profit-sharing, the Conference says that while it has "promise in some directions, it cannot by itself be considered to be of far-reaching effect". In conclusion, the report states that the suggested reforms are urged "not with any feeling of panic, but with the belief that they will not only contribute largely toward the elimination of the causes of industrial strife, but that they will make for the introduction in American industry of those democratic principles which constitute the most precious heritage of the American citizen". To that we subscribe most sincerely; the report shows a spirit that is humane, democratic, American; it does honor to the members of the Conference and more particularly to its acting chairman, Mr. Hoover, whose ideas, and even phrasing, can be detected throughout the report. The recommendations were unanimous, says Mr. Hoover. He states also that collective bargaining was adopted by the Conference "as a policy, but not as a principle". On page 508 we quote further remarks made by him on the subject. Mr. Samuel Gompers, we regret to note, strikes a dissentient note; he asserts that the machinery devised by the Conference is no improvement upon the means already available and "worked out through long experience by organized workers and employers". Indeed, he is of the opinion that the machinery of adjustment already existing is superior to that suggested by the Conference; he objects more particularly to the settlement of disputes shop by shop, emphasizing the point that the independent shop unit is "a menace to the workers, for the reason that it organizes them away from each other and puts them in a position where shop may be played against shop." He concludes with a defiant note: "American labor understands, perhaps more fully than do American statesmen, the needs of the world in this hour, and is exerting every effort to see that those needs are met with intelligence and with promptness." What the captains of industry think of the report, we do not know; but it is more than probable that some of them will not like it. We do believe, however, that the public generally will accept the proposals of the Conference as just, practicable, and therefore wise. The aim obviously is to prevent if possible the extension of trouble from any one plant to other plants, leading thereby first to a sympathetic strike in an industry, and then to a general strike throughout the country, as has been threatened more than once. What a general strike means we have seen lately in Germany: it means revolution, nothing less; it means defiance of the Government; it is the suicide of democracy.

Mining in the Philippines in 1919

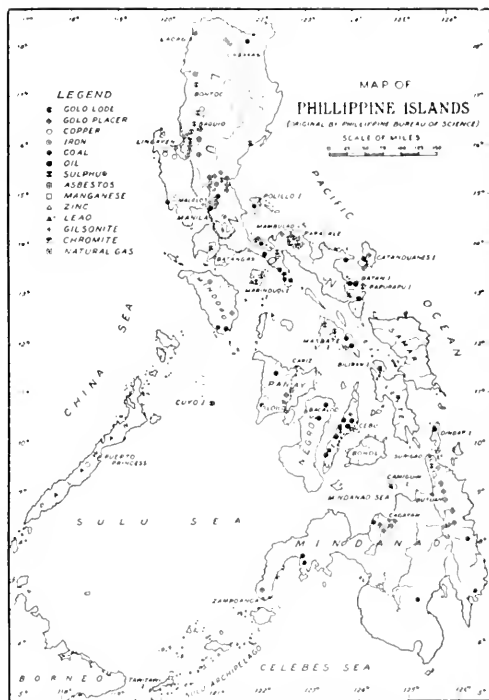

By C. M. EYE

In common with most localities, the year was not a favorable one for mining in the Islands, owing to the greatly increased costs, unsettled industrial conditions, lack of adequate transportation facilities, and uncertainty as to the future. In gold mining, which leads other branches, there was a marked falling off in production, owing principally to the closing down of most of the dredges (operating for the most part in the Paraale district), in some cases due to actual exhaustion of available areas, and in others to the advance in costs beyond the point where operation at a profit was still possible. No definite figures on the total gold production for the year are available at this time, and it will be more difficult than usual to get full returns, as the substantial premium on gold that prevailed locally resulted in many of the smaller producers selling directly to dealers. As there is a bullion tax (of 1½%) in force, the Bureau of Internal Revenue should have figures covering the regular production pretty accurately.

The three principal gold mines of the Islands, namely, the Colorado and Syndicate of the Aroroy district, Masbate island, and the Benguet Consolidated of the Benguet district, island of Luzon, all maintained a steady output during the year, the two former at about the same rate of production as heretofore, and the latter at an increased rate. At all three larger tonnages were treated than formerly, but at the first two the grade of ore was lower. All three were able to operate at a profit, however, in spite of increased costs, the Benguet Consolidated making the best showing, thanks to a mill-feed of \$20 per ton. The Colorado paid a 5% dividend in June (with a possibility of another in December), while the total dividends for the Consolidated will amount to at least 35% on the capitalization of half a million dollars. (Capitalization of the Colorado is the same.) As regards costs of operation, all three mines buy most of their supplies in the States, but the expense, owing to high first cost and high freight-rates, was much greater than heretofore. The Aroroy mines are favorably situated as regards local transportation, being near the sea, but they suffered most heavily from increased price of fuel-oil, on which they depend almost altogether for power. The Benguet Consolidated has an advantage in having its own hydro-electric power-plant, furnishing power for less than a cent per kilo-watt, but has to stand a charge of about \$20 per ton on freight from Manila to the mine. Labor cost did not show as stiff an advance as that for supplies, nor any such ratio of advance as in most mining districts. The price of rice advanced during the year, and as this is the staple food of the workmen, this increase affected local economies considerably. The Benguet Consolidated has always maintained a system of rationing its employees,

which minimizes any such effect, and has the result of securing more steady service than is otherwise possible.

As silver production is limited to that recovered in combination with gold in bullion, there cannot be said to be any silver-mining industry in the Islands. The same may be said of the mining of lead, zinc, and copper, in so far as any actual production is concerned. There is no local smelting industry, and if any base-metal ore was exported, the amount was negligible. During the years

immediately preceding 1919, some exports of manganese ore were made from a property on the west coast of northern Luzon, and some from other localities, to Japan, under the spur of war prices, but I am not aware of any having been made in 1919. The most notable development was the taking over of a large deposit of limonite ore at Mambulao, in south-eastern Luzon, by a Japanese company, and the start of regular operations of mining and shipping to Japan by a line of steamers owned by this company. This should develop into an important business, profitable to the Philippines, which are best adapted to production of raw ores, and to Japan, which is in need of them. This observation will apply to the possi-

ble production of raw ores from certain known deposits of the base metals in Mindoro and elsewhere, though these it may be found possible to ship to Pacific Coast smelters, in case return-freight rates become normal again. Since local conditions preclude local smelting, the hope lies in being able to produce ores of a grade suitable for export.

Prospecting has practically ceased, in the commonly accepted meaning of the term. No new districts are being opened up, and few extensions were made in known districts last year. While Filipino capitalists are fairly ready to invest in going concerns, they do not take to the business of discovering and developing prospects. The principal developments have been on properties already extensively explored, and taken over on bond. Notable among these is that of the Manayan copper deposit in northern Luzon, by Philip Whitaker, financial representative of certain Catholic orders, the Acupan mines of the Benguet district, by A. S. Wheeler, representing English interests, and the Demonstration mine, near Baguio, in Benguet, by a Chinese syndicate of Manila, represented by Victor Lednicke, formerly Chief of the Division of Mines of the Islands. On all of these properties, development is said to be proceeding satisfactorily, and I venture the opinion that there are a number of other known deposits in the Islands that fully warrant the expenditure of capital for judicious exploration, provided they can be bonded on reasonable terms and for a sufficiently long period (say, two years in most cases) but with a provision for continuous work. It is a notable fact that the producing mines mentioned in this article were proved with comparatively small expenditure prior to operation, and there is no doubt that, given sufficient time, a great deal can be done with a comparatively small capital, in this way, but the common mistake has been made to try to make a prospect pay its way by beginning small-scale operations before the mine has been sufficiently developed. If these precautions are observed, I am of the opinion that the Philippines offers a good field for those who are seeking new producers, especially of gold.

The outlook for placer mining does not appear to be as favorable, for the known deposits at river-mouths seem to be nearing exhaustion, and while there are reported extensive gravel deposits where certain gold-bearing streams debouch on the coastal plains, these are both difficult to check by testing, and will be more difficult to work by dredging than the deposits heretofore handled. Nor is the grade of these gravel deposits likely to be as high. However, they may warrant thorough investigation in some cases.

It is to be hoped that something will occur to stimulate the mining industry in the Islands beyond that of the already operating producers, or the business will soon show a further decline. Of the three regular gold producers, the Benguet Consolidated was the only one that showed a material increase of production over former years, and this was due mostly to the tonnage having been increased from about 60 tons per day at the beginning, to around 80 tons during the last months of the year. The produc-

tion, which was about \$30,000 per month at the beginning, was increased to over \$40,000, that for October being in excess of \$50,000. This mine has several years supply of ore blocked out, of the grade indicated, all above the drainage-level, and has no indications on this level of diminution either in grade or extent of the ore-bodies; so it has considerable possibilities for the future, but nothing has been proved below the water-level. A three-compartment vertical shaft is now being sunk; this should cut the lode at about 700 ft. An additional hydro-electric plant of 250 kw. capacity was completed in 1919, making this development possible. With regard to the future of the other two producers, I have no definite knowledge. The Syndicate mine has never been developed in depth, and is commonly reputed to have large reserves of rather low-grade ore, while it is generally conceded I believe, that the main orebody in the Colorado has been bottomed, and that the hope of a life beyond a few years lies in the possibility of finding and developing other bodies of pay-grade within the limits of the property. Be this as it may, there is sufficient ore in these mines to maintain production for some time to come, unless costs continue to climb to the point where profitable operation ceases.

The iron mines of Norway are chiefly in the extreme northern part of the country, in the Sydvaranger district. Owing to the fact that there is no coal the ore is concentrated and exported for smelting in other countries, chiefly England. In normal times the Sydvaranger mines employ about 1500 men; the annual production of ore is about 400,000 tons. Because of the impossibility of getting tonnage at any suitable rate for ore shipments, although the company had large contracts for freight made in 1914, transport of ore was largely stopped during the last three years of the War and the ore accumulated at the mines. The works were gradually shut down, and at the close of 1918 only about 500 men were employed. The re-opening of these mines is expected as soon as tonnage can again be obtained at suitable rates.

VIRGINIA is the only great producer of soapstone in the world, shipping more than 15,000 tons in 1918. The production has, however, declined irregularly for the last 10 years. Soapstone is one of the rocks that are most widely useful to primitive peoples, who, on account of its softness, resistance to sudden changes of temperature, and slow radiation of heat, employ it chiefly as 'potstone'—that is, for making pots. We make a similar use of it in soapstone stoves, foot warmers, and disks for fireless cookers, although in this country it is used principally in laundry tubs, laboratory tables, hoods, and sinks.

THE PANAMA CANAL OFFICE reports that traffic through the Canal in 1919 exceeded that of any previous year; 2396 ships of 7,128,000 net tons, in addition to naval ships displacing 1,000,000 tons, passed through the waterway. Cargoes of merchant ships amounted to 7,711,000 tons.

The Bunker Hill Enterprise VII

Development of Crushing and Concentrating Practice

By T. A. RICKARD

The first mill was built in Molo gulch, near the portal of the Reed tunnel, in 1886. The scheme of treatment is outlined in Fig. 1.* It will be noted that the equipment included Harz jigs and Cornish buddles. The capacity of the mill was 100 tons per day, from which it produced 20 tons of concentrate, containing 65% lead and 28 oz. silver per ton. This product was hauled to the narrow gauge railroad at Kellogg, which was then little more than a clearing in the dense forest that covered the valley. From there it was shipped to the smelter at East Helena, in Montana. Samples were sent from the smelter to the mine; the assays were made promptly at both ends, and the results returned by mail so as to cross in transit. It is curious to note that if the results did not differ by more than 2 oz. silver per ton and 2% lead, the difference was split and the settlement completed accordingly. Nowadays the margin for reasonable difference is reduced to half an ounce of silver and half of 1% of lead.

This first flow-sheet was elaborated in the next mill, which was built at the portal of the Kellogg adit in 1890. It was called the Old South plant and was supplied with ore by means of an aerial tramway that passed over the town of Wardner, as shown in one of the accompanying photographs. Fig. 2 gives the flow-sheet. The ore, after being crushed to 3-in. size at the mine, was delivered to a Bleichert tramway that discharged into a mill-bin holding 500 tons. When the Kellogg adit was completed in 1902, the present ore-crushing house was built and the use of the tramway was discontinued.

The sizing system consisted of a series of five trommels, made respectively of 36 mm., 18 mm., 10 mm., 7 mm., and 3 mm. round-hole screens. The successive products from these trommels passed to corresponding Harz jigs, each having compartments 19½ by 31½ inches. The undersize from the 3-mm. trommel went to four hydraulic classifiers. The first three spigots delivered to jigs of the same type as above-mentioned; the last two spigots delivered to two double-deck buddles of 16 ft. diameter. The overflow from the classifiers passed through a V-tank, 6 ft. deep and 90 ft. long, where it was thickened previous to treatment on twelve 4-ft. Erie vanners. The oversize from the 36-mm. trommel was crushed in rolls, 36 by 14 in. The middlings from the coarse jigs were ground in two pairs of rolls, one 30 by 14 in. and the

other 31 by 16 in. the product from these being delivered to a 16 in. bucket elevator that returned it to the head of the trommel system. The middlings from the fine jigs were ground in two 5 ft. Huntington mills and delivered from them to a 14 in. bucket elevator, which fed a 3 mm. screen the oversize from which was returned to the Huntington mill, while the undersize went to the head of the hydraulic classifiers.

The concentrate produced by the jigs assayed 58% lead and 25 oz. silver, that from the buddles and vanners assayed 45% lead and 20 oz. silver, whereas the tailing from the jigs assayed 3% lead and 1.2 oz. silver; and the fine tailing, 1.3% lead and 2.2 oz. silver. The average assay of the various concentrates was 55% lead and 24 oz. silver, at a total cost of 35c. per ton of crude ore. The ratio of concentration was 5½:1. These figures represent a general average of results between 1890 and 1906.

Tailing	129,683	2.37	1.59

This Old South mill was destroyed by dynamite during the great strike of 1899, of which I shall give details in a later article. The plant was re-built on the same site and on much the same plan in 1900. See Fig. 3. When the Kellogg adit was completed in 1902 the flow-sheet was changed somewhat, as shown in Fig. 4, which gives the treatment as it was at the beginning of 1906. In 1906 Gelasio Cactani started to remodel the mill and intro-

*This is based upon the recollection of S. S. Fowler, who was assayer and surveyor for the company, in 1888, and of Edward Hearing, who has worked in the Bunker Hill mills from the very beginning. He is now foreman of the company's plant at Kellogg.

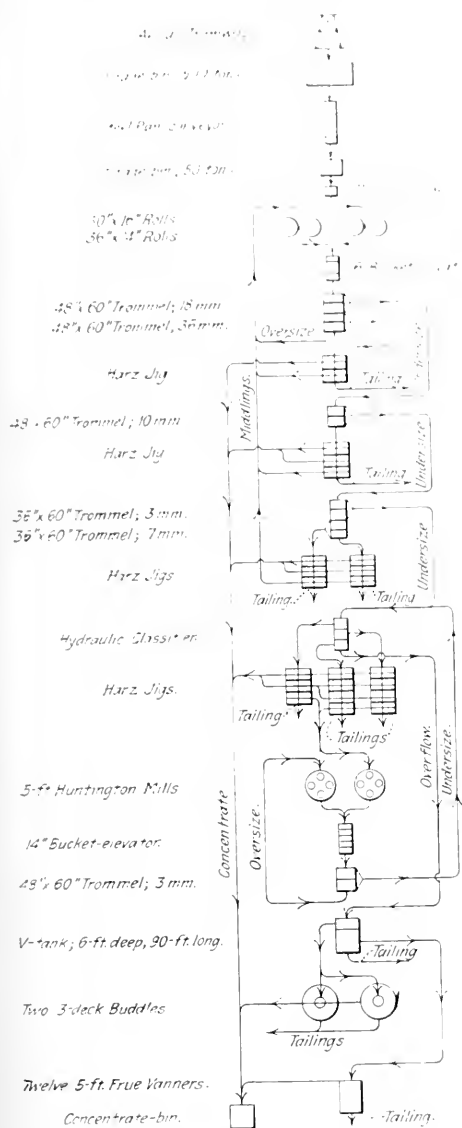

FIG. 3. FLOW-SHEET OF SOUTH MILL, 1900

duced the flow-sheet shown in Fig. 5. The principal change consisted in the addition of four No. 5 Wilfley tables and the discarding of the buddles. Two No. 5 Wilfleys supplanted the old buddles. The concentrate (40 tons per day, assaying 45% lead) from the coarse jigs was diverted to a 6-ft. Huntington mill and crushed to pass a 20-mesh screen before delivery to four No. 5 Wilfley tables. These made four products, as follows: (1) Slime, assaying 45% lead, which went to the shipping bin; (2) Middling, assaying 30%, which was pumped to

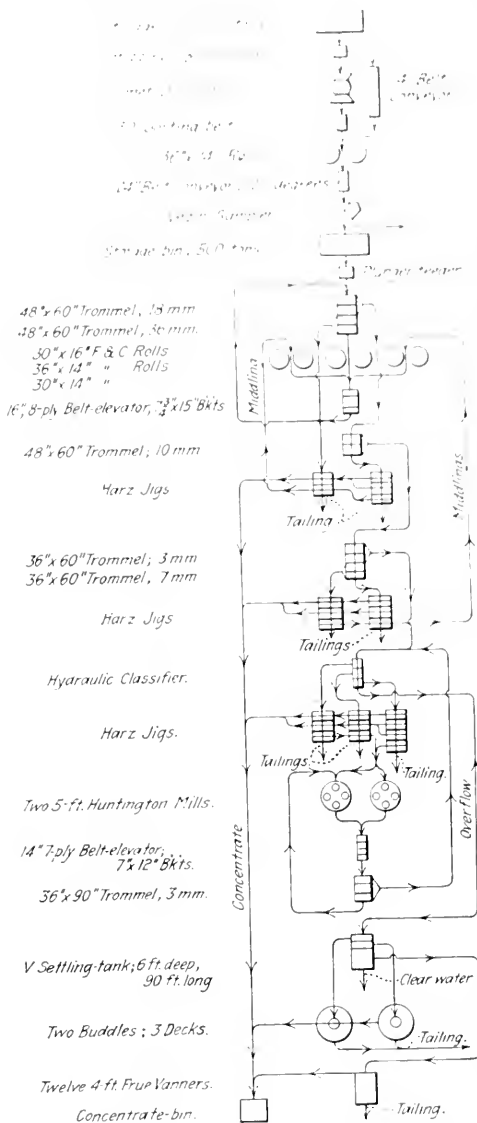

FIG. 4. FLOW-SHEET OF SOUTH MILL, 1906

a Wilfley sand-table; (3) Another middling, assaying 50%, which went to two grading Wilfleys; (4) Concentrate, assaying 77%, constituting the first-class shipping product. The Wilfley sand-table made a 45% slime, a 10% middling that was returned to the general mill-circuit, a 40% middling that went to the second-class bin, and a 70% concentrate that went to the two grading Wilfleys for re-concentration. These two machines received the products mentioned, together with the concentrates from the vanners and Wilfleys of the main plant.

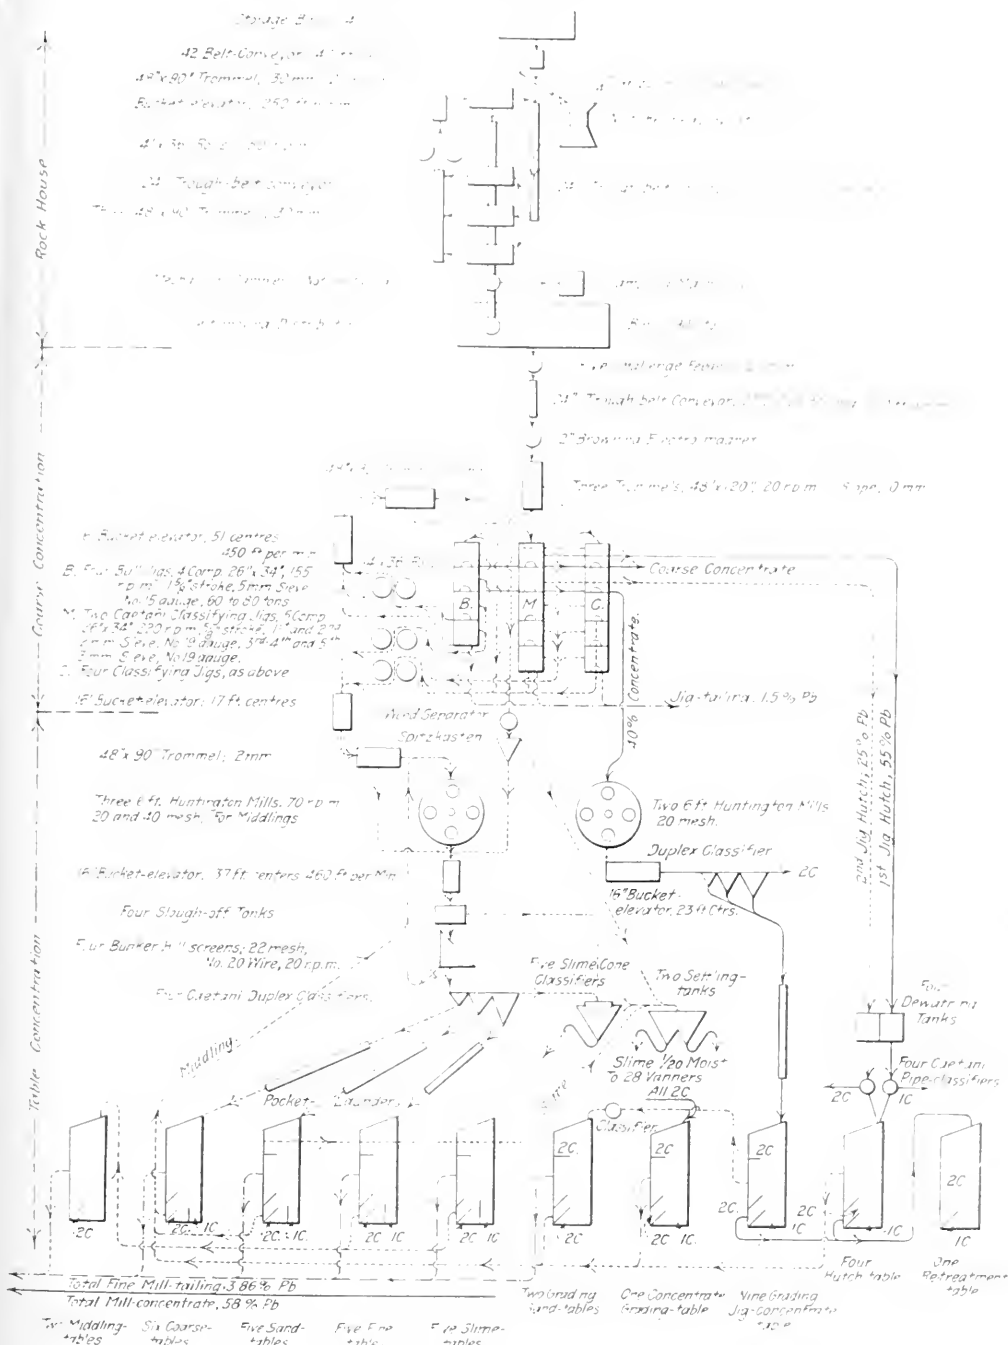

FIG. 6. FLOW-SHEET OF WEST MILL, 1909

NOTE. THE TROUGH-BELT CONVEYOR SHOULD BE 20 IN., NOT 24 INCHES

The products from these grading Wilfleys were a 50% slime that went to the shipping-bin, a 20% middling that was returned to the general mill-circuit, and a 77% concentrate that went to the first-class bin, for shipment. The total production of this high-grade (77%) concentrate was 12 tons daily. The object of producing such a rich product was to escape the severe penalty to which any product poorer than 75% was subjected by the terms of the contract with the American Smelting & Refining Co., and also to reduce the freight and treatment charges per unit of metallic lead in the concentrate.

It is interesting to note that at this time (1906) the Callow screen and the impact screen were tested in the grading process. The experience gained by Mr. Caetani in this mill, thus modified, was a decisive factor in designing the next mill, called the West No. 1, which started to work on November 9, 1909. During the intervening three years, experiments were continued in the Old South mill with a view to obtaining data for improvements in the new mill. During this period (1907-1909) the old mill was so crowded with ore that the recovery suffered considerably. A plant, known as the North mill, had been erected in 1907 to re-treat the tailing-dump of the Old South mill; therefore, when the latter became over-crowded, it was decided to use the tailing-plant of the North mill as an annex. The flow-sheet of this last-mentioned plant is shown in Fig. 5. To this annex came the undersize from the 3-mm. middling trommel, the middlings from the various fine jigs, the middlings from the Wilfley grading system, and the tailing from the vanners. These several products went through an elevator-house near the South mill and from there to the North mill, where they were sized on Callow screens, the oversize being ground by 6-ft. Huntington mills, and classified by hydraulic classifiers and Callow cones, previous to being treated on 24 No. 5 Wilfley tables and 16 Frue vanners. This treatment yielded 17 tons daily of a 43% product and 168 tons of tailing assaying $4\frac{1}{2}\%$ lead. Evidently a relatively rich tailing was going to waste, because it was profitable to treat more ore than the mill was capable normally of treating with the maximum metallurgical efficiency.

In January 1909 the South mill treated 27,400 tons of ore, assaying 14.2% lead and 5.1 oz. silver, the aggregate assay-value being \$15.48 per ton, with lead at 4.5 cents per pound and silver at 53c. per ounce.

Turning now to the flow-sheet (Fig. 6) of the No. 1 West mill, which represents the next advance in metallurgical practice, it will be noted that the run-of-mine ore was delivered to a storage-bin of 1400 tons capacity, and thence direct to a 42-in. flat-belt conveyor on a 10° incline to a grizzly having 14-in. openings. The oversize from the grizzlies went to a No. 5 Kennedy gyratory crusher, which discharged, together with the undersize from the grizzlies, onto a 24-in. Jeffrey trough-belt conveyor, delivering to three sets of trommels (each 48 in. diam. and 90 in. long) having 30-mm. apertures. The undersize from these trommels passed over a 24-in. inclined trough-belt conveyor feeding a self-propelling

Jeffrey distributor, to a storage-bin holding 1700 tons.

The oversize from the trommels was carried by another 24-in. trough-belt conveyor to a set of Chalmers & Williams rolls (36 by 14 in.), delivering to a 16-in. bucket-elevator, which took it to a trommel (48 in. diam. and 90 in. long) having 30-mm. apertures. The undersize from this trommel joined the material that had passed through the preceding trommels, while the oversize joined the feed to these trommels, in a closed circuit.

From the bin the ore, now reduced to 30 mm. or $1\frac{1}{4}$ in., was fed by five belt-driven Challenge feeders onto a 20-in. trough-belt conveyor, inclined at 22°, that passed under a 12-in. Browning electro-magnet and was then sampled by hand before going into three trommels (48 in. diam. by 120 in. long) having 10-mm. apertures. The oversize from these trommels was fed into four double jigs of the Harz type, each having four compartments, 34 by 26 inches. The undersize from the trommels went to four classifying jigs having five compartments of the same size as the preceding ones. These last jigs classified off, or separated, in the first compartment, a slime product of minus 20-mesh material. The first cup of the jigs yielded a coarse concentrate, assaying 53% and ready for shipment, while the second cup yielded a 40% concentrate, which was re-ground in two 6-ft. Huntington mills to pass 20-mesh before passing into the grading system, to be described later. The tailings from the jigs averaged 1.5%. The middlings from the coarse jigs passed through a set of Chalmers & Williams rolls (36 in. by 14 in.) delivering to a 16-in. bucket-elevator, which fed a trommel (48 in. diam. by 90 in. long) having 10-mm. apertures. The undersize from this trommel went to two classifying jigs, as before, while the oversize joined the middling from the fine jigs and was re-ground by two sets of rolls (36 by 14) delivering to a 16-in. bucket-elevator. This elevator discharged into a trommel (48 in. diam. by 90 in. long) having 2-mm. apertures. The oversize from the trommel was re-ground in three 6-ft. Huntington mills to minus 20-mesh, and then joined the undersize from the trommel, together with the spigot-discharge from a spitzkasten that treated the slime from the classifying jigs. There these mixed products were delivered by a 16-in. bucket-elevator to four spitzkasten, or 'slough-off tanks', the sand from which passed through four Bunker Hill screens of 22-mesh. The oversize from these screens was returned to the Huntington mills, while the undersize was prepared in four Caetani hydraulic classifiers for concentration upon six Card tables.

The overflow from the classifiers joined the overflow from the spitzkasten and was treated by a double-cone classifier. The sand from this classifier was discharged through a gooseneck to five Card tables, while the slime-overflow joined the overflow from the preceding spitzkasten treating the slime from the classifying jigs, this mixed overflow proceeding then to two V-shaped settling-tanks, which also received the backwater from 15 Card tables. The thickened discharge (1 part solid to 20 of water) from the settling-tanks was fed to twenty-eight 6-ft. Frue vanners.

The table-products consisted of a second-class concentrate that was passed over two Card middling tables to a bin and a first-class concentrate that likewise went to a bin, ready for shipment, while the middling was returned to a Huntington mill, and a 3.86% tailing went to waste. The various concentrates produced in this mill averaged 58% lead and 21 oz. silver.

To the foregoing general description it is necessary to add a note concerning the grading system for re-dressing the jig-concentrate. This product was re-ground in two 6-ft. Huntington mills to pass 20-mesh and then delivered by a 16-in. bucket-elevator to a duplex Cactani classifier. The overflow from this classifier was a finished second-class concentrate; the spigot-discharge passing

In discussing the relation between sizing and jugging, Mr. Cactani made the following interesting remarks:

"It may be said that the first action of a jig is to throw to the surface the lighter particles that cannot settle through its bed against the pulsating current of water. The heavy mineral will settle almost immediately; the middling will do so after a time, but the fine material, once rejected, will pass from one compartment to the other without being able to find its way into one of the products. The Wiltley table has a similar action on the slime, which, unable to settle between the riffles, is washed off by the head-water. On almost any concentrating machine there is some material that evades the action of the machine and becomes 'outcast'. The existence and

THE BUNKER HILL SCREEN

PIPE-CLASSIFIER

through pocket-classifying launders to nine Card tables, arranged according to the system previously established in the South mill. About 300 tons per month of first-class concentrate was produced by this grading system.

In 1910 Mr. Cactani published a series of articles† describing the milling practice as developed at that time. He gave an analysis of the ore, to which I have added later figures, supplied by R. S. Handy, his successor.

	1910	1920		1910	1920
Chemical	%	%	Mineralogical	%	%
Lead	13.58	10.3	Galena	15.70	11.80
Iron	22.85	18.0	Sphalerite	2.70	3.57
Zinc	1.80	2.4	Pyrite	3.15	1.57
Manganese	2.03	1.5	Siderite	44.30	35.80
Sulphur	3.80	3.6	Rhodochrosite	4.25	3.14
Lime		1.2	Calcite		3.30
Silica	23.90	40.0	Quartz	23.90	40.00
Oxygen		6.17	Silver	9 cz.	3.6 oz.
Carbonic acid	25.17	16.1			

character of this 'outcast' in the jig-tailings is illustrated in the following table, in which are compared equal-sized grains screened out of the tailings of five jigs of different sizes.

Size of grains	Size-limit of material fed to jigs					Slime
	mm.	mm.	mm.	mm.	mm.	
Through 3-mm. on 10-mesh	3.00	2.60	1.36	0.94	1.20	
Through 10 mesh, on 20-mesh	3.13	2.90	1.80	1.29	1.50	
Through 20 mesh, on 40-mesh	4.81	3.01	2.63	1.59	1.62	

"These figures prove that the fine sand remains 'outcast', especially on the coarser jigs.

"The character of an 'outcast' material will vary with the type of machine. On the bull jigs, even small pieces of ore will be thrown over the tail-board; and on fine

†'Milling of Lead-Silver Ore', in 'The Mining Magazine' for May, June, and July, 1910.

jigs, coarse pieces of ore will settle permanently on the sieve. Again, on a Wilfley table and on a vanner, oversize pieces of quartz will mingle with the concentrate." He concludes that the first effect of close sizing as applied to jigging, is the elimination of this 'outcast' material from the jigs, and that the limits between the sizes should be as large as will allow an easy separation, while keeping the bedding and the grade of the products in a stable condition. He proceeds: "This is especially true where the difference of specific gravity between minerals is small, as in lead-zinc ores, and where the ratio of concentration is high. Close sizing, however, is in many instances an accepted axiom, and a certain standard ratio of sizes is adopted without any theoretical or experimental guidance. As a consequence we find that sizing is often performed to an extent not justified by the character of the ore.

"These conditions are found in the South mill, where the screening is performed by five sets of trommels ranging in size from 36 to 3 mm. The trommels are overcrowded and their efficiency varies from 50 to 20%, that is, the products separated by the trommels contain 50 to 80% of undersize. Nevertheless, the jigs are doing remarkably clean work, because the Bunker Hill ore is well adapted for jigging.

"To determine these points an experimental plant of 100 tons daily capacity was erected, and it was found that with specially constructed jigs of the Harz type it is possible to handle all the mill-ore by dividing it into two products, a 30 to 10 mm. and a 10 mm. to zero feed. Until recently, it has been customary to jig coarser than 30 mm., but, since the lower levels of the mine have been opened, the galena is found to be more disseminated, and consequently the grade of the concentrate ranging in size from 30 to 36 mm. cannot be kept up to the grade commanding the best prices. The tailings from the coarsest jigs are remarkably clean; therefore, it is not the tailing loss, but the grade of the concentrate, that governs the upper size-limit of the ore to be jigged. The lower size-limit of the coarse-jig pulp is 10 mm. Sizing analyses show that the 10-mm. particles contained in the coarse-jig tailing are not higher grade than the same sized grains contained in the fine-jig tailing, nor are they appreciably higher grade than the total coarse-jig tailing itself; hence the 10-mm. particles are not 'outcast' when jigged together with the 30-mm. particles. The undersize of the 10-mm. trommel can be fed directly to the classifying jigs, which first separate the slime and fine sand, and then concentrate the desired portion of the pulp."

Speaking of the plungers in the jigs, he remarks:

"The length and speed of the plunger-stroke depend on the relative size of the plunger and jig-compartments, and on the size of the material treated. When jigging undersized material it is advisable to use a high speed and a short stroke. The fact that the smaller particles of ore occupy the interstitial spaces between the larger ones, gives to the water a greater lifting power on the coarse particles than it would have if acting on sized material. A long stroke on unsized pulp loosens the bed to

such an extent that the fine material is either sucked through the screen or thrown into disorder. [On the flow-sheet the stroke of the bull jigs is given as $1\frac{1}{2}$ in. and the speed 155 r.p.m., while for the middling jig the figures are $\frac{2}{3}$ in. and 220.] The plunger must have at least a $\frac{3}{16}$ -in. clearance all round, otherwise the suction through the sieve is too heavy. Plunger-valves have been tried, but without favorable results. The inconvenience of the air-blast caused by the movement of the plunger can be greatly reduced by boring two 2-in. holes through the partitions that divide one plunger-compartment from the other; the air will then circulate forth and back, and will not have the tendency to raise the plunger-lid."

In regard to the general principles underlying the methods of concentration, especially on the tables, Mr. Caetani remarks:

"1. In grinding, the free galena will concentrate exclusively in the fine stuff; therefore the oversize can be screened out and sent to the fine-grinding machines without first undergoing a process of concentration.

"2. No single machine should be required to do thoroughly clean work, but each operation of screening, classifying, or concentrating should be repeated by other machines on each single product of the first machine. Thus each machine acts as a roughing machine for the next following one, which in turn, treating material that is better prepared, performs a better class of work.

"3. Give each machine the greatest possible independence, by arranging that most of the pulps can be switched temporarily into other channels or onto other machines."

In regard to the Bunker Hill screen, he says that it is best adapted for screening from about 6-mesh to 80-mesh; for screening finer than 80-mesh, the Callow screen is preferable. Concerning the Card table, as compared with the Wilfley, he says that it has "a sharper return stroke with consequent greater progression and capacity, and increased simplicity in the method of suspending and adjusting the table. The Card also has the advantage of spreading the concentrate over a larger area, owing to the grooves, which, gradually becoming shallower, extend to the end of the table. . . The Card concentrator must have a fairly rich pulp to perform good work, that is, the ratio of concentrate to other products ought not to be less than 1:15, because this table, much more than the Wilfley, has to bed itself."

In closing his valuable paper, he says: "The chief aim was to design a mill of great mechanical simplicity and of high economical efficiency. Previous experience had taught that the main causes of troubles, delays, and repair-expenses are, in order of importance, trommels, bucket-elevators, transmissions, and liners. To prevent these troubles, the number of trommels has been reduced to a minimum, the wet elevators are made to elevate only comparatively fine material, the transmissions have been designed at the right angle, length, and direction, and placed so as to be free from grit and water, and special care has been taken to reduce the wear of the liners to a minimum. The mill is divided into three departments

mechanically independent, and the ore progresses from one department to the other, undergoing at each step a complete treatment, so that none of the products is ever returned through the channels and over the machines through which it has already passed. This prevents the idle circulation of products; they move rapidly through the course of treatment, with the result that the mill is very sensitive, any change in one part of the mill being immediately shown in other parts. This sensitiveness calls for more attention from those in charge, but prevents any defective operation remaining undetected and is, I believe, a most valuable feature. All the products of

was 141 tons of middling assaying 16.9% lead and 5.8 oz. silver, worth together \$8.54 per ton, or a total of \$946. Thus the total mill products weighed 3250 tons, assaying 30.8% lead and 18.4 oz. silver, worth together \$30.90 per ton, or \$100,499 in all.

Operations in the Old South mill were discontinued in 1912, when the second unit of the West mill, called No. 2 West, went into operation. Thus No. 2 West mill was started on April 17, 1912. It occupied part of the building in which the No. 1 plant was housed and was intended originally as a duplicate. This fact restricted the mechanical arrangements, particularly the sizing system. A description of the plant has been published by R. S. Handy, the mill superintendent, and I take pleasure in quoting from his article.¹

The flow sheet is shown in Fig. 7. It will be seen, as Mr. Handy says, that "there is a gradual reduction in the size of the particles of middlings by means of rolls as far as they are efficient, and, finally, by fine-grinding machines. At each step the freed galena is taken off and the tailings produced by cracking the particles are disposed of before the material is again subjected to reduction. While this complicates the process and makes a large tonnage of middling to be re-handled, it does not result in an excess of slime, as the material is extremely hard. The middlings are not mixed with the original feed until it enters the slime department, and the jigs on the original feed have a uniform load, and are kept up to a high standard of efficiency. Another object striven for is to keep the amount of circulating water as low as possible. To do this, the gradients of the launders have been made ample to carry the products with a minimum of water. The fine trommels are washed with pipe-sprays. The thin streams from these impinge on the ore as it rolls in the trommels and, having a constant head, deliver a constant volume of water into the system. The feed to the rolls and grinding machines is first de-watered, and the wash-water necessary to carry the discharge is applied through spigots with constant heads from the dewatering boxes. The total water recovered from the slime amounts to 372 gallons per minute when treating 550 to 600 tons of mill-feed."

Among the minor features of the milling practice in 1912, Mr. Handy mentions the use of roll-shells made of manganese-steel, trued with carborundum bricks; trommel-feeders for the rolls; the drilling of holes in the bottom of buckets on the fine-elevator to destroy suction; the use of washers made of pure rubber between the buckets and the belt of the elevators, in order to pass the fine sand instead of allowing it to lodge and wear the belt; the air-lift for returning the overflow-water from the bins, etc., for wash-water on the tables; and the complete equipment of all bearings with Keystone grease-cups provided with loose copper pins to automatically feed the grease to the bearing as required; and the use of double-edged or overflow-boxes on the thickening-tanks.

(To be continued)

SKETCH OF PIPE-CLASSIFIER

one machine are generally re-treated on other machines, the function of which is to rectify the work performed by the first one. By this arrangement any faulty operation that has taken place in one part of the mill is detected and corrected in other parts. The only two products excepted are the extreme ones, that is, the highest grade concentrate and the tailing, and these are kept within a large margin of safety."

In July 1911 the South mill treated 20,500 tons, assaying 9.95% lead and 4.2 oz. silver, the combined value being \$11.17 per ton. The products were 318 tons of first-class concentrate from the jigs and 312 tons from the Wilfley tables, the combined tonnage of first-class product being 630, assaying 77% lead and 26.4 oz. silver, worth together \$57.16 per ton, making \$36,011. The second class product included 1266 tons of second and 375 tons of third classes of concentrate as well as 867 tons of slime, the total being 2508 tons, assaying 45.7% lead and 16.5 oz. silver, making \$25.30 per ton, or \$63,452 in all. There

Herbert Hoover: A Sketch

By T. A. RICKARD

Herbert Clark Hoover was born in the town of West Branch, Iowa, not quite 46 years ago, of Quaker stock. He is the son, grandson, and great-grandson of Western pioneers. His father, Jesse Clark Hoover, was a blacksmith and machinist. An orphan at ten, he went to live with an uncle in Oregon. At the age of 14 he went to work in a real-estate office at Salem, and prepared himself for college by studying at night. In 1891, when 17 years old, he entered with the 'pioneer' class of Stanford University, which had just been opened. He worked his way through college by assisting John C. Branner, the professor of geology and later the president of the University; he made a little money also by means of minor business enterprises, including the agency for a laundry. He helped his brother, who likewise entered Stanford; indeed, they helped each other; he also aided a girl cousin to an education. He has always been of the helping kind. At college he was a hard-working, serious, diffident fellow, but co-operative, a leader and an organizer. He used to walk down the campus with his hands in his pockets and his head bent in thought—as he does now. He had no use for fraternities, he was a 'barbarian'; nevertheless he was elected treasurer for the student-body, whose athletic affairs were much in need of financial organization. He placed them on a businesslike basis and performed his duties so well that he won general approval and respect. He has managed bigger affairs since then with the same thoroughness and sincerity.

He had decided already to be a mining engineer; the idea had appealed to his imagination even before he went to Palo Alto, largely owing to a chance encounter with a mining engineer whom he met while in Oregon. During intervals of college life he had served on the staff of the State Geological Survey of Arkansas, under Dr. Branner, and of the U. S. Geological Survey in California, under Waldemar Lindgren. After graduating, in 1895, he went back to Dr. Lindgren, at Grass Valley, California, and remained with him until that season's work was done. Then he got a job in the Reward mine in the same district and later that year he worked in the Mayflower mine, at Nevada City, which is close to Grass Valley. Eager to learn more, and acting on a suggestion from his friend George Hoffmann, he decided to try for an engagement with Louis Janin, one of the leading mining engineers of the country. That was in December 1895. Janin gave him a desk in his office in San Francisco and found work for him to do; he surveyed the Carlisle gold mine in New Mexico and helped in the examination of the Four-Mile placers in northern Colorado, besides other work of increasing responsibility. He made good. These activities occupied the year 1896. When Janin received a cablegram asking him to send a capable young engineer

to Western Australia, he named Hoover. That was in February 1897.

In Western Australia he became engineer on the staff of Bewick, Moreing & Co., who were managers of a large group of important mines. He was put in charge of two or three of them in succession, organizing their operations so as to decrease the cost of production and establish them on a more profitable basis. He had changed but little; he was the same quiet, rather shy, persistently busy young man. It needed no unusual insight to detect his keen intelligence, power of quick decision, and, above everything, the ability to distinguish the essential from the non-essential factors in any given problem. He was both a good appraiser of mines and a capable manager of them.

Late in 1898, when only 24, he was offered the position of chief engineer to the Chinese Imperial Bureau of Mines. He went to Peking and commenced a series of explorations in the interior of China. In 1900 he happened to be in Tientsin during the Boxer uprising and took part in the defence of that city. In 1901 he became general manager for the Chinese Engineering & Mining Co., in which Bewick, Moreing & Co. were interested. A year later he became a partner in the firm and went to London.

In January 1903, soon after he joined this firm, one of the partners, an accountant named A. S. Rowe, misappropriated \$700,000, belonging to sundry West Australian mining companies. In the absence of the senior partner, C. Algernon Moreing, and without legal obligation to do so, Mr. Hoover committed his firm promptly to the re-payment of the missing funds.

He remained with this engineering firm until 1908, and during these six years he examined and directed mines in remote parts of the earth, gaining wealth and reputation. Even when he retired from the firm and opened an office of his own he was only 34 years of age; by that time he had won a commanding position in the mining world. He was elected director of several important companies in Australia, Siberia, and Burma. Early in 1914, just before the War, a group of mining companies got into trouble through the irregularities of their chairman, who went into bankruptcy. The mines affected by the fiasco were the Camp Bird in Colorado, the Santa Gertrudis in Mexico, and the Messina in the Transvaal. In order to allay public anxiety it became necessary to select a man who could command general confidence. Mr. Hoover was selected. He became chairman and continued in that office until 1916, when he resigned all his directorships in order to give the whole of his time to the great tasks to which the exigencies of war and his public spirit had drawn him. Before leaving this

last episode in his mining career, it is proper to lay emphasis upon the selection of Mr. Hoover to restore public confidence in a group of embarrassed mining companies. He owed the honor to force of character, not to any amiability, subservience, or snobishness. In London he could not be mistaken for anything but an American, and a Western man at that; he was uncompromisingly, even bluntly, American. He won the esteem and the personal confidence of the foreigners with whom he came in contact, but his closest friends continued to be Americans, and he never had any other idea than to re-

veal hundred Latin books to answer his needs. These had stumped all Mr. Hoover's predecessors. He set to work in characteristic fashion. First he collected other books by Agricola and his contemporaries, and, by comparing contexts, discovered the meaning of the doubtful terms. Not a classical scholar himself, he succeeded in his task by utilizing the services of professional translators and then applying what medieval Latin he had acquired, by his study of the literature of the period, to their renderings. Mrs. Hoover and his brother, Theodore J. Hoover, aided him. His spare time for three years was devoted to

MR. HOOVER AT WORK

turn home as soon as his children were old enough to go to school. Since 1910 he has had an office as mining engineer in the Mills building, San Francisco.

Mention must be made of his contributions to technical literature. His first article appeared in the 'Mining and Scientific Press' of February 29, 1896. The subject was 'Vein-Crossings'. In 1908 he delivered a series of lectures on mining at the universities of Stanford and Columbia, these lectures being cast later into book form and appearing under the title of 'Principles of Mining', in 1909. His literary achievement was the translation of Agricola's 'De Re Metallica', a Latin treatise printed in 1556. The translation, issued in 1912, is a folio of 640 pages, of the same size as the original and bound in vellum. Others had tried to translate this classic volume, but they had failed, chiefly because Agricola coined sev-

this task. The notes he added to the translation by themselves constitute a valuable volume. The publication was done with no idea of profit, the cost of the book being three times the selling-price. It was a remarkable example of initiative, method, and persistence. The Mining and Metallurgical Society of America bestowed its gold medal on Mr. and Mrs. Hoover for this performance.

When the War broke out, in August 1914, there was a big rush of American refugees to London, on their way homeward. Thousands of them were stranded and in trouble. Mr. Hoover and a number of other American mining engineers organized a committee to help their countrymen in distress. Mr. Hoover was the chairman of that committee. The Americans had no sooner effected a clearance than the Belgians began to arrive. The story of their sufferings and of the pitiable plight of their

country went to Hoover's heart; he started measures of relief, at first in a small way, then on a colossal scale, buying shiploads of foodstuffs. This was started the celebrated "C. R. B.", the Commission for Relief in Belgium. He met with opposition, for he was ever informal in his ways, but when his purpose was understood and appreciated, he received support and money from the British government and grudging recognition from the German officials in Belgium. One of the first things he did, after appealing for subscriptions to the C. R. B., and, was to have the books of the Commission audited monthly by the leading firm of accountants in London. He put his benefaction on a sound business basis immediately. During the perplexing period before the United States entered the War he had countless difficulties, diplomatic and otherwise, to overcome. He traveled continually from London to Brussels, from there to Berlin and Paris, in his earnest effort to prevent anything from stopping the feeding of the seven millions of unhappy Belgians, on whom the heel of Germany was pressing so hard.

As soon as the United States declared war, he was called by President Wilson to serve as head of the Food Administration. Again he proved his capacity to the hilt, evoking a cheerful response from the American people when they were told to save food, or 'hooverize'. The women of the country, more particularly, rallied to his support. His administration of our food resources is one of the few cheerful features of the management of national affairs during the War. When suddenly the Armistice ended that splendid work, as our declaration of war had ended his work in Belgium, he turned to the greatest of all his undertakings. As head of the American Relief Commission he became economic dictator of more than half Europe. Congress gave him \$100,000,000 to spend; he used it seven times over, feeding the famishing peoples of Europe, and received securities from European governments equivalent to 90% of the fund. The Relief Commission is still feeding 2,500,000 children. When peace was formally concluded at Paris, he came home and prepared his report to Congress. In November 1919 the President appointed him vice-chairman of the Industrial Conference, now in session at Washington, a task to which he is devoting himself earnestly, serving as presiding officer. Last October he was nominated for the presidency of the American Institute of Mining and Metallurgical Engineers, and on February 16, 1920, he was elected. On February 18 he received the medal of the Civic Forum of New York in recognition of his "distinguished public service". Herbert Hoover is the greatest of living Americans; he is the most useful man in the world today.

During the past year 8400 men were employed in the mines and quarries of the Province of Quebec. These men have worked for a total number of days represented by 7077 men working a full year of 300 days. Accidents to 446 men, of whom 12 died of injuries sustained, have been reported during 1919. In the previous year, with

6350 men employed, 224 accidents were recorded out of which 29 were fatal. Due to higher wages and to a greater number of men employed in the mining industries an increase in the total of the salaries paid is recorded. During the year 1919 the total sum paid amounts to \$7,312,764, as compared with \$6,149,448 for 1918.

Coal Production of India

The known deposits of coal in British India are limited and the quality is comparatively poor. The annual output has now been raised by some 20,000,000 tons, and it is stated the industry pays handsomely. India, however, is surrounded by countries that could take a great deal of this coal if it could be spared. Indian industries again are but in their infancy and are using practically all the coal mined. There are in addition the railways and the iron and steel industries.

The two iron and steel companies are expanding their business in a most remarkable manner, while a third company, soon to be operating in Bengal, promises also to expand into a great concern. The Bengal Iron & Steel Co. is now producing 120,000 tons of pig-iron per annum and is contemplating large extensions, as is natural in view of its possession of a practically inexhaustible supply of high-grade ore with an iron content of 60 to 66%. The Tata Iron & Steel Co. is similarly circumstanced as regards ore; it has in the 12 years of its existence already left far behind its original program of production, having begun with the modest idea of turning out 120,000 tons of pig-iron annually, whereas its production has already reached twice that figure. It has a present capacity, besides, of producing 17,000 tons of steel per month. Its rolling-mills have capacity for an annual output of 120,000 tons of rails and smaller sections, and it soon expects to be in a position to use up to 1,250,000 tons of coal annually for conversion into coke. This, too, is only a beginning, for, whereas recently the company employed 13,000 men, with another 10,000 at work on extensions, it is contemplating the early layout of an industrial town to accommodate 50,000 persons.

When in addition to the demands on coal by these two works there come into existence the works of the new Indian Iron & Steel Co., a very large amount of good coking coal will be required—and this class of coal is by no means too plentiful in India. The result may be that the price of coal will rise to a higher figure. Then there are other minerals which, the Geological Department states, exist in abundance, and which it is proposed to mine and put to use—manganese, aluminum, lead, tin, copper, and tungsten. When these contribute to the industries of the country further demands will be made on the coal output. But apart from the industries it is certain that general trade will grow enormously in the near future and with it will come an increased demand for coal. The Indian coal situation consequently deserves serious consideration. The immediate development of hydro-electric resources would take some of the burden off the coal mines.

The Contract Wage System for Miners

By A. K. KNICKERBOCKER

***PRESENT METHOD OF PAYMENT.** Practically all underground work on the Minnesota iron ranges is done by miners working on a so-called contract wage system. This system, while it has certain advantages over the straight day's-pay or company-account method of wage-payment, has serious and vital defects. In view of the scarcity and demands of labor, it is important that employers of labor scrutinize their systems of wage-payments carefully, not only to save losses and trouble, due to labor disturbances, but also to secure the greatest efficiency of their workmen and reduce their operating costs. It is admitted that an adequate, just, and equitable wage is the prime factor in bringing about these benefits.

The wage of labor and its method of application and payment have been, and always will be, the main factors in the unrest and dissatisfaction of labor. Not only does labor want and need an adequate wage, assuming that work is adequately performed, but it wants and is entitled to a just and equitable wage. Labor must have respect for the fairness of the wage and for the fairness of the management in the application of the wage. It is conceded that the Minnesota iron miners are now, and have been, in the main paid adequately, but the inherent defects of the so-called contract system prevent any just or equitable application of this wage to individuals.

The defects of the contract system, with its obvious inequalities, favoritisms, and injustices, are cancers in the brain of those that labor. Every thinking miner realizes these defects and knows just what they are; the unthinking do not realize the details of the subject, but each month they are forcibly reminded of these defects through the pay-envelope. As practised on the iron-ranges, however, the so-called 'contract' system is not a contract and the name is a misnomer. No true contractual obligation exists.

As usually practised, the contract system involves the setting of a price per foot in development work, or per foot or per car, usually the latter, in slicing or stoping, by the mining captain, and assumes its acceptance, though oftentimes under protest, by the men. A price is set for each working place, in which there are usually two men per shift. This price includes labor and supplies, such as explosives, fuse and caps, shovels, and carbide, and the men divide the total earnings less the amount expended for supplies. The cost of the supplies charged to the men varies in different mines; in some cases supplies are furnished free. In general, the companies furnish machine-drills, hose, steel, picks, rails, cars, timbers, boards, lagging, perform some of the transportation and

all of the hoisting, and may do some of the track work. The miners do all of the shoveling, drilling, blasting, and timbering, and some of the transportation. Supplies chargeable to the men are usually furnished at cost, plus 10% for handling.

In general the rate per foot or per car, or the contract price, is set at the first of each month to govern that month. Earnings are frequently calculated and checked by the mining captain; and many companies also figure the rates on the fifteenth of each month. Some of the contracts will show large earnings, others average earnings, and others small earnings. When the earnings are small, the rate has been insufficient, in which case it is raised, and a new rate governs the remainder of the month; or the contractors have encountered unusual and unexpected difficulties, in which case the contract may be closed and the men paid off at the company-account rate and a new contract started, or they are allowed footage or cars not actually earned; or it is concluded that the men are poor workers or unskilled miners, in which case they are paid off at the company-account rate and discharged, new men are hired, and a new contract started.

DIFFICULTIES OF APPLYING CONTRACT WAGE SYSTEM. The difficulties of the system arise from:

1. The setting of the price, often under protest from the men, by one individual, the mining captain. This price is set to the best of his ability and is based on his mining experience, his knowledge of the men and of the ground, and his opinion of the probable conditions that will present themselves through the month. It is impossible for one individual to set prices equitable throughout the mine. Hard or soft ground, heavy conditions or the reverse, and other difficulties, due entirely to the nature of the work, may be encountered so that the price set by the mining captain is a mere guess.

The human-nature problem enters also, oftentimes unconsciously. For instance, if two gangs of miners, one composed of good men and the other of extra good men, are working under exactly similar conditions, the captain will be tempted to give a slightly lower price per car to the better gang to prevent its 'running away' or securing an abnormally high wage, thus penalizing the better gang or subsidizing the poorer. The captain excuses this practice, to himself and the miners, by fancying some difference in conditions in the two places. Where he is unable to so fancy a difference, he must pay the same rate in both cases; but in that case the rate will be reduced, thereby reducing the earnings of both contracts simply that one shall not make an abnormally high rate.

Furthermore, favoritism develops as another result of the human-nature element. Certain favored, though no

*A paper presented at the New York meeting of the A. I. M. & M. E., February 1920.

doubt hard-working and efficient, miners will receive the best places and get the highest wages month after month. The rule of seniority is not often practised, and is as often overlooked as not.

2. The difficulty in foreseeing, 30 days in advance, what conditions underground will be, and the multiplicity of operations entering into the contract price make the off hand setting of this price by the captain a mere guessing matter. The ground may change; it may get heavy, be soft or hard and vary within short distances; water may increase; poor timber or heavy ground may necessitate extra timbering; no two tramping distances are exactly alike; the ore may be heavy or sticky or vice versa; and numerous other factors enter to influence earnings. Do all these factors influence the price, each in its proper proportion? They surely do not; but they should, if the miner is to receive pay for work performed. That they do not is no reflection upon the mining captain; he does the best he can, and nobody attempting to make contracts in this guesswork fashion could do any better.

3. Certain other difficulties, by no means unimportant, arise from the nature of the piece-work system itself, and are common to the system as applied in any industry. In many manufacturing plants, the operations of which are standardized and are performed in a routine manner day by day, the same objections apply. The principal disagreeable factor is rate-cutting, after a rate has been set and earnings have been found to be abnormally high. In mining, it works somewhat as follows, assuming that a certain 'gang' has started a new place and that the rate has been set by the captain: The rate will represent his best judgment of what the gang will produce as against his idea of the wage he would like to pay them. This rate may not necessarily coincide with the miners' conception of a fair rate. They are often as experienced and possessed of as good judgment in this matter as the captain. The captain's mere assumption that they will be able to make normal earnings is not necessarily conclusive to them and what they think of the situation, not what the captain thinks, will most probably govern their actions.

After the captain has set the rate, one of three things is bound to happen:

1. The miners consider the rate satisfactory and go ahead and do a good month's work, then

(a) If the rate happens to be satisfactory, they receive a good month's pay and everybody is satisfied. The company has received good production and the miners have had proper pay; this is the ideal condition.

b. If the rate happens to be high, the miners will make an abnormal wage. This is a frequent occurrence and has a pernicious effect; here, the company loses money on the men. In the first place, the miners who have done a good month's work but who have received an average or below an average pay, do not consider the receipt by this gang of an abnormal wage as at all just; therefore a certain proportion of the force is immediately dissatisfied, with the usual results of demands for higher rates and the uncalculated quitting of men. Also, as a rule, the rate of the high-wage gang is cut for the suc-

ceeding month with the result that these men are dissatisfied and quit or work in a half-hearted fashion.

(c) If the rate happens to be low, the miners will make a low wage. Here, the company makes money on its men, if it looks no farther than the earnings of the men and the tons of ore produced by them. In reality, it is as much of a losing proposition for the company as either of the others. The men consider that they have worked as hard through the month as any of the other men, so the result is a dissatisfied gang.

2. The miners consider the rate too high, regardless of whether it is or not, and so will not do their best work. They think that to do so will mean that their earnings will prove abnormal and thus lead to rate-cutting at the end of the month. They, therefore, fail to produce a normal output until such time as the captain discovers their attitude and attempts to remedy by either discharging men or setting a new and lower rate.

3. The miners consider the rate too low and either quit or do not give a full measure of work. The less work they do, provided they are not discharged, and to some extent even if they are, makes it more certain that sooner or later the captain will raise the rate. Miners cannot be forced to work, and the captain must avoid low production. If his gangs refuse to work and give him production, he has two remedies. He can discharge the men or he can stimulate them by raising the rates. What he will do in any instance depends on how widely the dissatisfaction is spread through the mine and on the character and supply of miners available.

On the Minnesota ranges, conditions if one mine are not radically different from those in others, yet there is a constant migration of men from mine to mine—an economic loss to both the workers and the employers. Not only is the system economically poor in its effects on labor and on the employing companies, but the influences of the injustices of the system on the mind of the worker make him a fruitful field for the agitator. The system is a constant trouble-breeder and mischief-maker. It allows a continual heckling and disturbing of labor and it will continue to be the prime factor in labor unrest.

SUGGESTED IMPROVEMENTS IN CONTRACT SYSTEM. As a matter of fact, the average miner does not want the system abolished. He prefers it over the day's-pay system, for it allows him to earn by the expenditure of effort, a wage greater than the company-account wage. He knows that to go back to the day's-pay system would cause, in effect, a general reduction in the level of wages. What the miner wants is a contract system based on something more tangible than the autoeratic judgment of one individual.

The keynote of the improved plant is standardization, based upon accurate and sympathetically carried out time-studies. No piece-work wage-payments can be made satisfactorily unless each operation is standardized and the time and cost of doing it are definitely known. In other words, we must have, instead of rates set upon individual autoeratic judgment, rates determined scientifically and based upon long-continued and accurate

time-studies made by competent and experienced engineers who understand underground conditions.

The business of mining iron ore is not simple, and to handle the matter we will have to divide it into simple operations capable of definite time and cost ascertainment, and classify these operations into two classes—fixed operations and variable operations. The fixed operations are: Shoveling, drilling and blasting, tranning, timbering, boarding-up and blasting-down rooms, and track-laying. These are all fixed determinable factors that, by means of accurate and long-continued time-studies, based upon the work of average miners, would give a determination of the proper pay. These time investigations would prove, for instance, that the average miner can shovel ore to fill a car of certain size for X cents, which amount should then be the price paid for this work all through the mine, until such time as the general level of wages is changed.

Likewise with drilling and blasting; although experience would point the way to the proper method of handling this question. Whether this work should be paid for at so much per car, per ton, or per foot of hole drilled, is a matter that could be worked out at the proper time. This item is also a semi-variable, in that the several kinds of ground must be considered. To handle this successfully, the number of kinds must be kept at a minimum. Five grades are suggested, very soft, soft, medium, hard, and very hard. This is the only item where the judgment of the mining captain is brought into play, or the only chance there is for any disagreement or argument between the men and the captain. Surely the captain should be able to classify any face into one or the other of these five grades, especially as the grades will have been well delineated by the preliminary time-study and investigation work. The system should be worked so that the rate on this item can be changed during the month as often and as quickly as the ground changes from one class to the other.

Similarly, tranning should be paid for at so many cents per car of various sizes tranned 100 ft. or fraction thereof. Timbering would be paid for at so many cents per set. The rate would raise or lower with a change in the length of post or cap or both, above or below base lengths. Boarding-up rooms would be paid for at so many cents per hundred square feet boarded, and blasting-down of rooms would be paid for per 1000 cu. ft. of room blasted-down. Tracklaying would be paid for at so many cents per linear foot for straight track, so many cents per foot for curved track, a lump sum for switches, frogs, and tracks into slices. Since in most mines a good share of the track-work is done by a special track-man this item would not be very important.

The variables entering into the problem are, unhappily, numerous, but the crux of the whole problem lies in the treatment of these variables. The variables include all those items that cause a loss of time to the miner and prevent him from using his time in one or the other of the above six fixed operations. These delays should be classified into two well-defined classes: those for which

the miner is responsible and which could have been avoided by ordinary skill or foresight on his part, and those that are in no way under his control and are due to neglect of the company or accidents due to the nature of the work, such as unforeseen caves or falls of ground. For the first class, the miner should receive no pay. For the second, he should automatically go upon company-account pay the minute that he starts to suffer delay and be paid for all the time he is so delayed. This company-account rate should be made low so that advantage will not be taken of it, and also because there is presumably little or no expenditure of effort in most of the cases coming under this classification.

The contract sheet at the end of the month would then look something like this:

To shoveling A cars, A size, at a cents per car,	
To tranning B cars, B size, 300 ft., at b cents per car per 100 ft.	
To drilling and blasting, soft ground, at d cents per car (or foot of drift)	
To timbering, E sets, 7-ft. post, 6-ft. cap, at c cents per set	
To boarding-up rooms, F sq. ft. at f cents per 1000 sq. ft.	
To blasting-down rooms, G cu. ft. at g cents per 1000 cu. ft.	
To H hours delay, waiting for full chute, at x cents per hour	
To I hours delay, blasted-down sets, no pay.	
To J hours delay, no air, at x cents per hour,	
To putting in K props, at k cents per prop.	

Supplies could be handled in the usual way and be included in the standard rates, or supply standards could be adopted, supplies furnished free, and savings made by efficiency on the part of the men divided between the company and the men, on an equitable basis.

The plan as outlined is still a straight piece-work system. Whether it would be advisable to develop a standard day's work and standard day's pay and encourage efficiency by the installation of some sort of bonus payments is a matter that would develop as the system was worked out and put into practice. The introduction of bonus-payments would be a complication to avoid until such time as the improved piece-work method has received a good trial, become stabilized, and found favor. It is believed, however, that a bonus for attendance, or the granting of a shift or half-shift per month for full or nearly full attendance during the month, would help to keep the working force full each day and is an application of the bonus system that might be instituted immediately upon the adoption of the improved piece-work system.

A little more clerical work would permit of the calculation of the earnings of each contract each day, with a daily posting of earnings in the change-house, where they could be observed by the men. As a stimulation to a man to put forth increased efforts, there is nothing like knowing what his present efforts are actually bringing him

and an immediate knowledge of his earnings each day. Whether such a step is advisable or will pay for itself is open to experiment after the system is in proper working order.

DISADVANTAGE OF PROPOSED SYSTEM. The disadvantages of the suggested system are, of course, items of cost, due to the extra supervision and time-keeping, and the necessity for frequent check-ups by the management. In a small mine, the details could be looked after by the shift-boss, but a mine of any size would require men doing nothing else but checking time and looking after the operation of the system. It is believed that the extra labor would earn its money, as the operation of the system would be, in effect, a continuation of the preliminary time and cost studies, and it is felt that the system would present facts of operation in such a manner as to quickly uncover the weak spots of an operation and suggest means for the application of suitable remedies. For instance, the daily records would show that some gangs were above the average in certain lines of work and below the average in others; steps could then be taken to discover the gang's difficulties and by education improve the production and earnings of the gang and lessen the cost to the company. Certainly it would mean a detailed and accurate cost system applied where it should be applied, to the man actually producing the ore, and it is inconceivable that the system would not furnish to the captains and superintendents a ready and up-to-date means of detecting weak spots in their operations and determining quickly and accurately the means of correcting them, and thus lead to a general reduction of costs.

Another disadvantage is that the system could not be put into operation without some initial and preliminary time-studies and investigations performed on average men and under widely varying, though typical, conditions, and under supervision of men sympathetic to improvements. The longer this work is continued prior to the adoption of the system, the more accurate and fool-proof it will be. These investigations can best be made by the large companies, having various mines and with large organizations equipped for the work. The cost would be prohibitive to a small company. This preliminary investigation would no doubt take two or three years' time and cost some thousands of dollars, but the savings made on the millions of tons of ore mined and shipped each year would repay the cost many times over, as a result of the knowledge obtained, even should the work stop with the preliminary investigations.

ADVANTAGES OF PROPOSED SYSTEM. The advantages are numerous and have previously been indicated, but for convenience will be here summarized briefly: (1) Prevention of disputes; the basic rates for each operation would be standard throughout the district. (2) Less dissatisfaction among the men. (3) Less opportunity for the strike-agitator. (4) Better work by the men, due to the fact that they would see that unfairness and injustice had been abolished and would feel that they were getting paid fairly for work performed. (5) A smaller labor turnover. (6) A reduction of operating costs to the

companies. (7) Opportunity for increasing the efficiency of the men and the improvement of operating conditions and methods, due to detailed costs presented quickly and the knowledge obtained from them.

The suggested system may not be the best, and it is not expected that any fair system can be derived without actual study and experimental trial, but in the interests of both the men and their employers, some steps should be taken to improve the present system.

MANGANESE deposits have been known in Panama for many years, and some were extensively worked as early as 1871. None was recorded in Costa Rica, however, until 1915, when American engineers found deposits in western Costa Rica and, under the stimulus of the prevailing high prices, explored many of them. During 1916, 1917, and 1918 about 18,000 tons of ore was exported from Costa Rica to the United States. In October 1918, the U. S. Geological Survey, taking advantage of the presence in Costa Rica of an American geologist, J. D. Sears, had the deposits examined. Dr. Sears afterward visited several new deposits in Panama. The deposits in Costa Rica are found at several places on the Nicoya peninsula, in the Province of Guanacaste, which extends along the Pacific Coast. Most of the known deposits, and all those which have been the source of the shipments, lie within about 16 miles of Playa Real on the Pacific Coast in the northern part of the peninsula. Although deposits of manganese oxides were examined at 36 places near Playa Real, most of the ore shipped has been derived from three deposits that lie in an area scarcely 1000 ft. square at Playa Real. These deposits are owned by the Costa Rica Manganese & Mining Co., an American company. At Playa Real, as at many other places in the region, the manganese oxides form very irregular masses, which appear to extend along the crests of hills. The genesis of the deposits is obscure, but sufficient work has been done to show that only a few persist for as much as 100 ft. below the surface. Estimates of the size of the known deposits, which, however, are based upon very inadequate data and are therefore probably low, indicate that they might yield 10,000 to 15,000 tons in addition to the 18,000 tons already shipped. The oxides are intimately mixed with silica, so that careful sorting is necessary to produce material containing more than 45% of manganese. After the oxides are sorted they are carted to wharves on the coast and carried by lighters to ships anchored near the shore.—U. S. Geological Survey.

A MINER speaking a foreign language seeks employment from a foreman who can talk to and direct him only in English. He goes underground, where all printed signs are written in English. He receives spoken warnings of dangers and of dangerous conditions from an underground boss, also in English. If he does not make an earnest effort to learn this language he not only puts his own life in danger, but his mistakes through misunderstanding orders may imperil the lives of others.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

OPERATION OF GADSDEN MINE IS DISCONTINUED

JEROME.—It is reported that development on the Silver Tip claim of the Green Monster Copper Co. will be resumed soon. Several winzes are to be sunk to explore the veins opened by previous development on the Silver Tip claim. The Calumet & Arizona Copper Co., chief owner of the Gadsden property at Jerome, shut-down the mine on March 25. Diamond-drilling on the 1200-ft. level had already been discontinued. The pumps are to be drawn and the track taken up. It is estimated that three-quarters of a million dollars has been spent in development work. It is thought that operations will be resumed when the copper market improves. At a recent meeting of the board of directors of the Peak Silver Mining Co. plans were formulated for the future development of the Black Horse group of claims which are located on the Prescott-Crown King road. The Black Horse property has not been worked since 1890. The contract for the sinking of the Venture Hill-Verde Apex shaft from the 280-ft. level to the 500-ft. level has been taken by E. L. Bartholomew.

KINGMAN.—Reports from the Telluride mine at Oatman are encouraging. It is said that the cross-cut on the 430-ft. level has entered 16 ft. of mill-ore, 4 ft. of which assays \$26 in gold, and that small streaks sample as high as \$300 per ton. Drifting is now being done along the richer sections of the vein. It is reported that the Martin Brothers, who have purchased all rights in the Harqua Hala mines near Wenden, are making preparations for sinking the shaft to the 400-ft. level. Recent work in the old workings has opened ore similar to that taken out in the early history of the mine and this ore is to be developed by winzes and drifts.

PATAGONIA.—The new shaft of the Hardshell Mining Co. has now reached 435 ft., although water continues to give trouble. The rock taken from the shaft is mineralized quartzite and porphyry and assays 3.4 oz. silver. Indications seem to warrant the belief that the ore-zone will soon be reached in the shaft. Recently, shipping ore has been discovered on the Bender group of claims adjoining the Hardshell group, a 3-ft. vein of 36-oz. silver ore having been encountered at a depth of 17 feet.

PHOENIX.—The annual meeting of the stockholders of the Arizona Gypsum Co. was held at Phoenix, March 1. The report of the secretary showed that sufficient money had been raised to proceed with the construction of a gypsum-plant for the manufacture of all grades of wall-plaster, solid and hollow building-blocks, and fertilizers.

It is estimated that the plant will cost \$25,000 and will be capable of handling 200 tons of raw gypsum per day.

PRESCOTT.—At the annual meeting of the Kay Copper Co. the president reported that there is now \$6,000,000 worth of ore in sight in the Kay property and that several large bodies of ore had been discovered by the diamond-drill. The shaft is making progress and at the 1000-ft. level a cross-cut will be driven to open the main orebody.

RAY.—According to a circular letter to the stockholders of the Magma Chief Copper Co. exploration on the 300-ft. level of the Sombrero Butte property is progressing satisfactorily, the main drift in this level being in 60 ft. of high-grade ore. This ore is also exposed on the 220-ft. level.

COLORADO

THE ISABELLA MINES CO. WILL RE-OPEN

CRUTTLE CREEK.—Directors of the Isabella Mines Co. at a special meeting held in Colorado Springs, have determined to change the base of operations from the Lee shaft to the Empire State shaft, situated at about the centre of the group. The Lee shaft-house and machinery were recently destroyed by fire of unknown origin, entailing a loss in excess of \$100,000 with insurance of about \$25,000. The Empire State shaft now 1100 ft. deep will be sunk 235 ft. further, to correspond to the 15th level of the Lee, at a depth of 1275 ft. Two new cables 1600 ft. long have been ordered and will be wound at the Empire State shaft immediately upon delivery when sinking will be started. All lessees, ten in number, will be given extensions of their respective leases. The Isabella Leasing Co., recently organized by stockholders of the parent company, had just cut the Larson vein, about midway between the Lee and the Empire State, and grab-samples are said to be above average. The change to the Empire shaft should prove beneficial, as the virgin ground to the west can now be exploited at comparatively small cost. The Maloney and No. 2 veins of the Isabella system will be thoroughly exploited by the Isabella Leasing Co., holding a five-year lease. The Lee will not be entirely abandoned and an electric hoist will be erected for use by the lessees who were mining a good grade of ore from the second level.

LEADVILLE.—Ore from the Dex mine, shipped by lessees to the smelter of the A. S. & R. Co., was reported to be so rich in metallic gold that approximately 100 oz. of the yellow metal was caught when the crushed ore was screened preparatory to smelting. This rich discovery

was 900 ft. at the No. 2 Hex shaft, and while the rich streak is no longer producing as much as when the strike was first made, the lessees are still sacking ore.

The Hilltop discovery, made last fall, is holding up and is pronounced by Sam Doran, superintendent, to be the greatest thing in years. The miners employed during the winter have blocked out an orebody 12 ft. wide and 300 ft. long for more than 50 ft. vertically. Ten tons daily is now hauled to Fairplay for shipment, but with roads open to Leadville 50 men will be employed.

MONTANA

ANACONDA COMPANY HAS ELABORATE PLANS FOR SAFETY WORK.

HELENA.—In the Nigger Hill section west of the city the following mines are now producing ore: the Julia, the Charter Oak, and the Big Dick. In the Julia work of unwatering the mine has been completed, and the shaft is now being sunk from the 300 to the 400-ft. level. An air-compressor and hoist have been put in place. Two carloads of ore recently shipped from this property gave satisfactory returns. The Charter Oak mine, of which P. W. Hopkins is manager, is producing high-grade lead-silver ore, and a shipment will soon be made to the East Helena smelter.

Lump Gulch, 12 miles south of here, is developing activity. At the Liverpool mine a new discovery was made on the 750-ft. level a few days ago. This new orebody is about five feet in width, and averages 40 oz. silver per ton. The Free Coinage mine, another famous producer of silver in the past, has been re-opened and is now producing high-grade ore. This mine is being operated by the Amalgamated Silver Mines Co. Another producer in this locality is the King Solomon mine, operated by P. A. Danaher and Chicago associates.

BUTTE. The plan of the Anaconda Copper Mining Co., which will involve the expenditure of \$1,500,000 for systematic organization to eliminate mine hazards at its properties, has been started with the appointment of the following safety and ventilation engineers: L. Smith, at the Mountain Con. mine; C. G. Sullivan, Belmont; W. W. Hanson, Steward; E. Hogan, Poulin; R. D. Sultzer, Tramway; J. Trewin, Silver Bow; A. C. Bigley, Berkeley; F. W. Standberg, West Gray-Rock; W. S. Bates, Mountain View; A. C. Stevens, Pennsylvania; L. Wells, Leonard; C. W. Cole, West Colusa; F. Galtke, East Colusa; R. Ryburn, Badger; H. J. Wigenstein, Nettie; C. O'Brien, Emma; and R. Richards, Alice. These men will also look after first-aid and mine-rescue work at their respective mines and co-operate with A. S. Richardson, ventilation engineer, and J. L. Boardman of the Bureau of Safety. Paul A. Gow, general manager for the Tuolumne Mining Co., reports satisfactory development work on the 1200-ft. level of the Main Range group. The copper and silver ore on this level shows improvement over that obtained on the 1000-ft. level. Two ore-shoots on the Spread Delight vein were opened while cross-cutting in the direction of the Rory O'Moore vein. The Rory O'Moore had a width of 15 ft. on the

700-ft. level. Ore from the Spread Delight vein assays \$10 per ton. As soon as the 500-gal. electrical centrifugal-pump is in place on the 1200-ft. level, the shaft will be sunk to a depth of 2000 ft. As the shaft goes down cross-cuts will be run from the 1600 and 2000-ft. levels, and then from the 1400 and 1800-ft. levels; 100 tons of ore is being hoisted daily, with 75 men employed.

GREAT FALLS. At the Great Falls works of the Anaconda Copper Mining Co. increased activity is evident in all departments. The ferro-manganese plant will soon operate at full capacity. While only one copper-furnace is working at present, four others will be operating as soon as the necessary repairs can be made. The zinc-department is expected to respond to the attractiveness of the spelter market by making a new production record this month.

LIBBY. Cady, Sheffield & Criderman are planning extensive prospecting on their Automobile group of claims. The Gold Copper property has been traced as the source of the placer gold in Libby creek. H. Brink, W. M. Cady, and A. W. Launsbury are making good progress in developing their group of claims. A 9-ft. vein of quartz heavily flecked with gold-silver has been found on the Lukens-Hazel claim. Good results are expected at greater depth. By dropping to the level of the creek and drifting on the vein a 700-ft. back can be obtained under the present surface opening.

ALHAMBRA. The Carbonate Chief Consolidated Mining Co., backed by Helena and Philadelphia capital, is working the Carbonate Chief, Bell, and other claims from two tunnels. Smelter shipments are expected to commence soon.

NEVADA

GOLD PRODUCERS SEEK SUBSIDY.

MINA.—The main working-shaft on the Simon silver-lead property is now down beyond the 485-ft. point. The last 70 ft. has been driven on ore. This is the first definite proof that the large orebodies developed on and above the 400-ft. level extend to greater depths. Nothing but ore is being hoisted. Cross-cut 603 has been driven for the last 30 ft. through ore with a full breast showing. Drift 607 which also shows a full breast has been driven through ore for 47 ft. Lloyd White, of the firm of Bureh, Hershey & White, visited the property recently to check up on the development work. The firm is engaged in working out the flow-sheet of the mill that is to be built.

On the Simon Contact Mines property the shaft is now down beyond the 300-ft. point. It will be sunk to 400 ft. before lateral work is started. Two shifts equipped with machine-drills are employed.

On the Fagan Consolidated Silver property the shaft is down 100 ft. A station has been cut and a cross-cut now out 16 ft. is being driven to cut the fissure in which the ore was found on the 44-ft. level. The orebody which rakes to the north-east dipped out of the shaft at the 50-ft. point.

TULE CANYON. A humorous, yet pathetic, spectacle is the well-equipped 25-ton milling-plant, including a

24,000-gallon water-tank, now standing complete at a 60-ft. shaft on claims at the upper end of Tule canyon. The vein in the claims was thought to be an immense low-grade deposit of gold ore, the estimates being based on pannings, but after six months work and the expenditure of sufficient money to break the backers of the venture, a few assays have disclosed the fact that the pans did not contain gold. The pannings were taken by old and experienced miners, who persisted in building the mill after early assays had shown no gold, their theory being that the ore would 'pan, but not assay'. This supposed remarkable characteristic of the ore was not explained to

Among the directors are John R. Davis and Harry Stimler. Stimler is general manager.

ARROWHEAD.—It is reported that the final payment on the Arrowhead has been made, which will permit the company to ship a large tonnage of ore sacked at the mine. Sinking of the new shaft soon will be started and it is planned to sink the old shaft an additional 100 ft. The west cross-cut on the bottom level of the Consolidated has penetrated a vein 5 ft. wide assaying \$56 for this width. A drift from the west cross-cut is being driven in a 12-ft. vein yielding low assay returns.

MONTEZUMA.—The shaft of the Montezuma Silver

THE 'ORIGINAL' MINE OF THE ANACONDA COPPER COMPANY AT BUTTE

their financial backers by the miners until the mill was near completion and it was finished in the hope that it could be sold. It is said that there is not a ton of ore in the claims on which the plant stands and southern Nevada mining engineers say the venture is unique, as never before in the history of mining has a 25-ton mill been built and a 60-ft. shaft sunk in a vein in which there is no ore. The principal loser says of possible future ventures in mining: "Never again without an engineer." The first payment of \$10,000 on the Ingalls has been divided into three parts and \$4500 has been paid. Work of increasing the capacity of the mill has been started. It will be the policy of the company to let numerous leases on liberal terms. The company that has taken over the mine is the Silver Hills Nevada Mines Co., incorporated for 1,500,000 shares. The officers are: W. J. Loring, president; Edward A. Clarke, of Boston, vice-president; C. H. Beesley, of San Francisco, secretary-treasurer.

Mines Corporation has been sunk 15 ft. in the rich ore-shoot recently opened at the 165-ft. point. The ore is wider than where it was entered and the value is lower, but for 15 ft. the shaft is in material of high shipping-grade. Shipments from the new find have not been made because of deep snow on the road to Goldfield, the shipping point. A number of deals are pending for the sale of nearby claims. The ore contains considerable copper and the zinc content is increasing.

TONOPAH.—At a meeting of Nevada gold producers a resolution was adopted advocating a tax on gold used for other than monetary purposes, the amount of the tax to be given to the producers. The meeting was addressed by Bulkeley Wells, president of the American Mining Congress, and Fletcher Hamilton, State Mineralogist of California. A committee was appointed to form a Nevada chapter of the American Mining Congress and to raise the Nevada quota of \$5000 for support of the McFadden

bill which was recently introduced in the House of Representatives.

GIBBART.—A tunnel 100 ft. lower than that being driven in the outcrop of the vein has been started by the Gibraltar and at 22 ft. the average value of the ore in the face is \$50.

DIVIDE.—The cross cut being driven on the 100-ft. level of the main shaft of the Divide Extension to open the downward extension of the ore-shoot found in the Caldwell shaft is close to the objective, according to unofficial reports. At the recent Tonopah Divide meeting, which was postponed, George Wingfield had a voting strength of 850,000 shares of the 1,010,800 issued. Sinking of the shaft has been discontinued at a depth of 780 ft. until more powerful hoisting-equipment can be secured. The Sherwood Aldrich-Hayden Stone interests have bought 100,000 shares of the treasury stock of the Belcher, according to official reports. Forty tons of ore recently shipped from the Belcher Extension gave a net return of \$900 and a shipment from the east drift on the 85-ft. level of the Belcher is being prepared. This drift is being driven into Belcher territory from the No. 1 shaft of the Belcher Extension. There is estimated to be 700 tons of ore of shipping grade exposed in the Belcher Extension.

UTAH

NEW CONSOLIDATION OF MILFORD PROPERTIES.

ALTA.—Stockholders of the Alta Consolidated Mining Co. at a special meeting on March 22 voted to increase the capital stock from 600,000 to 1,000,000 shares. The increased stock will be put in the treasury and used to finance the further development at Alta and to clear the company of present indebtedness. It is said that arrangements have been made for financing extensive development for the coming summer through the sale of treasury stock.

PARK CITY.—It is reported that with the last settlement check for January and February, the Daly-West company earned during two months more than sufficient to meet dividend requirements for six months. Since the first of the year the company has been shipping high-grade ore. One lot of 100 tons, recently shipped, averaged \$165 per ton. This is some of the best ore that the property has ever shipped. The shipment amounted to 202,842 lb. and averaged 0.97 oz. in gold, 102.75 oz. silver, 23.6% lead, and 3.47% copper. The Judge Mining & Smelting Co. in its annual report, which is just being mailed to its stockholders, reports that, although hampered by a strike which lasted nearly two months, the company did 2171 ft. of drifting and cross-cutting, and 595 ft. of raising; mined 43,197 tons of ore, and ended the year with a cash balance of \$148,385, as compared with \$72,180 a year ago. The discovery of high-grade milling ore in the foot-wall of the Daly vein was one of the development features of the year. The present rate of production of zinc concentrate, together with the tonnage on hand, assures a capacity run of the electrolytic zinc-plant for the year 1920. Since the first of the year

better prices have prevailed for zinc and approximately 500,000 lb. has been sold and is on its way to the market.

EUREKA.—An assessment of one cent per share has been levied on the capital stock of the Uncle Sam Mining Co. The assessment is delinquent April 22 and sale date has been set for May 17. Seventeen mines in this district shipped 149 cars of ore during the week ending March 19, as compared with 163 cars shipped the previous week. The Chief Consolidated had an output of 40 cars; Dragon Consolidated, 24 cars; Tintie Standard, 20; Colorado, 13; Eagle and Blue Bell, 13; Iron Blossom, 7; Mammoth, 6; Victoria, 5; Gemini, 5; Grand Central, 4; Centennial Eureka, 4; Bullion Beck, 3; Eureka Hill, 1; Swansea, 1; Empire Mines, 1; Sunbeam, 1; Victor Consolidated, 1.

The work of sinking the new shaft at the Chief Consolidated Mining Co. has been stopped temporarily at 1165 ft. in order to permit carrying the concrete-work down to the 1145-ft. point. The shaft-work is reported as progressing more rapidly than it was some months ago, owing to a decrease in the flow of water. Much of the water, which was developed in sinking the first few hundred feet of the shaft, is draining off through the 1000-ft. connection and the present flow is not in excess of 65 gallons per minute. It is anticipated construction of the branch railroad to the Iron King property will be completed within the next few weeks, at which time the shipping of ore, which has already been blocked out, will commence.

At a meeting held recently, the following new officers were selected for the Independence Mining Co.: Alex Mattson, president; P. J. Fennell, vice-president; Harold Schriver, secretary; Robert Kallander, treasurer. The other directors are W. F. Schriver and Enoch Newman. The company has awarded a contract for its main working shaft, which is now down 110 ft. The machinery is said to be sufficient to operate several hundred feet deeper and all necessary buildings have been erected. Up to this time the company's expenditures have amounted to about \$28,000, and, while the present indebtedness is in the neighborhood of \$10,000, there is due the company, for stock sold on the installment plan, about \$23,000.

MUSKOGEE.—At a meeting held March 22, the stockholders of the Moscow Mining & Milling Co. ratified the action of their board of directors in agreeing to a consolidation of their property with the Red Warrior and Beaver Combination properties. Articles of incorporation for the new company were also ratified. The new company will be known as the Moscow Silver Mines Co. with a capitalization of 2,500,000 shares. Of this 1,000,000 shares will be exchanged for the Moscow property; 600,000 for the Red Warrior, and 500,000 shares for the Beaver Combination. Arrangements have been made for the underwriting of 300,000 shares in New York. The officers of the new company are: Fred J. Leonard, president; F. J. Hagenbarth, vice-president; M. B. Johnson, secretary and treasurer; Garrett S. Wilkins, general manager. These with Angus Buchanan of Long Beach, California, will constitute the directorate. The consolidation will

take in about 500 acres of promising ground. It is expected that within thirty days after work is resumed the company will be shipping ore again, work having been suspended pending negotiations.

PHILIPPINE ISLANDS

DEVELOPMENT OF MAGMA PROPERTY

MOUNTAIN PROVINCE.—Development of the Magma property in the Benguet mineral zone is progressing on three parallel quartz lodes that strike north and south. The outcrop has been traced for more than one mile. Work was begun in November 1919 and so far has been confined to trenching and to adits at, or immediately below, the surface. The outcrops and their float which cover some five acres show a consistent average value of \$3 per ton, and it seems from indications in the old Igorot workings that the surface had been carefully picked over for higher-grade quartz. Below the surface, however, the assays point to the presence of high-grade ore. The average value of all samples taken from the orebodies below the outcrop to date is \$33.37 gold and six ounces silver. The latter seems to occur in a ratio of four ounces of silver to one of gold. Of these samples four, taken across 15 ft. of hard quartz, averaged \$23.60, while one taken across 12 ft. of quartz and manganese showed a value of \$101.60. The lower tunnel recently started is 705 ft. vertically below the outcrop, thus affording not less than 1500 ft. of backs. Although there is not a ton of ore 'blocked' on this property the exposure of the lodes on the hillside from the camp to the creek indicate a large amount of possible ore.

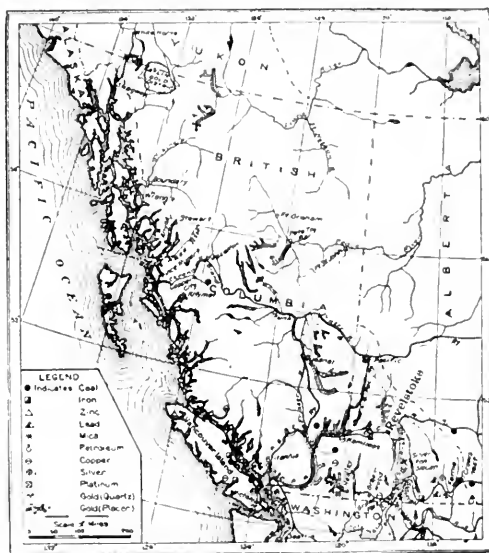

An abundance of good pine timber is available for mining and other purposes on the ridge adjoining the eastern limit of the property. There is from 6 to 8 million board-feet of lumber within easy hauling distance of the proposed mill-site. Native contractors will deliver this at the following prices: round posts 10 in. to 12 in. by 7½ ft. long, each 30c.; round caps 10 in. to 12 in. by 5 ft. long, each 20c.; split lagging, each 3c. Some three miles south of the claims, at a stream junction, a hydro-electric plant can be erected which will produce from 500 to 1000 hp.; and five miles east, on the River Agno, power can be obtained in any quantity up to 30,000 hp. The Philippine government has temporarily reserved the entire Agno basin with the idea of establishing hydro-electric plants for power and light purposes. There is, however, a sufficient supply for mining operations.

The Magma is 15 miles south of the city of Baguio, 5 of which can now be traversed by automobiles. Beyond this point is a government horse-trail for six miles, from which a native trail connects with the mine. While skilled labor is not plentiful, there has never been a shortage for mining purposes up to the present. There is, moreover, a constant supply of native tribesmen, Ifugaos, Bontocs, and Lepantos who, when trained, become fairly good miners. Unskilled labor today costs from 40 to 50c. (gold) per day and skilled labor from 60c. to \$1, which makes the labor cost of operations low.

BRITISH COLUMBIA

THE PROPOSED PLACER ACT

VICTORIA.—The provisions of the proposed legislation to amend the Placer Mining Act may be summarized as follows: In respect of leases, now in arrears for more than one year's rental, the lessee may apply before January 1, 1921, for the consolidation of the annual rentals in arrear and arrange for their payment by annual installments extended over a period not exceeding ten years. Where the arrears are consolidated, the failure to pay the annual installment or the current annual rental when due will automatically result in a forfeiture of the lease. Where the lessee so in arrear fails to apply for consolidation and fails to pay the arrears before January 1, 1921, his lease is forfeited. Provision is made for the issuance of leases, beginning July 1, 1920, at a reduced annual rental and reduced annual expenditure for development

MAP OF BRITISH COLUMBIA

work. The changes in fees in connection with the taking-up and maintaining of leases follow: Hydraulic lease, \$25 instead of \$50 per annum, and development \$250 instead of \$1000 per annum; creek lease, \$37.50 instead of \$75, and development \$250 instead of \$1000; dredging lease, \$25 instead of \$50 per mile and development \$250 instead of \$1000 per mile per annum, the value of any new plant or machinery employed to count as money expended on development; and 50c. royalty to be charged against every ounce of gold recovered.

The D'Arcy Exploration Co., a subsidiary of the Anglo-Persian Co., is again making application for an oil concession in the Peace River country.

PRINCETON.—Construction operations at the Allent and Copper Mountain properties will be resumed by the Canada Copper Corporation about April 1. It will

possible then to start laying track on the new railway from Allenby to the mine, as the grading will be complete. The bridge timbers are being framed at Princeton and will be forwarded to Allenby for distribution. H. R. Van Wageningen, general manager, and Van H. Smith, metallurgist, who have been wintering in the United States, will return soon.

GREENWOOD.—The Providence mine continues to ship. Two cars have been dispatched this month, aggregating 75 tons, most of which was taken from the 400-ft. level. The value is placed at \$14,000. Development now is in progress on the 500-ft. level where there is considerable high-grade ore in sight.

STEWART.—Definite information is available regarding development plans on the Big Missouri group in the Salmon River district. There will be let a diamond-drilling contract for 12,500 ft. Two camps will be maintained throughout the season. The erection of a concentrator and of other equipment will follow, providing the exploration and development give satisfactory results.

TRAIL.—The Consolidated M. & S. Co. is gradually closing down its Emma mine, at Coltern. This mine has produced over 200,000 tons of ore, 47,314 tons being mined in 1918. Up to date during the present year it has shipped 7900 tons. The ore, however, always has been more valuable as a flux for the company's other ores than as a source of copper, the metal content often barely paying the expenses of mining and transportation. No development work was done last year, so, evidently, the company has been contemplating the closing of the mine for some time. The Consolidated company has declared its usual dividend of 2½% for the quarter ending March 31. The cessation of stoping at the Consolidated company's Rossland mines has had a marked effect on the smelter ore-receipts, which, during the past three weeks have fallen off from 30 to 40%.

ONTARIO

SUPPLY OF MINERS AT KIRKLAND LAKE IMPROVES.

TORONTO.—Prospecting throughout the mining regions of northern Ontario promises to be active during the coming season, with a larger number of men in the field than for some years past. The opening of new camps has encouraged the belief that further important discoveries will be made in new or partly prospected areas, and the readiness of capitalists to invest in promising prospects, as shown by the number of new enterprises started in the Boston Creek, Gowganda, Kirkland Lake, and other new fields, has given a decided stimulus to prospecting. The proposed changes in the Mines Act recently announced are meeting with some adverse criticism. The amendment will reduce the fee for staking claims from \$10 to \$5 for those acting on their own account, but will increase it to \$15 where claims are staked on behalf of another. This is not favorably regarded by those who 'grubstake' prospectors, as is frequently done by workmen in operating mines.

COBALT.—The annual statement of the La Rose shows that the company has somewhat improved its position.

The net profit for the year was \$51,736 as compared with \$45,544 in 1918, and the total surplus increased from \$46,646 to \$514,424. Production was maintained in the La Rose from pillars and old stopes, the enhanced price of silver rendering it profitable to work some sections, which could not previously be operated to advantage, and a limited output was obtained from the Violet property. Edwards & Wright, Ltd., which is operating the old Green-Meehan mine, shipped ore during 1919 amounting to 1218 tons, containing 72,569 oz. of silver of the gross value of \$86,648. The Mining Corporation of Canada is extracting a fair amount of high-grade in taking down the party walls between the Buffalo and its other property. It is also obtaining a fair tonnage of milling ore from the Buffalo but has not encountered any new high-grade veins.

The proposed merger between the Adanac and the Victory silver mines has taken a favorable turn, and it is officially stated that operations on the Hylands property of the Victory company to commence in the early spring are practically assured. The basis of the proposed merger is the organization of a new company with an authorized capital of \$3,000,000, one-third to be allotted to the present Adanac shareholders, and one-third to the owners of the Victory property, leaving the remainder for sale to finance development work. Porcupine Crown has resumed production after having been idle since July 1918. With sufficient broken ore to keep the mill running for at least six months, no difficulty is expected in maintaining production at full capacity. Of the 11,609,781 oz. of silver produced from the Cobalt mines during 1919, 5,843,639 oz. was refined in Cobalt, 4,420,538 oz. at Southern Ontario smelters, and 1,345,604 was shipped to plants situated in the United States.

KIRKLAND LAKE.—The working forces of the mines have been considerably increased, many men having been sent here by the Ontario Labor Bureau at Cobalt. A large proportion of these are returned soldiers. The mining companies have put into operation the same wage scale as that adopted in Porcupine, namely, \$4.25 per day for loaders and \$4.75 for miners. At the Ontario-Kirkland about 1000 ft. of lateral work has been done, developing two ore-shoots, one about 200 and the other 100 ft. long, the gold content of which is stated to run from \$10 to \$20. The Pinelle Kirkland Gold Mines, Ltd., has been organized, capitalized at \$4,000,000, to operate the Pinelle group of claims of approximately 700 acres in the eastern part of Lebel township.

MATACHEWAN.—Underground work on the Matachewan mine has been suspended. It is understood that the management has decided to wait until electric power is available before resuming development work. Diamond-drilling will be carried on in the meantime, a contract for 4000 ft. having been let. On the Lake Matachewan property, adjoining, a number of holes have been drilled and the results of assays are stated to be satisfactory. The option held by New York interests on the Robb-Clemens group of claims has been abandoned, as exploration by diamond-drilling failed to show favorable results.

ALASKA

Seward.—Old-time Alaskan miners are preparing to take part in the rush this spring to the new gold-diggings in the Kuskokwim district. Many already have come north in order to take advantage of the sledding conditions of March to get into the district before the ice softens. It is a 600-mile trip by dog-team from Seward to the diggings. From Seward to McGrath, the nearest postoffice and supply point, it is 400 miles. The trail to McGrath follows Rainier pass over the Alaska range to the headwaters of Salmon river, and then up the Kuskokwim river to the trading-station. From McGrath to the diggings discovered last fall it is 200 miles. Prospectors remain at the diggings until supplies are exhausted before making the trip back to McGrath. In March the ice is in such a condition that dog-teams can travel 60 miles per day. In April the ice softens and remains in this condition until June when it goes out and navigation between Seward and McGrath is resumed.

CALIFORNIA

Amador County.—Vello Varrain was killed by gas in the Argonaut mine on March 25, and two other miners had a narrow escape when they descended to the 4500-ft. level to ascertain how much water was in the main shaft. The mine is being flooded in order to stop the fire in the Kennedy mine near-by. The workings of the two mines have communicating tunnels. Ben Sanzuinetti and John Canonica who were with Varrain noticed the gas and being unable to signal the surface climbed out and used the ladder to reach the 3500-ft. level where they telephoned to the surface and were hoisted up. S. M. Kelsey, superintendent, with E. Murphy and E. Sangiffo descended to rescue Varrain. They found him on the 4500-ft. level and carried him to the surface where efforts to revive him failed.

Bedding.—At the Uncle Sam mine near Kennett the Colma Copper Co., which started development work two months ago through the tunnel in the Uncle Sam mine, has put on three shifts. The tunnel will be a mile long and will cut the veins developed by the Mammoth at 600 ft. An important orebody is being developed in the Mammoth mine. A month ago it was reported that 100,000 tons was 'in sight'. The Keystone mine of the United States Smelting, Refining & Mining Co. is said to be showing up well under development.

IDAHO

Adair.—Four feet to the round is being made by the Montana-Idaho Copper Co. in the tunnel which has now reached a point between 5700 and 5800 ft. from the portal. A special meeting will be held in Spokane in April to vote on a proposed change in the capitalization from \$600,000 to \$2,500,000. The purpose of the increase is to provide funds for the electrification and further equipment of the mine and the erection of a concentrating plant.

Coeur d'Alene.—The Caledonia Mining Co. has declared its monthly dividend of \$26,050, according to Stanley A. Easton, president. This is at the rate of one cent per share on the issue of 2,605,000 shares. The Federal Mining & Smelting Co. has now 425 men employed at the Morning mine and is signing up new men as fast as they apply. The capacity of the plant is between 650 and 700 men. The mine

is reported to be in excellent shape and ready for record production. The orebodies on the lower levels are exceptionally good and contain less zinc than those on the higher levels. A new orebody rich in galena, said to be 12 ft. wide, is being developed on the 2000-ft. level, the deepest level being worked at present. This orebody will assay from 30 to 50%, lead with good silver content. Plans are being made to sink to the 2200-ft. level.

Lakeview.—Henry Gallan and C. G. Ferrell have taken a lease on the Conjecture and Spider groups adjoining the Weber mine. The lease carries with it an option to purchase the property for \$70,000.

MONTANA

Basin.—New development work at the Jib mine has resulted in the exposure of considerable high-grade ore. Two of the shoots are said to be 20 ft. wide, and it is estimated that 250,000 tons of ore has been exposed. Sinking of the three-compartment shaft at the Katie to a greater depth will be carried on simultaneously with the construction of a new 600-ton concentrator, according to reports. When operations are in full swing it is estimated that several hundred men will be employed at the plants of the Jib, Hope, and Katie mines, which comprise the holdings of the company. R. C. Gemmel, general manager for the Utah Copper Co., with a party of engineers and Eastern financiers visited the properties last week, presumably with a view to financing future operations.

Butte.—The Anaconda Copper Co. is still short of experienced miners. While repairing and fire-proofing some of the idle shafts, the company is producing at 75% of the normal rate. The North Butte company produced 2,000,000 lb. of copper in February. The Butte & Superior company in January and February produced about 11,000,000 lb. of zinc and 210,000 oz. of silver. The East Butte company is reported to have cut a fine body of ore on the 1800-ft. level. The Davis-Daly company is drifting on a vein cut in the station on the 2700-ft. level, where 11 ft. of 6% copper ore is reported. It is possible that the Silver King, west of town and south of the Gagnon, may be opened.

Neihart.—The Cascade silver mine is said to be earning \$35,000 to \$40,000 per month.

Potomac.—The Potomac Copper Co. has 2 to 5 ft. of native copper and copper glance in a fault fissure. The Scratch Gravel mine, situated at Philipsburg, shipped a car of silver ore last week that netted \$4700 and another that netted \$900.

NEVADA

Kimberley.—The sinking of the Alpha shaft an additional 100 ft., as decided upon last year, has been completed. Further diamond-drilling will, however, be done before cross-cutting to the ore-zone, since drilling to date indicates that the ore at this level is oxidized. As the upper levels of the Alpha mine contain large quantities of direct-smelting ore, there is, of course, no advantage in opening up new levels until the sulphide zone is reached. Diamond-drilling from the 1300 and 1400-ft. levels of the Alpha mine is being pushed as rapidly as possible. Three drills are now at work, and the immediate shipment of a fourth has been ordered. Work on plans for the new reduction-works is progressing.

MR. HOOVER ON THE REPORT OF THE INDUSTRIAL CONFERENCE

On March 21 Mr. Hoover made the following comment on the report issued by the Industrial Conference, of which he was acting chairman:

"The background of the Conference report is a policy of 'get together' for joint settlement, with pressure to bring it about where the parties were unwilling. The Conference considered that modern industry, as conducted in large establishments, had caused a loss of personal contact between employers and employees. It, of course, makes possible the greater production that has made our high standard of living. Direct personal contact, in the old manner of smaller units, with the sense of personal responsibility for the interest of both sides, cannot be restored.

"The Conference, therefore, believes that the just, human relationships between the employer and the employee can only be promoted by deliberate organization to bring them together. It feels that a new American basis of industrial relationships has been developing during the last two or three years in the widespread and deliberate organizations of these relations between employers and employees in many hundred establishments through the country on a democratic basis.

"The plan involves but small Government expenditure and but little extension of permanent public officials. A board of nine members at Washington, together with twelve Regional Chairmen, comprise all there is to this basic machinery. It is interesting to note that so great an authority as the Hon. William L. Mackenzie-King, former Minister of Labor of Canada, who has been largely responsible for the origin and administration of the Canadian industrial procedure, considers the plan put forward by the Conference as a constructive improvement on all others hitherto proposed.

"The report probably will not meet with the approval of the extremists on either side, but it has been approved in its broad lines by many hundreds of employees and many prominent labor leaders who have been consulted or communicated with. The Conference believes that it will appeal to those who believe in sane and sure steps to advance human relations in industry. It will be interesting if critics will read the entire document before they launch forth criticisms. It would be even more interesting if political leaders would state their agreement or disagreement with it."

RESOLUTION ADOPTED BY MONTANA SECTION OF A. I. M. & M. E. ON MARCH 5

Whereas, There is at this time a strong and wide-spread sentiment for Herbert C. Hoover for President of the United States; and

Whereas, Hoover, by his work in Europe, has shown executive and administrative abilities of the highest order, particularly fitting him for handling both the economic problems of reconstruction at home, and our relations with other nations; and

Whereas, The Montana Section of the American Institute of Mining and Metallurgical Engineers has a patriotic duty to perform at this time, not only as representing engineers, but also as a representative body of American citizens; be it therefore

Resolved, That the Montana Section, representing 217 engineers in Montana, endorses Herbert C. Hoover for President

Committee on Resolution

Reno H. Sales, Chairman

Charles H. Clapp

Norman B. Brady

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. B. Lakenan is in San Francisco.

Herbert W. Pudan has gone to Sinaloa, Mexico.

Bond Coleman has left El Paso for Zacatecas, Mexico.

Frank L. Sizer has returned from Randsburg, California. B. A. Barton has left Korea and is now at Malvern, Victoria.

W. C. Loughlin has returned from Sonora, Mexico, to Los Angeles.

Knox & Allen have moved their office to 160 Broadway, New York.

James W. Neill was seen on the Claremont golf-course last Wednesday.

W. E. Defty, of Phoenix, Arizona, was in San Francisco during the week.

Ben. B. Lawrence is recuperating from an accident at Augusta, Georgia.

R. C. Gemmell has returned to Salt Lake City after a trip to New York and Washington.

Augustus Locke has returned to San Francisco from New York, after a trip to Arizona.

John T. Towers, of Seattle, is operating a copper property on Kupri duof island, south-eastern Alaska.

D. C. Jackling is in New York. He visited the Ray and Chino properties in Arizona and New Mexico.

H. J. Sheafe has been put in charge of War Minerals Relief work for the U. S. Bureau of Mines, on the Pacific Coast.

David Cole of El Paso was recently in the Globe district on professional work connected with the Iron Cap Copper Co.

L. C. Hill, engineer on the staff of the Rio Tinto mine, in Spain, has been making a tour of the mines of the Southwest.

F. P. Knight, president, and Roland H. Knight, secretary and treasurer of the Iron Cap Copper Co., are in the Globe district.

J. M. Sully, general manager for the Chino Copper Co., has been in New York, Boston, and Washington. He has returned to Hurley, New Mexico.

E. W. Fredell has been appointed superintendent for the Arizona Hercules Copper Co., in charge of the milling and power plants, at Hercules, Arizona.

Charles A. Mitke was in the Jerome district for several weeks recently, where he was engaged in professional work for the United Verde Extension Mining Co.

W. D. Thornton, vice-president, and L. D. Ricketts, consulting engineer for the Inspiration Con. Copper Co., are making a visit of inspection to that property.

Dale L. Pitt, formerly ore-buyer for the Tacoma smelter, has been appointed general manager of the Premier mine in the Salmon River district, British Columbia.

Hugh R. Van Wageningen, general manager for the Canadian Copper Corporation at Princeton, British Columbia, has been visiting the mines of the New Cornelia Copper Co. at Ajo.

E. C. T. Pelham, formerly district sales-manager for the Denver Rock Drill Co., with offices at El Paso, and now connected with the Denver office of the company, is in Mexico City.

Zeal J. Chamberlain, one of the oldest and most valued employees of the Ludlow-Saylor Wire Co., died on March 20 at the age of 41 years. He was well known to business associates all over the country, having represented his firm for nearly 30 years.

THE METAL MARKET

METAL PRICES

San Francisco, March 30

Aluminum dust, cents per pound	6.5
Antimony, cents per pound	11
Copper, electrolytic, cents per pound	9.50-10.30
Lead, pig, cents per pound	8.14
Platinum, pure, per ounce	816
Platinum, 10%, tridium per ounce	82.5
Quick-silver per flask of 75 lb	10
Spelter, cents per pound	12.50-13.00
Zinc dust, cents per pound	12.50-13.00

EASTERN METAL MARKET

(By wire from New York)

March 29—Copper is more active and stronger. Lead is quiet and easier. Zinc is inactive and steadier.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 990 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

The reports that have lately obtained currency in London and New York as to the impending export of gold on a large scale to the United States afford many opportunities for surmise and speculation as to the future of gold. At the same time, it is both helpful and interesting to recall some features of the recent history of the metal since the producers of South and West Africa were permitted a free market for the sale of their commodity, says the "Financial Times."

When the first advance gold under the new arrangement reached the London market last September the most adverse exchange to this country was that of New York, the dollar being then at a premium of approximately 15% against its parity of \$4.8665 to the pound sterling. Further, the price at which gold was exchangeable for dollars was still \$20.67183 sterling. It was naturally anticipated that a large proportion of the gold available from time to time would find its way to New York. In point of fact, it is doubtful if 1% of the total gold marketed in London since September last has reached the United States of America. Since the latter part of October, apart from nominal quotations when no deal was taken place, the price of gold has not once been fixed at a figure at which its export to New York would have been immediately profitable on either a large or small scale.

What, then, are the factors that have contrived to negative these early anticipations? The Indian government, faced with the necessity of providing for its currency demands, has resorted to extensive purchases of gold, which have been continued until a recent date, and it may be stated that the greater portion of the free gold accordingly has found its way directly to India.

Other important purchasers have been Argentina, Straits Settlements, South Africa, Spain, Switzerland, and, in a lesser degree, Holland and France. Since the recent adoption by the Secretary of State of the report on Indian currency the India Council seems to have retired from the field for the time being, the premium on gold in the bazaars having fallen considerably, and in the absence of this most important competitor it is considered doubtful whether, apart from the United States, other buyers will entirely absorb the available supplies. With exchanges at their present level the potential destinations of gold are the United States, Argentina, Japan, India, Spain, Straits Settlements, and Switzerland.

In a lesser degree some other Continental countries are both possible and probable buyers, but not as exchange propositions. As the situation stands at present exporters to Argentina are in a position to offer better terms than other competitors, buying gold as a cover against the sale of exchange, but it is questionable whether purchases for this quarter are capable of absorbing an average of 150,000 oz. per week, while the resultant offering of exchange on Argentina would tend to reduce the value of the gold peso in sterling to a level corresponding to that of the United States dollar. So far free gold has not been engaged for shipment to Japan. Competition from this quarter, if it materializes, is not likely to be very serious, while the remarks in reference to Argentine importations apply with even greater force to Japan. At the same time the exportation to the United States will doubtless take place.

Foreign quotations on March 30 are as follows:	
Sterling, dollars: Cable	3.87 1/2
" Demand	3.86 1/2
France, cents: Cable	6.71
" Demand	6.73
Lire, cents: Demand	4.88
Mark, cents: Demand	1.45

Eastern Metal Market

New York, March 21

Only moderate activity characterizes most of the non-ferrous markets, prices in some still being erratic.

After receding to what appears to be a low level on this movement, prices for copper are recovering and demand is better.

There is a much more active interest in tin by regular consumers and buying has appeared in volume at fluctuating prices.

Lead has eased off in price and requirements are less urgent.

Zinc prices still float up and down daily with fair buying at the low level.

Antimony is quiet and strong.

IRON AND STEEL

The Steel Corporation continues to sell for second-half delivery at the prices of March 21, 1919. Independent producers still get higher prices in all lines.

In view of all the handicaps, production continues so large that the accepted estimates of capacity are being revised upward. Railroad buying has been disappointing, apart from the first show of activity in the few days following the return of the lines. Fresh shipbuilding enterprises still appear. Demand for structural material has dwindled. Occasional cancellations, now somewhat emphasized, are not necessarily different from those seen at other times. Sales aggregating about 12,000 tons of steel-making and foundry pig-iron have been made for export and further sales are pending.

COPPER

Up to the end of last week the copper market declined until electrolytic reached a level of 18c., New York, for deliveries up to July 1. This appeared to attract some consumers and some buying is reported to have been put through. Since then quotations have advanced until today the same brand is held at 18.50 to 18.75c., New York, for the same positions. Lake copper is now around 18.87½ to 19c., New York. More interest is manifested by consumers and the tone of the entire market is stronger and brighter.

TIN

Consumers have at last become interested and the market reveals a different aspect. The speculative phase, so long dominant, is disappearing. Last week there was again a fair business between dealers and on March 18 there appeared a heavy inquiry from consumers who exhibited a strong desire to buy. This was partly due to a heavy drop in the London market of £23 to £24 per ton on that day—down to £33½ for spot Straits—as compared with a high of £41½ per ton a few weeks ago. Sellers here, however, became reluctant to part with their metal, scenting the market at its low point, which has been justified by later developments. Much more tin could have been sold on that day had there been the sellers. As it was, about 300 to 400 tons changed hands for all positions and at prices well above import cost, which is termed a feature of present conditions. On March 18 the price spread was wide, spot Straits selling as low as 58.25c., New York, and as high as 59.62½c. On March 22, the price spread was equally wide, spot Straits selling at 61.30 to 61.75c., New York, with futures sold at 63c. On March 23 there was a good inquiry, partly influenced by a break of £9 in the London market where spot Straits was quoted at £24½ per ton and futures at £31½. Yesterday spot Straits was quoted at 60.75c., New York. A fair business resulted. Arrivals thus far this month have been 2,605 tons with the quantity afloat reported as 3585

tons. The exportation of 50 tons to Hamburg, Germany, is of interest.

LEAD

With prices strong and the tendency apparently higher, the market last week was somewhat startled by offerings by a leading independent producer of lead at 9c., New York. Partly as a result of this and partly because of the more normal conditions of transportation, releasing some of the large quantities of lead in transit, the market is easier and quiet. For early delivery the metal is obtainable at 8.75c., St. Louis, or 9c., New York, from outside sellers, with the leading interest at 9c., St. Louis, or 9.25c., New York.

ZINC

The intimate relation, sentimentally at least, between the American market and the London continues to be the feature. The foreign market has continued its speculative trend and is very erratic, up one day and down the next. As a consequence quotations here for prime Western have fluctuated in the last week from 8.50 to 8.87½c., St. Louis, for delivery to July 1. At the lower prices a fair domestic business has been done each time. Yesterday quotations were 8.50c., St. Louis, or 8.85c., New York, with the market quiet. Inquiry is moderate and so is the tonnage changing hands. Export business at present is dull. Leading producers are not anxious to sell on the dips and are comfortably situated.

ANTIMONY

For the better grades of antimony quotations are firm at 11.50 to 11.75c., New York, duty paid, for wholesale lots for early delivery. The market is quiet.

ALUMINUM

Virgin metal, 98 to 99½ pure, in wholesale lots for early delivery, is quoted at 31c., New York, and in the outside market and at 32c., by the leading producers.

ORES

Tungsten: The tariff bill continues the centre of attraction, but there are some who still insist it will never become a law. The Senate Finance committee has reported the bill favorably but with certain changes. The tariff on ore and concentrates is to be \$9 and on ferro-tungsten, tungsten powder, etc., 0.9c. per pound of material for each per cent of tungsten contained, with the present advalorem of 15% retained; on high-speed and alloy steels 35% advalorem is to be retained, making a total of 50% advalorem. Consideration of this is expected in two weeks.

Ferro-tungsten is quoted at 80 to 90c. per pound of contained tungsten.

Molybdenum: The market is inactive with prices nominal at 75c. per pound of MoS₃ in regular concentrates.

Manganese: Some Indian ore as well as Chilean and Java ore of good grade probably will be soon available. The last important sale of foreign ore was 15,000 to 20,000 tons of Indian ore to a large American producer of ferro-manganese. Prices range from 65 to 80c. per unit, depending on the ore, the quantity, and the delivery.

Manganese-Iron Alloys: Inquiries for early delivery ferro-manganese are fairly numerous, greater in fact than the supply of the alloy. While no spot sales were reported during the last week, it is freely admitted that almost any price from \$230, delivered, up, could be obtained. The most significant information of the week is the fact that British supplies of manganese ore are not being received as calculated and that as a consequence one British representative here is advised that deliveries of alloy on contract to American consumers will be delayed. This may have a decided influence on the course of the market here. Spiegeleisen is strong at \$60, furnace, with foreign inquiries predominant.

Company Reports

RAY CONSOLIDATED COPPER CO.

Report for the quarter ending December 31, 1919.

Property: mine at Ray, and concentrator at Hayden, Arizona.

Operating Officials: William S. Boyd, manager; Charles A. Smith, mine superintendent; William T. McDonald, mill superintendent.

Financial Statement: net operating profit, \$641,378; miscellaneous income, \$5848; total, \$647,226 as compared with \$932,147 for the preceding quarter.

Dividends: \$788,589.50; total to date, \$23,835,430.

Development: current underground development for the quarter totaled 7012 feet.

Production: 11,614,647 lb. of copper was produced from 397,100 tons of ore averaging 1.813% copper; milling cost was \$1.42 as compared with \$1.33 for the previous quarter. The average cost of copper was 16.57c exclusive of credit for gold and silver. Operations during the quarter were conducted at one-half capacity.

THE TENUSKAMING MINING CO., LTD.

Report for the year ending December 31, 1919.

Property: mines and claims in North Cobalt and Porcupine districts.

Operating Officials: Gordon F. Dickson, general manager; J. W. Moffitt, mine superintendent.

Financial Statement: proceeds from ore sales, \$230,838; estimated ore on hand December 31, 1919, 892,035; ore on hand December 31, 1918, 827,621; net earnings, \$295,253; operating expense, \$268,253; net profit, \$31,996; miscellaneous income, \$66,072.

Dividends: dividend No. 25, \$100,000; total dividends to date, \$2,225,000.

Development: 2283 ft. of development work was performed; rich ore was discovered in the southern extension of the vein system in the Gans area.

Production: 15,899 tons of ore milled produced 243,037 oz. of silver with an extraction of 88.6%; total cost of mining and milling, \$11.71 per ton.

DAVIS-DALY COPPER COMPANY

Report for the quarter ending December 31, 1919.

Property: mine at Butte, Montana.

Operating Officials: James L. Bruce, general manager; William Frazier, mine superintendent.

Financial Statement: returns on ore, \$477,455; miscellaneous revenue, \$33,037; total expense, \$339,238; cash and quick assets on December 31, \$569,571.

Dividends: \$300,000 on December 29; total to date, \$750,000.

Development: 1825 ft. of this character of work was done during the quarter. Indications on the 2700-ft. level are favorable.

Production: 25,989 tons of ore hoisted produced 3,594,391 lb. of copper and 145,616 oz. of silver; the ore shipped averaged 6.72% copper and 5.59 oz. of silver per ton. Improvements in surface equipment are under way.

VINDICATOR CONSOLIDATED GOLD MINING CO.

Report for the year ending December 31, 1919.

Property: mines in the Cripple Creek district and a controlling interest in the Ferro Alloy Company; also the La Bella mill.

Operating Officials: George A. Stahl, general manager; W. E. Ryan, general superintendent; A. R. Minner, mill superintendent.

Financial Statement: proceeds of ore sales and royalties \$681,411; miscellaneous income, \$10,631; mine and mill

operations, \$609,000; expenses, operating profit, \$1,014,181; profit from Ferro Alloy operations, \$7488; total operating profit, \$818,669. Deducted for depreciation and depletion, \$115,841; balance, \$702,828; excess of \$19,866 over the operating profit. Quick assets on December 31, 1919, \$765,848.

Dividends: during 1919 amounted to \$60,000, making a total to date of \$2,832,500.

Development: 7622 ft. of development work was done during 1919, including 1200 ft. of diamond-drill work. Prospects on the 1800 and 1900 ft. levels are good. Ore reserves on December 31 are estimated at 46,440 tons.

Production: during the year 1919, 143,400 tons of crude ore was hoisted on company account through both shafts, from which was produced 19,922 tons of shipping product, with a gross value of \$718,137; the marketing charges on which were \$129,251, and the net returns \$588,885. There were hoisted on lessees' account \$55,618 crude tons; and shipments from this source totaled 20,772 tons, with a gross value of \$291,965, marketing charges on which were \$104,712, leaving a net value of \$186,253. The company's royalties on lessees' shipments amounted to \$22,525.

THE PORTLAND GOLD MINING CO.

Report for the year ending December 31, 1919.

Property: Portland and Independence mines and the Independence mill in the Cripple Creek district, and the Portland mill at Colorado Springs.

Operating Officials: George M. Taylor, general manager; Fred Jones, mining engineer; Thomas B. Crowe and J. M. Tippet, metallurgical engineers.

Financial Statement: gross value of ore mined and shipped, \$1,272,720; proceeds from Independence mill, \$513,875; miscellaneous revenue, \$6293; cost of mining and milling, \$1,562,600; net profit from operation, \$230,290.

Dividends: \$240,000 during 1919; total to date, \$11,197,080.

Development: the mines have been opened a depth of 2300 ft., where a station and pumping equipment has been completed. Good ore is being blocked out on the 20th and 21st levels.

Production: 373,192 tons of ore was produced during 1919.

LAKE SHORE MINES LIMITED

Report for the year ending November 30, 1919.

Property: gold mine and mill in the Kirkland Lake district.

Operating Official: R. C. Coffey, mine manager.

Financial Statement: bullion production, \$294,514; miscellaneous income, \$13,017; total expense, \$209,278; provision for exhaustion, \$60,000; net profit, \$38,273.

Dividends: \$100,000; total to date, \$200,000.

Development: a total of 1864 ft. of drifts and cross-cuts on the 200 and 400-ft. levels was performed.

Production: the mill was shut-down for four months on account of labor troubles, being re-started in October; 11,907 tons was milled with a recovery of \$24.67 per ton.

BUTTE & SUPERIOR MINING CO.

Report for the quarter ending December 31, 1919.

Property: mine and mill at Butte, Montana.

Operating Officials: Charles Bocking, general manager; E. V. Daveler, general superintendent; Angus McLeod, mine superintendent.

Financial Statement: operating costs, taxes, etc., for the quarter, \$1,182,581; profits, \$566,984.

Dividends: none during 1919; total to date, \$16,910,258.

Development: development work included 3669 ft. of drifting, 1677 ft. of cross-cutting, and 967 ft. of raises; no shaft-sinking was performed during the quarter.

Production: 125,921 tons was mined and milled, having

10.50% zinc content of 14.916%, and silver content of .341. Direct mining cost was \$6,125, direct milling cost, \$16, both of which figures showed an improvement over the previous quarter. Milling operations in which more than 100 tons of oil was used in flotation produced concentrate averaging 54.74% zinc and 19.537 oz. silver.

ALASKA GOLD MINES CO.

Report for the quarter ending December 31, 1919.

Property: control of the Alaska Gastineau Mining Co. owning mines, concentrator, and hydro-electric power plant at Juduan, Alaska.

Operating Officials: George T. Jackson, manager; D. J. Argall, mine superintendent.

Financial Statement: gross value of bullion and concentrate produced \$115,352; total operating expense, \$503,953; miscellaneous income, \$4928; operating loss, \$84,572.

Dividends: none to date.

Development: 738 ft. of development consisted of driving manway-raises and bulldozing-drifts preparatory to opening new stapes.

Production: tons milled, 692,534; value per ton, \$9.75; amt. of gold recovered, 600. per ton.

THE NATOMAS COMPANY OF CALIFORNIA

Report for the year ending December 31, 1919.

Property: gold-dredging land in Sacramento and Butte counties, California.

Financial Statement: gross returns from dredging, \$1,775,124, cost, \$1,313,640; net returns, \$461,484; other income, \$570,180; expense, including bond interest, \$864,117; net operating profit, \$167,548; current assets, \$1,036,335.

Production: 11 gold-dredges were operated during the year; 20,485,000 cu. yd. of gravel containing 8.66c. per cubic yard was handled at a cost of 6.41c., leaving a net profit of 2.25c. per cubic yard. Some income was derived from dredging land not owned by the company.

THE VICTORIA COPPER MINING CO.

Report for the year ending December 31, 1919.

Property: mines and mill in Ontonagon county, Michigan.

Operating Officials: George Hooper, superintendent; Charles D. Hooper, mill and power superintendent.

Financial Statement: proceeds from copper sold, \$39,152; inventoried value of copper on hand, \$208,537; miscellaneous income, \$14,907; total expense, \$299,455; excess of expenditures over receipts, \$36,857; cash assets, \$262,334.

Dividends: no dividends during 1919.

Development: No. 2 shaft was finished to the 28th level; favorable developments are noted on the 23rd, 24th, and 27th levels from this shaft, where 1908 ft. of development was performed during 1919.

Production: 105,600 tons of ore was hoisted, of which 89,206 tons was stamped. The yield of refined copper was 1,245,000 lb., of which 330,000 lb. is the estimated production from ore not yet smelted. The yield was 14 lb. of copper per ton of ore stamped.

BINGHAM MINES COMPANY

Report for the year ending December 31, 1919.

Property: the Dalton & Lark and Commercial mines at Lark, Utah; control of the Eagle & Blue Bell Mining Co. and the Yosemite Mines Co.

Operating Official: Joseph Hyland, superintendent.

Financial Statement: net receipts from ore shipments, \$138,553; royalties and rentals, \$42,792; gross earnings, \$181,146; operating expense, \$111,972; mine development, \$26,405; income from dividends, \$41,928; net gain for year, \$80,366; surplus, December 31, 1919, \$261,231.

Dividends: \$112,500 during 1919; total to date, \$600,000.

Development: new work at Lark, totaling 1358 ft. Prep-

arations have been made to explore the Lark vein below the Mascot tunnel. Favorable development on the Brooklyn was accomplished. At Tintic, development was curtailed on account of the unfavorable lead market, the most important work being done on the south end of the 1250-ft. level.

Production: 26,561 tons of ore containing 2049 oz. of gold, 191,006 oz. of silver, 1,939,737 lb. of lead, and 636,515 lb. of copper from the Bingham mines. At the Eagle & Blue Bell mine 23,003 tons of ore containing 1642 oz. of gold, 389,536 oz. of silver, 55,060,000 lb. of lead, and 467,364 lb. of copper was produced.

HOLLINGER CONSOLIDATED GOLD MINES, LIMITED

Report for the year ending December 31, 1919.

Property: mine and mill at Porcupine, Ontario.

Operating Official: A. F. Brigham, general manager.

Financial Statement: bullion produced, \$6,722,267; miscellaneous income, \$340,832; general charges, \$303,563; mining, \$2,053,219; milling, \$865,844; total, \$3,222,617; operating profit, \$3,840,482; taxes, depreciation, etc., \$1,519,192; net quick assets, \$3,602,554.

Dividends: during 1919, \$1,722,000; total to date, \$11,146,000.

Development: total sinking, drifting, cross-cutting, and raising, 22,643 ft.; diamond-drilling, 37,868 ft.; underground ore-reserves on December 31 estimated at 4,178,000 tons with a value of \$37,817,000, in addition to 2,000,000 estimated from surface outcrops.

Production: 711,882 tons was milled; average value per ton, \$9.73; net value recovered, \$6,722,267; average tons per day, 1950; value of tailing, 33c. per ton; total mining charges, \$2.884 per ton; total milling charges, \$1.216 per ton.

TECK HUGHES GOLD MINES, LIMITED

Report for the year ending August 31, 1919.

Property: mine and mill in Kirkland Lake district, Ontario.

Operating Official: E. L. H. Forbes, general superintendent.

Financial Statement: bullion production, \$149,875; operating expense, \$162,661; miscellaneous expense, \$67,756; operating deficit, \$80,542; quick assets, \$58,580.

Dividends: none to date.

Development: 1441 ft. of development work opened new ore on the 2nd, 4th, and 5th levels. Reserves are estimated at 26,000 tons, averaging \$10. This is more than was known to be available at the corresponding date in 1918.

Production: 16,907 tons of ore with an average gross value of \$10.27 per ton produced \$149,875. Operating conditions were unfavorable during the year.

NEVADA CONSOLIDATED COPPER CO.

Report for the quarter ending December 31, 1919.

Property: mines, mill, and smelter near Ely, White Pine county, Nevada.

Operating Officials: C. B. Lakenah, general manager; Robert Marsh, Jr., mine superintendent; George C. Riser, mill superintendent; R. E. H. Pomeroy, smelter superintendent.

Financial Statement: operating profit, \$403,331; other income, \$283,958; net gain, \$687,290.

Dividends: \$749,796; total to date, \$45,269,024.

Development: of the tonnage milled, 62% was supplied from the pit and 38% from the underground workings of the Ruth mine.

Production: 592,953 dry tons, averaging 1.55% copper, was milled, in addition to 57,451 dry tons of custom ore. The cost of production, including depreciation, was 18.64c. per pound of copper. Precious-metal recovery amounted to 2.51c. per pound of copper.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

AERO BRAND CYANIDE

Aero Brand cyanide, grade X, made from the air at Niagara Falls, is the cheapest form of cyanide on the market. In its manufacture two low-costing raw materials, cyanamid (air-nitrogen) and common salt, are fused in an electric-furnace. The molten product is then run over a special cooling device and into drums, ready for shipment. The low production cost, plus a nominal selling expense and moderate profit, permits of a selling price much below the quotations for any other grade of cyanide. Aero Brand cyanide at present contains upward of 36% sodium cyanide, equivalent to approximately 48% potassium cyanide. The other components are: about 1% calcium cyanamid, about 5% of insoluble matter, 15% of caustic lime, and 43% of chlorides

ture in the air may cause decomposition and consequent escape of cyanide fumes. It is not advisable to grind the flaked cyanide in a dry form on account of this probable loss. The flaky nature renders its solution in water extremely easy and there is no need of further grinding in order to obtain solution. Aero Brand cyanide, pound for pound of contained cyanide, is equal in efficiency to the 96 to 98% grade. The soluble salts present other than cyanide, owing to their coagulating effect on the slimes, materially assist the settling operations and reduce the time required for clarification and filtration. The lime present helps to maintain the protective alkalinity of the solutions. The slight amount of soluble sulphides give no trouble in practice, as the air-agitation used in the leaching tanks quickly removes

Plant of the American Cyanamid Co. at Niagara Falls

of lime and sodium. Pound for pound of contained cyanide Aero brand is equal in efficiency, for all purposes, to cyanide in any other form or grade.

The first successful experiments on the fixation of air-nitrogen were begun about 25 years ago, with the object of producing cheap cyanide. Instead of cyanide, however, another chemical (cyanamid) was obtained. This proved so useful as a fertilizer that the cyanide process was temporarily abandoned. In 1916 the American Cyanamid Co., whose production of air-nitrogen products at Niagara Falls had reached an annual value of over \$6,000,000, undertook to convert cyanamid to cyanide. The manufacture of Aero Brand cyanide was begun January 1, 1917. Consumption in the first year of its manufacture reached a total of 2,316,420 lb. of sodium cyanide. In 1918 consumption was increased to 2,577,920 lb. In 1919 the consumption exceeded 3,500,000 lb. Additional equipment is now being installed for increasing the production, to keep pace with the demand from both the mining and chemical fields.

Aero Brand cyanide is marketed in the form of small brittle flakes of a grayish-black color, about $\frac{1}{8}$ in. thick and from $\frac{1}{16}$ to $\frac{1}{4}$ in. diameter. On account of its flaky form, and consequently the large surface exposed to the air, it should not be allowed to stand in open containers longer than necessary before discharging into the solution tanks. The mois-

ture. The insolubles have no precipitating or other deleterious effect in the leaching operation, as has been demonstrated by practice covering three years operation. The consumption of zinc is the same with Aero Brand cyanide as with high-test cyanide. It is ordinarily introduced, like other grades, directly into the agitation tanks. Where grinding or in solutions is practised, the cyanide solution behaves in the same manner as with any other grade of cyanide. The making up of very concentrated solutions of Aero Brand cyanide is not recommended. The necessity of using sufficient water to dissolve all the solids usually operates against this practice.

Aero Brand cyanide has been successfully used in the treatment of many varieties of ore. Experience has shown it can be used in the same manner as the 96 to 98% grade, with the exception of a few special cases requiring unusual treatment.

MOLYBDENUM

Molybdenum owes its name to the word 'Molybdaena', under which title most minerals resembling lead in appearance were known in the eighteenth century. It is a metallic element reduced chiefly from the sulphide molybdenite (MoS_2), which is a mineral very similar in appearance to

graphite. Molybdenite and other molybdenum-bearing ores are found widely distributed throughout the world.

The metal (Mo) resembles platinum in general physical appearance, although it is darker and possesses a peculiar lustre. Its atomic weight is 96, its specific gravity about 9, its specific heat about 0.07, and it melts at about 2550°C. Despite the very high melting point of metallic molybdenum, it alloys readily with iron, the ferro-molybdenum having a melting point of approximately 1470°C. It resists most acids and chemicals to a marked degree.

The molybdenum-bearing ores are found widely distributed; the metal up to a few years ago was classed as semi-rare or semi-precious, as no deposits of real commercial magnitude had been discovered. A few years ago the Climax Molybdenum Co. acquired possession of a deposit of molybdenum sulphide (molybdenite— MoS_2) at Climax, Colorado, north-east of Leadville. This orebody, by far the largest known, is of such extent and magnitude as to make molybdenum commercially available on a scale sufficient to meet all requirements of the steel trade.

The flotation mill, at Climax, to treat the crude ore, has at present a capacity of 1000 tons per day, and at this rate of production, the ore-reserves already developed—in this one deposit alone—ensure steady operation for more than thirty years. The entire orebody has not been developed as yet. The ore is broken, delivered to the mill by aerial tramway, ground, and concentrated by oil-flotation to from 60 to 70% MoS_2 . The concentrates are then converted into ferro-molybdenum, or calcium molybdate, in either of which forms the metal is readily introduced into the steel.

The Climax Molybdenum Co. is the largest producer of molybdenum in the world and is in a position to supply the trade with any commercial quantities over any period of time desired. Climax ferro-molybdenum is produced in two grades, both containing 50 to 60% metallic molybdenum, the 'Regular' grade is guaranteed to contain a maximum of 2% carbon and the 'Special' 0.5%. The former, as the name implies, is generally used. Both are characterized by a low percentage of impurities and great uniformity. Climax calcium molybdate contains about 42% metallic molybdenum, the balance being lime. There is no free carbon or sulphur.

COMMERCIAL PARAGRAPHS

The Roessler & Hasslacher Chemical Co. has moved its main office to more commodious quarters at 709-717 Sixth Ave. The company's postoffice box number will be 119 Times Square Station, New York City.

The Chicago Pneumatic Tool Co. announces that the address of its general offices will hereafter be Chicago Pneumatic building, 6 East 44th street, New York. The company maintains branches at 26 of the larger cities throughout the United States.

The Denver Fire Clay Co. has issued bulletin No. 201 dealing with the company's crushing and pulverizing devices. The equipment which the company lists includes bucking-boards and mullers, grinders, samplers, mortars, and sieves. The bulletin will be mailed on request; either the Salt Lake City or Denver branches being supplied with a stock.

At the annual meeting of Midwest Forge & Steel Co., of East St. Louis, the following new officers were elected: J. W. Eschenbrenner, president and treasurer; C. T. Coates, vice-president and general manager; E. A. Eschenbrenner, secretary. The company was established in 1885, and for the past five years has been specializing in cement-mill and mine forgings, particularly grinding-plates and steel-balls.

The Jackson Compressor Co., of Denver, has issued Bulletin No. 3, describing its high-speed rotary air-compressors. The company is convinced that the rotary machine is the ideal compressor. The principal advantages are a saving

of 75% in floor space and weight as compared with the reciprocating machine; reduction in power resulting from a minimum of moving parts; and the use of the highest type of anti-friction bearings. These features are all emphasized in the machines of greater capacity. The bulletin is available to those interested.

'Smooth-On Home Repairs' is the title of a valuable booklet just published by the Smooth-On Manufacturing Co. In this book has been explained just how to repair leaks in boilers, stove-pipes, radiators, furnaces, tanks, and the many other household fixtures that need attention from time to time. There are from 30 to 40 different kinds of repairs with the remedy illustrated and explained. The use of Smooth-On in automobile repairs receives attention also in this book. Cracked water-jackets, leaky radiators, and scored cylinders are all taken up and their repairs explained.

The A. Lietz Co., 61 Post St., San Francisco, manufacturers of surveying instruments and dealers in field equipment for the engineer, are rendering a commendable service in aiding unemployed members of the profession to find positions. Many of the large corporations are availing themselves of this service by calling upon this company for field help. Transit-men, plane-table operators, draftsmen, and also rodmen and chain-men can be secured through them most advantageously and quickly. No charge or fee is exacted for this service, it being the aim of the company to establish a spirit of good-will among those benefited.

The Barber-Greene Co. manufacturer of belt-conveyors and self-feeding bucket-loaders and other equipment for handling material, announces the following organization of its sales force. R. E. Foulke, 404 3rd National Bank Bldg., St. Louis; J. A. Gurney, 605-606 Arrott Bldg., Pittsburgh; F. S. Sawyer, 1910 Penn Square Bldg., Philadelphia; and W. T. MacDonald, 305 Merchants Bank Bldg., Indianapolis. These are direct Barber-Greene branches and the representatives are experienced engineers, well qualified to furnish the best service and engineering advice to individuals and firms having material-handling problems.

The Oxweld Acetylene Co., of Newark and Chicago, has recently extended its manufacture of oxy-acetylene apparatus and equipment to include 'Eveready' welding and cutting outfits. This is a new name in the oxy-acetylene field, but the apparatus is not new, excepting for certain refinements of design. It has been used extensively in the metal-working trades for several years under the name of 'Prest-O-Lite' apparatus. The new name was adopted by the Oxweld company to suggest the ready convenience, adaptability, and general-purpose uses of the equipment. The apparatus is designed to use exclusively with compressed acetylene in cylinders, thus providing the welder and cutter in a compact and complete portable outfit.

The Wheeler Condenser & Engineering Co. announces the publication of the 1920 edition of its popular booklet 'Steam Tables for Condenser Work'. This is the fifth edition. Every engineer who deals with the condensation or evaporation of steam should have one of these handy tables. The pressures below atmosphere have been especially calculated for this book. It gives the properties of saturated steam from 29.8 in. vacuum to atmospheric pressure in increments of tenths of an inch. The vacuum in inches of mercury is referred to a 30-in. barometer. This method is of course superior to the old method of giving absolute pressure in pounds per square inch, since it is customary to read vacuum in inches of mercury. A complete table is also given of the properties of saturated steam above atmospheric pressure. The book tells how to make measurements by means of the mercury column and barometer. It gives constants and tables for making corrections. It is a handy book and of such size that it can be carried around in the vest pocket.

T. A. RICKARD, - - - Editor

IT is announced that the Scott patents, more particularly No. 1,246,665, have been acquired by the Minerals Separation North American Corporation. These patents cover the use of oil-vapor in the concentration of ores by flotation. We published the text of the principal patent in our issue of December 22, 1917. The patentee, Mr. Walter A. Scott, was formerly a member of the firm of Sheridan, Jones, Sheridan & Smith, of Chicago, counsel for defendants in the several flotation lawsuits; he retired from the firm about two years ago. Since then Mr. Thomas F. Sheridan has been chief counsel. Rights to the use of the Scott patents were secured by the Jackling copper companies three years ago, so that this deal with Minerals Separation will not affect these companies.

VARIOUS bills affecting the mining industry are now before Congress. The Senate Committee on Finance has reported favorably on the zinc and tungsten tariff bills, but it remains improbable that this special legislation will be enacted. A tariff of \$9 per unit for three years is proposed on tungsten ores and concentrates imported into this country. On high-speed tool-steel and other alloys containing tungsten a duty of 35% ad valorem is proposed. Mr. Louis T. McFadden, of Pennsylvania, has introduced a bill, suggested by the American Bankers Association, "for protecting the gold reserve of the United States from industrial depletion" by imposing an excise duty of \$10 per ounce on the sale of all articles containing gold and on all gold used for other than monetary purposes, thereby creating a fund from which the producer is to receive \$10 for every newly-produced ounce of gold. Jewelers and other consumers may still buy gold at \$20.67 per ounce, the tax being, not upon the bullion, but upon the manufactured article.

INSCRUTABLE indeed are the ways of legislators. Witness the case of H. R. 12,976, entitled, "A Bill, to increase the revenue of the Government of the United States and to conserve the supply of print and other paper by imposing a tax on advertisers", introduced by one Mr. Thompson and referred to the Ways and Means Committee. This bill proposes to accomplish these praiseworthy objects by the imposition of a 10% ad valorem tax on advertising in periodicals having a circulation of 5000 or more, and 15% for other advertising. Of course, there is the usual exception in favor of farmers and their implements, without which no present-day piece of legisla-

tion would be complete. How simple it is. The Government needs the money, and, in order to obtain money from its citizens, must perforce aid and abet them in all lawful means of earning money in order that they may, in turn, pay it to the Government in the form of taxes. Since, in order that commerce may be profitable, sales must be effected, and, since advertising is generally conceded by intelligent people as being the most prolific producer of sales, Mr. Thompson would "increase the revenue of the Government" by increasing the cost of advertising, thus decreasing its use and thereby, in turn, reduce sales, reduce profits, lower the revenue received from income-taxes, and increase the cost of living. Hurrah for the amateur economist!

STATISTICAL information concerning the stocks of copper on hand in Europe are given by Mr. John D. Ryan, president of the Copper Export Association, an organization formed a little more than a year ago to facilitate and control the selling of copper abroad. According to Mr. Ryan a year ago the European stocks, excluding those of the so-called Central Empires and Russia, aggregated 545 million pounds of new copper and 385 million pounds of copper in scrap. Thus the total stocks were 930 million pounds. The production during the year was 1800 million pounds through refineries in the United States and 450 million pounds through refineries elsewhere. To this must be added 100 million pounds purchased by "producers", meaning selling-agencies presumably, from the surplus held by our Government, and the copper contents of government stocks of scrap in the hands of manufacturers, this amounting to 150 million pounds, so that the grand total of European stocks, world's production, and stocks acquired from our Government, was 3430 million pounds. From this must be deducted an increase in American refinery stocks amounting to 240 million pounds and the estimated stocks of copper metal and scrap in Europe, amounting to 220 million pounds, or a total of 460 million pounds, which leaves an apparent world's consumption of 2970 million pounds. This exceeds the production for any year in the history of the copper industry.

PATENTS and patentees have been discussed in our pages from time to time, partly from the point of view of rewarding genuine invention and partly from

sympathy with those who are victimized by the piratic exploitation of the rights accruing under governmental license. Therefore we have read an account of the new British Patents Act with some curiosity. In the first place, the law has been changed so that the invalidity of a single claim will not invalidate the whole patent; the infringer can only escape liability by disproving the claim under which he is sued; it is no longer sufficient for the infringer simply to prove the invalidity of any claim. This will help the patentee. Better still, provisions have been introduced whereby a person is enabled without great expense to go before the Comptroller of Patents, an official invested with extensive judicial powers, and obtain from him a compulsory license or a revocation of the patent in cases where the monopoly has been abused by extravagant or unreasonable exactions on the part of the patentee, or if the patent is used to check domestic manufacture to the advantage of importations from abroad. Moreover, a limit of four years is set to an idle patent, if not worked within the country on a commercial scale and no satisfactory reason therefor is forthcoming within the specified period. We obtain this information from an article by Mr. Benj. T. King in the 'Mining World', of London. Mr. King observes very truly that the law is defective in so far as it leans heavily on judicial decisions; nor, may we add, does it provide for the creation of a tribunal specially qualified, by technical education, to adjudicate intelligently. However, we like that idea of a Comptroller, who, like the Commissioner of Patents in Canada, is in a position to discipline a patentee when he is extortionate or unreasonable in his exactions.

A 'CHILE-AMERICAN Association Mining Scholarship' has recently been established by the appropriation of funds sufficient to provide adequately for the traveling and living expenses as well as the tuition of an undergraduate student in mining and metallurgical engineering at the Massachusetts Institute of Technology. The industrial progress of Chile is largely dependent upon the successful development of its mineral resources, which form the greater part of the country's natural wealth. It is estimated that capital aggregating \$150,000,000 has already been invested there by mining interests in the United States and it was with a view to promoting mutual understanding and good feeling that the Chile-American Association was formed. Its membership includes most of the larger American companies doing business in Chile, as well as some individuals who are taking part in the exploitation of the country. While there are a number of mining schools in Chile the opportunity for young graduates to supplement their training with a three-year course in our country will have the dual advantage of affording technical training with a wider scope and an acquaintance with North American customs and ideas that will assist in furthering pleasant and agreeable relations when the young Chilean returns to start his engineering career in his own country. The announced intention is to choose the recipient of the scholarship from among recent graduates of the Chilean

mining schools by means of a competitive examination, the successful competitor to be formally designated by the President of the Republic. It is to be hoped that the selection is actually as well as nominally based on merit; that the youth selected will have, as far as can be predetermined, the qualities of mind and character calculated to make him a successful mining engineer, rather than the political or financial connections that might obtain for him undeserved preferment. The whole plan is a good one and we have no reason to doubt that it will be properly administered.

OUR friend the 'Hyder Alaska Miner' makes this announcement at the top of its editorial page: "A newspaper whose purpose is to tell the world about the newest and busiest town in the Northland, and the native resources which are responsible for its existence." This is frank and to the point; moreover our curiosity is excited by "native" resources. By way of further enlightenment it declares Hyder to be the "gateway to the great Salmon River mineral area at the door of the famous Premier mine", and adds "you *have* to come to Hyder to reach the mines". Apparently the question of route is a matter of Hobson's choice; a disagreeable one, you might infer, with Hyder conceding that it is rather shy on attractions of its own. Nevertheless both the 'Miner' and the Hyder Commercial Association take vigorous exception to what is termed a "libelous interview with a representative of steamship interests", published in a Seattle newspaper. It appears that the gentleman interviewed questioned the ability of Hyder to outfit prospectors; declared that the town was built on piling; doubted its ability to accommodate transient visitors; and reflected upon the character of the drinking-water; all and sundry of which aspersions evoked strenuous protest from the citizens of Hyder, who now answer each indictment in detail. The leading merchant has just finished invoicing a stock of miscellaneous supplies valued at \$23,000. This figure really would have been more impressive five years ago; however, in addition it is pointed out that Prince Rupert is but 24 hours distant by boat, so that further supplies can be obtained readily, if needed to outfit prospectors. As to being built on piles, Hyder pleads guilty to the charge; it makes no apology, but points with pride to Aberdeen and Seattle as glittering examples of success achieved on an underpinning of piles. The answer to number three is the existence of "two large hotels and five rooming-houses, each of the latter being able to accommodate from 12 to 50 roomers". These statistics of hotel capacity are admittedly rather vague; and we venture to advise anyone going that way to provide himself with a substantial bed-roll before leaving Seattle, on the theory that it's better to be safe than sorry. The water must certainly be good, else there would have been a "mortality list ere this". Moreover, the 'Miner' assures us that "there are ten wells in the piled district, all driven into a subterranean stratum and all producing water which is good for anyone who likes water". It is reassuring to know that the stratum

is subterranean, although we feel some concern for the visitor who doesn't care for water. Are there other available liquids besides the products of these excellent wells? We hardly believe that the representative of the shipping interests had any motive in misrepresenting conditions in Hyder or that Hyder will suffer as a result of what he did say. The men who go in search of gold and silver do not expect to find the convenience of Wana-maker's or the comforts of the Waldorf on the fringe of the frontier. Perhaps Hyder disdains gratuitous advice; nevertheless we suggest that it is poor policy to declare as vociferously as Hiram Johnson that the fortune-seekers must go through Hyder, intimating that it is a necessary though disagreeable part of the journey to the mines. If one has a monopoly, why gloat over it? A more tactful scheme would be to point out the pleasant features of a brief sojourn at Hyder; for instance, its splendid site on the bay, its salubrious climate, its inexhaustible supply of pure Alaskan air, and, may we suggest, the excellent accommodations of the commodious Hotel Metropole. Incidentally the 'Miner' advises that the snow will not be melted so as to permit successful prospecting before June 1. Let us go thither then!

Mr. Hoover Will Accept Nomination

Soon after we went to press last week, namely, on March 30, the political situation was clarified, particularly for Mr. Hoover's friends and supporters, by the telegrams sent by him to Messrs. Warren Gregory and Ralph Merritt, both in San Francisco. We reproduce these telegrams on page 549. In the first Mr. Hoover states that he is convinced that it is his duty to confirm the action his Republican friends in California have taken without consulting him. We like particularly the sentence: "The issue is whether, with reservations protecting our position, we should join the moral forces of the world to reduce the dangers again growing around us, or whether we will, *by pretense of an insularity that we do not possess*, sit by in the face of growing armies, navies, national antagonisms, reactions, or, in reverse, the spread of bolshevism, through much of the world." The italics are ours. The Treaty of Peace and the League of Nations are discussed more specifically in the message to Mr. Merritt, which concludes thus: "Two years ago when the entire world was aligned against Germany, our prayer was that we might be fighting the last great war—that something better should come to the world in return for the sacrifice. Today the world is drifting back, and through our failure victory may turn to new antagonisms." Both messages deserve to be read carefully. They show once more that Herbert Hoover is a statesman as well as an engineer. They will appeal to the enlightened spirit of a true Americanism, as distinguished from the sentimental internationalism of President Wilson and the frothy provincialism of Mr. Johnson. Here we may note that sundry irresponsible newspapers have misquoted the New York 'Times' as having endorsed Senator Johnson's candidacy. We read the 'Times' ourselves and were not deceived. In its

issue of Sunday, March 21, it said editorially that "if Mr. Lodge is to be approved and sustained, logic and consistency point inerringly to Hiram Johnson as the man to be nominated by the Republicans". The italics are ours. And it followed this by saying: "It would be a calamity for the country. We should regard with great apprehension the nomination of Senator Johnson." So would many of us. Another perversion of the truth is the assertion by Mr. Jonathan Bourne, Jr., president of the Republican Publicity Association, that a number of newspapers and periodicals of the country have been organized into "a perfectly operating machine" for Mr. Hoover. Mr. Bourne remarks that "the Hoover machine is well constructed and evidently well supplied with fuel and oil and grease". Similar suggestions have been made by Mr. Johnson. It may interest our readers to know that we, for example, have not talked or corresponded with Mr. Hoover since last October, when he had nothing to say about the possibilities of his candidacy for the Presidency. His talk was all about economic conditions in Europe and in this country. We believe that the propaganda of other newspapers and periodicals has been like our own, wholly spontaneous. We know also that his friends in California, who in the end succeeded in getting him to acquiesce in their efforts on his behalf, as a candidate on the Republican ticket, acted entirely on their own initiative and took the risk of being made to appear foolish if Mr. Hoover had finally refused to accede to their importunities. The fact is Mr. Hoover's candidacy is the product of a genuine popular call. The political machines, especially Mr. Johnson's, do not approve of such direct action; they have come to regard themselves as the last word in politics; they resent the ordinary citizen's trespass upon their preserves. The Hoover campaign will show whether the mass of the people can express their desires in opposition to the powers that be. In California Mr. Hoover is opposed by a political machine that has been perfected by a most adroit and experienced politician. It remains to be seen whether the perpetually indignant Mr. Johnson or the great Food Administrator can win the more votes. The issue is clear.

Industrial Relations

The production, in general, of the individual wage-earner today, as compared with that of 1914, has decreased between 15 and 50%, depending upon the particular industry and upon local conditions. This fact is incontrovertible. On the other hand, there is urgent need for increased output of most commodities, and until this increase is an accomplished fact, prices, as far as can be foreseen, will not decline. The seriousness of this economic crisis is being explained to the workers and they are being urged to apply themselves with at least pre-war efficiency to their tasks, with a view to reducing the present level of prices and thereby directly benefiting themselves. However, it is difficult to convince the average wage-worker that such action on his part is really to his advantage, and that such a program offers any

tangible benefit to himself and to his family. He reasons that if production is increased to the normal point where it exceeds consumption there will be an over-supply of labor instead of the present shortage; that jobs will become scarce and that wages will drop, necessarily. There is today a widespread and implicit understanding among laboring men to restrict individual production, thereby maintaining the present level of wages, no matter what may be the effect on commodity prices. This condition of affairs obtains in the mining industry. The problem is to alter the attitude of the miner and to offer him a definite inducement or incentive to work hard. The paper by Mr. Edwin Higgins, appearing in our issue of February 28, outlined in a comprehensive way various measures that should be taken to obtain co-operation and willing effort from the miner. Attention to sanitation, safety and first-aid, the improvement of working conditions, various social-service and welfare activities, and the practice of the square deal all are variously contributory to efficient operation. The progressive manager, however, has realized the mutual benefit of adopting these ideas and has made headway, in some degree, toward putting them into effect. There remains, as the main issue between the employer and the employee, the question of financial remuneration, whether in the form of wages or otherwise, for service performed. The principle of the square deal must be made to apply to the miner's pay as well as to other relations; confidence in the financial honesty of the company must become rooted in the employees, so as to assure them of fair treatment as long as the business thrives; and a system of payment must be devised that will recognize competence and diligence. The average miner really believes that the wealthy owners of the mine are pocketing enormous profits, that this is entirely unearned, and that it represents the exploitation of the wage-earner, who himself has to forego all the good things of life. It has been suggested that the public posting of a company's operating accounts each month would promote confidence and good-will even though some of the miners might not understand the meaning of all the figures given. Certain large mining companies that had been paying really excessive dividends during the War immediately cut the wages of their men when the price of metals fell early in 1919; although the war wages were no more than enough to provide a mere livelihood for the head of a family and the cost of living showed no prospects of decrease. The fact that some of the companies returned to the former scale after a brief interval indicates that possibly they themselves concluded that the cut had been ill advised. However, from the point of view of the laboring man, such arbitrary action suggested an utter disregard for his welfare, and seemed to support the idea that distribution of dividends was the paramount consideration of the employer. Such inconsiderateness may account to some extent for the present antagonistic attitude of the wage-earners, many of whom sincerely, though mistakenly, think that they are doing the best thing for themselves by restricting output. It will require time and it will need the continued use of the square deal on the part of managers

everywhere to inspire the necessary confidence in the broad-gauge honesty of employers. There remains one important influence that can have an immediate good effect on the efficiency of operation: If a miner knows that the harder he works the more money he will receive on pay-day, he is strongly inclined to put forth his best effort.

Schemes for paying miners may be grouped under four heads, namely, (1) day's pay, (2) contract or piece work, (3) task and bonus, and (4) co-operative bonus. The only way to get reasonable efficiency by the straight day's pay method is to make the scale of wages in a given district sufficiently high to attract a surplus of first-class men; a miner will then do an average day's work in order to avoid being discharged; but there is little inducement to extra effort. Moreover, the scheme is unscientific, in that it makes no provision for extra pay for exceptional service. In the second plan, payment is based on cubic volume of rock broken, the number of feet advanced, the number of cars trammed, or some other unit. This method is in disrepute because of the former practice, particularly in shop-work, where the piece system originated, of cutting rates when workmen became expert. This was obviously bad faith on the part of the employer. Nevertheless the contract system has the merit of paying each man in proportion to what he accomplishes, and if honestly and fairly administered has advantages that more than offset its shortcomings. In our last issue there was an article by Mr. A. K. Kniekerbocker in which he discusses the contract system as applied in the Minnesota iron mines. He reveals his close contact with the miners, and a sympathetic study of their point of view, no less than a clear comprehension of the problem as it appears to the mine manager. The 'task and bonus' plan is a refinement of the contract scheme, and at the same time has distinctive features of its own. A standard time-equivalent for each detail of work is first determined and a complete record of the performance of each miner is kept. The required task may be set at any percentage of the standard and the bonus is based on any accomplishment over and above the task. Every man in the mine can be included. The co-operative bonus plan distributes to every employee who works a specified number of days an equal share of a sum determined from the net result of all operations over a period of a month. It has the merit of encouraging co-operation to a maximum degree; but it makes no distinction between the good man and the extra good one. While it has notable successes to its credit in other industries, it is objectionable as being a kind of profit-sharing scheme; and it is not easily applied to mining operations. There are today many individual plants operating at maximum efficiency, in the midst of an immense majority where the production per man has notably decreased. They are doing this because they pay their men well and scientifically; because their employees are reasonably certain of something more than a 'living' wage so long as the particular industry flourishes; and because there is a spirit of mutual trust and fairness between employer and employee.

DISCUSSION

The Combination Method of Mine Sampling

The Editor:

Sir—Mr. Morton Webber's article in your issue of February 28, on this subject, is especially valuable and interesting at this time, owing to the revival of silver mining. Anyone who engages in the sampling of silver mines soon learns that the true average grade of the ore in a large proportion of these mines cannot be accurately determined by hand sampling alone. It is necessary in many cases, to supplement the hand sampling by some other method, and the 'combination' method described by Mr. Webber should give satisfactory results in nearly every instance.

I would suggest, however, that the misleading term, mill-test, should be discarded in favor of a more accurate term, such as 'bulk-sampling', because this method is in no sense a mill or metallurgical test but is for the sole purpose of determining the gross grade of the ore or rock sampled. It is usually necessary to have metallurgical tests made in addition to any method of sampling. The result of the bulk-sampling can also be more satisfactorily and accurately obtained, as Mr. Webber states, by means of a bulk-sample rather than by milling.

San Francisco, March 22.

FRED H. DAKIN.

The Metallurgy of Complex Low-Grade Ores

The Editor:

Sir—Bulletin No. 9, issued by the Utah Engineering Experiment Station of the U. S. Bureau of Mines at Salt Lake City, states, on page 28, in part:

"Sulphurous acid leaching of copper from its ores is technically feasible and the department in conjunction with its co-workers has tested out a number of pieces of machinery in order to dispose of the mechanical difficulties which have previously interfered with the successful application of the method."

Dr. F. C. Cottrell, having in mind the 2000-odd tons of sulphuric acid gas that are being daily wasted at various establishments recently prophesied while at Butte that "the future advances in science would largely be concerned with gases".

These statements are practically the "first official guns" to announce the new metallurgy, namely, hydrometallurgy in a form embodying more chemical and metallurgical correctness of application than heretofore was thought possible of application.

Leaching with sulphuric acid presents nothing new,

as in some modification or other it has been practised for a great many years, and in reviewing its method of manufacture and application to ores in general, one can not but realize the cumbersome nature of the solvent itself, likewise its application. For example, ordinary commercial sulphuric acid may contain about 50% of water, and this water in the chamber process of making the acid is necessarily present, hence it presents costs in terms of the strength of the acid produced. In shipping the acid, containers have to be provided to hold both the acid and the water; the railroad and hauling charges have to be paid for on the water in terms of acid. Elimination of a great part of the water can be effected by concentrating the acid, but the purchaser will generally find the price advanced beyond the economy obtained over the purchase price of the commercial article.

Absolutely pure sulphuric acid contains 18.41% of water as a matter of chemical necessity in its make-up, so that it becomes obvious that "some water" must be taken by anyone using sulphuric acid; besides, the strongest acid that can be readily handled is but 97% pure, containing 3% impurities, mostly water, in addition to that mentioned above.

The erection of a plant to manufacture oil of vitriol is not a poor man's opportunity. The construction of an Eastern company for its 500-ton acid plant was \$1,689,925. That of a Western mining company with a normal capacity of 100 tons acid per 24 hours was \$470,000. The above installations, however, have been forced much beyond their normal capacity. The plant deterioration has likewise been found to be excessive.

Previous to the construction of the Western plant, Denver or Coast points furnished the acid and the transportation and hauling was no mean portion of the total cost. The acid-makers have been quite fortunate in the matter of payment of dividends, so that the apparent cheapness of sulphuric acid may not be cheapness at all when the original cost of production is given due consideration.

The primary step in fabricating oil of vitriol is burning sulphur, either in a metalloidal state, or combined as a sulphide to form sulphur di-oxide gas. This step is simplicity itself, sulphur readily igniting and burning to sulphur di-oxide gas practically alone. Nature wisely provided that sulphur could not directly be oxidized to sulphur tri-oxide and then by union with moisture become sulphuric acid, otherwise the roasting of sulphide ores would be almost impossible.

This provision of nature, however, has its drawback, inasmuch as an expensive plant is necessary to carry on

the oxidation of sulphur di-oxide gas to sulphuric acid. Here engineers failed to recognize, and, figuratively speaking, cast aside and made an enemy of the simple and effective natural acid that nature was making for them, choosing, as it were, the most difficult and expensive way of overcoming a difficulty which the new line of thought, embodying the utilization of waste sulphurous gases in the recovery of various metals and by-products, as applied in the sulphur di-oxide process. It has been experimentally proved to be highly successful in the treatment of complex low-grade ores of zinc, lead, silver, manganese, tungsten, and the like, that are to be found in great abundance here in Nevada, and thus far not utilized.

Reno, Nevada, March 19.

Chloridizing Processes

The Editor:

Sir—I have read Mr. Croasdale's pleasant communication and some of those referred to in your issue of February 21, and I am still of the opinion that he did not recognize the importance of rapid heating in chloridizing volatilization processes that were not dependent upon reactions in which sulphur was to be considered.

It appears that Mr. Croasdale's latter proposal, to feed the furnaces with a small stream of ore, was for the purpose of causing the ore to be more rapidly and thoroughly exposed to the oxidizing atmosphere of the furnace, and to provide a thinner bed through which the volatile chlorides could escape more easily than would be the case with the thicker bed. Mr. Croasdale's writings show that his predominating ideas on the necessary conditions for chloridizing volatilization are that sulphur must be present and that the particles of ore must be thoroughly exposed to an oxidizing atmosphere by means of continuous rabbling or rolling of the ore. He claims that rapid volatilization depends upon rapid oxidation, which is accomplished by rapid rabbling or rolling of the ore. In order to realize Mr. Croasdale's reactions, it was probably necessary to expose the ore thoroughly to an oxidizing atmosphere, but this could probably be better accomplished by means of small or rather thin streams of ore and frequent rabbling. His reference to the fact that the operation must be done quickly in order to make it commercial is not made in the sense that I intended to convey in my article and does not consider rapid heating in the same sense as I considered it. It is obvious that if an operation required so much time as to cause great expense such an operation would not be likely to prove a commercial success.

I have found that where the metals are so exposed or so combined as to be easily chloridized their chlorides are volatilized practically as rapidly as they can be brought to the proper temperature and that the chloridation and commercial volatilization are effected in such cases of easily chloridized ores within a very few minutes—less than ten minutes in some cases—after the ore had been brought to the proper temperature. I have not found it

necessary to rabble or expose the particles of ore to oxidizing atmospheres when using some of my methods on oxidized or carbonate ores.

In my original article, I failed to mention that slow heating in the case of some ores caused the chloridizing agent to be decomposed and the chlorine completely driven from the ore in less than fifteen minutes from the time the cold ore was charged into the furnace and that the chlorine was driven from the ore without any appreciable extraction of silver. In one of these cases, over 15% chloridizing agent was added to the ore. A long revolving furnace fired at the discharge end certainly would not be suitable for such an ore. I have lately been working on a lead-silver ore that yields as good if not better extractions of the silver under reducing conditions than those which could be obtained under oxidizing conditions.

HARAI R. LAYNG.

San Francisco, March 4.

OSMIRIDIUM deposits in Papua have been known for many years. It occurs in association with gold, and in the beginning it was treated as base metal and thrown away, just as it used to be in Tasmania, where the prospectors looked upon it as a nuisance. Those miners in Papua who sent it to the banks, or the mint, with their gold, found that it was accounted base metal, and upon discovering that it was of much greater value than gold, believed that they were receiving unfair treatment; but the mints, on the other hand, complain that the presence of osmiridium with the gold is a serious trouble, as unless they are quite separated, the particles of osmiridium in the melted gold have the effect of defacing the dies used in coining. There are considerable quantities of serpentine in Papua, and it is notable that in the districts where this abounds osmiridium occurs in association with only small quantities of gold. It has so far been recovered only by gold diggers as a by-product, but the best deposits will not be found until it is made the principal object of search. It occurs in a flaky form in the Lakekamu district; in a form not unlike native bismuth in the Yodda valley; and elsewhere in shot-like granules.

TIN, in spite of the unsettled state of the metal market, appears to be able to hold its own. The needs of the War did not force its increased production, as was the case with copper and lead, for instance, and consequently at the cessation of hostilities no large stocks were on hand. In fact, in spite of the extremely high price it reached during the late stages of the War, the output has decreased; this was especially the case in Australia. During the period of scarcity of tin-plates and very high prices for them and for tin, attempts were made to find substitutes. Some were successful up to a certain point, but they cannot compete when steel and tin are at normal rates. The average price of tin for the month of September 1918 was £344 per ton, but after the Armistice it fell, until February 1919 the average price was £223. Since that date there has been a steady increase.

The Present Mill and Its Operations

By T. A. RICKARD

The ore coming out of the mine through the Kellogg adit is delivered by electric trains into a storage bin of 1400 tons capacity. From the bin it passes through open chutes onto a 42-in. belt-conveyor, the speed of which varies from 17 to 55 ft. per minute, as regulated by a Reeves variable-speed drive. The essential feature of this device is a double cone supporting a belt mounted on wooden blocks cut to the taper of the cone that gives the friction to the drive. The interval between the cones, and the consequent diameter, is increased or decreased by a sprocket control.

The mine-run of ore carried by the belt-conveyor passes under a 36-in. electro-magnet, which removes hammers-

heads and other pieces of steel, then the ore falls over a grizzly having 1½ in. openings and into two No. 5 bronze ball crushers, the discharge from which joins the undersize from the grizzly and is conveyed on a belt to three trommels of 30 mm. screen. The undersize from the trommels passes to a storage bin, while the oversize is removed to a 36-in. Symons vertical disc crusher, set to ¼ inch, or 20 mm. The discharge from the crusher is conveyed to one 30-mm. trommel, the undersize from which goes to the storage bin, while the oversize joins the discharge from the crushers, in closed circuit. This completes the crushing operations. See Fig. 7. Next comes the coarse concentrating and grinding. From the stor-

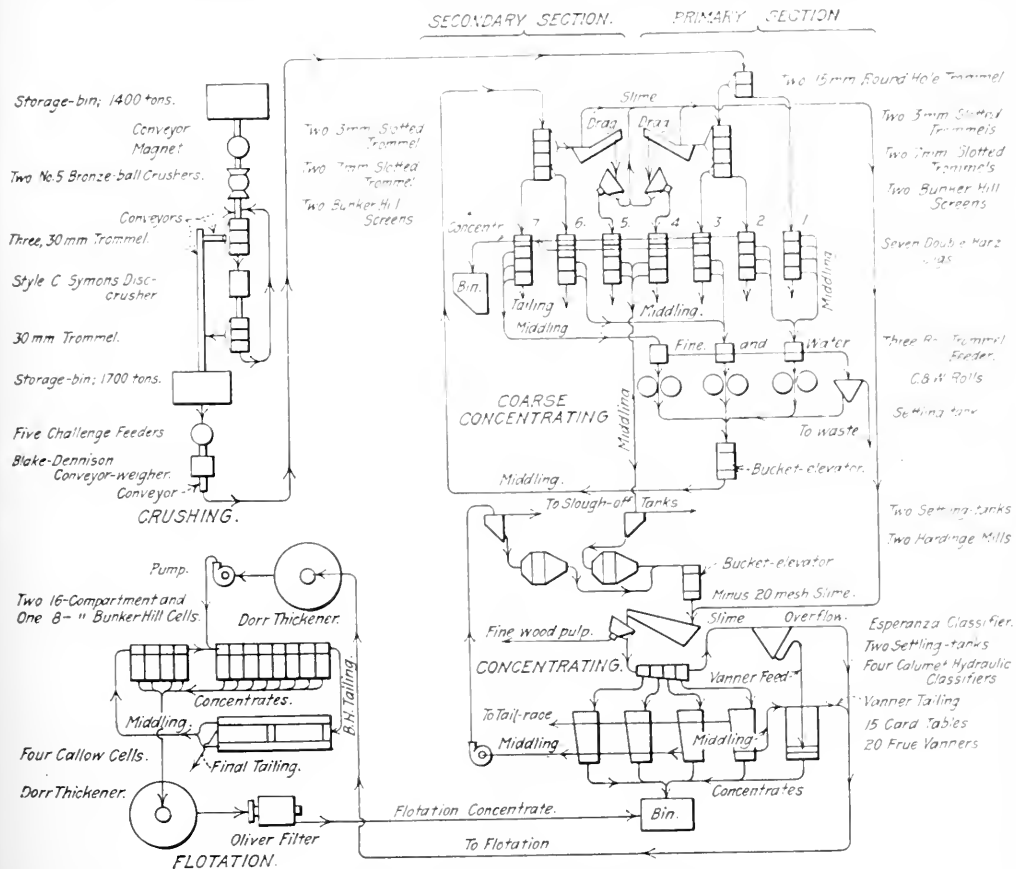

Fig. 7. FLOW-SHEET OF WEST MILL NO. 2

crushed ore is fed by five belt-driven Challenge feeders on a conveyor inclined at an angle of 22°-30°. The belt-conveyors give a remarkably uniform supply and require the minimum of attention, as the 1/2 inch wear plates on the revolving disc will last for a year. The rollers are driven from the tail pulley of the conveyor. A third of the way up the conveyor incline the stream of ore passes over a Blake-Dennison weighing machine, made at Leeds, England. The accuracy of the weighing is indicated by the fact that the error is less than 0.5%. It should not be necessary to emphasize the importance of an accurate weighing and an equally accurate assay of the ore, in order to know at all times the quality and quantity, that is, the metal contents and tonnage, of the mill feed, for this constitutes the basis upon which the entire economic result is predicated.

The belt conveyor discharges into a revolving distributor of the vertical barrel type, so as to divide the stream of ore equally between the two sections of the mill. From this point one section only will be described, the other half being now a duplicate, although originally it was different.

From the distributor the crushed ore falls into two 15 mm. round hole trommels (48 in. diam. and 60 in. long), the oversize from which passes to three four-compartment Harz jigs, while the undersize goes to two 48 in. trommels divided into four sections, each section being 30 in. long, three of 3 mm. by 6 mm. slot screens, and one section of 7 mm. by 1/2 in. slots. These slots are aligned with the circumference and give a more effective clearance, which means a larger capacity. The oversize from the 7-mm. section goes to two four-compartment Harz jigs, and the undersize to one jig of the same kind. The undersize from the 3 mm. section of the trommel passes to a 6-in. belt drag classifier, which separates the slime as an overflow that goes to the fine-concentration department, while the sand is delivered to two Bunker Hill screens equipped with 22 mesh Ton-Cap screening. The oversize from these goes to two jigs, similar to the above, while the undersize joins the overflow from the drags and passes forward to the fine-concentration department.

Turning to the jigs: these are built at the mill after designs by Mr. Caetani. Each cup is placed in the centre of the end of each compartment, instead of being in the centre of the side. Experience has shown that whereas this arrangement equalizes the draft from the bed, it complicates repairs by making it necessary to remove the discharge pipe frequently; and this is a difficult operation because the pipe becomes so wedged by fine sand as to require the use of a chain-block to remove it.

The No. 1 jigs, treating the material between 15 mm. and 30 mm., do not yield any concentrate of shipping grade; they produce a large tonnage of low-grade (0.4 to 0.5% lead) tailing, which goes to waste, and a middling consisting of mixed lead and siderite, as well as particles of clean galena, the product assaying 18 to 25% lead. This goes to the coarse rolls. From the No. 2 jigs, treating material between 7 and 15 mm. size, the first cup yields a finished concentrate assaying 65%; three cups yield a middling, assaying 10 to 13% lead which

normally goes to the intermediate rolls, but occasionally the product from the second cup is diverted for the use of the smelter, as flux, on account of its high iron content. These jigs discharge a tailing, containing 0.7 to 1.0% lead.

The No. 3 jigs, treating material between 3 and 7 mm., yield from the first cup a finished concentrate assaying 75%, a finished product from the second cup assaying 65%, and from two cups a middling assaying about 7 to 10% lead. The third cup is periodically diverted to the smelter, for flux, as stated above. The tailings from these jigs assay 1 to 1.2% lead and are sent over the dump.

The No. 4 jigs, treating material between 3 mm. and 20 mesh, give a finished (77%) product from the first cup, another similar 70% product from the second cup, and a middling (assaying 8 to 10%) from the third and fourth cups. This middling normally goes to the rolls, but, as before, it may be diverted periodically direct to the smelter. The last cup discharges a silicious product, made in order to produce a clean tailing, and is therefore not wanted by the smelter. The tailings from these jigs assay 1.3 to 1.5% lead and go to waste. The hatch products are included in the cup products from most of the jigs and do not call for separate description, being of about the same grade.

The middlings from the No. 1 and No. 2 jigs pass to a set of coarse rolls, 36 by 14 in., made by Chalmers & Williams, while the middlings from the No. 3 and No. 6 jigs go to the intermediate rolls, of the same size and make. The middlings from the No. 4 and No. 5 jigs pass to the fine-concentration department. The discharge from each of these sets of rolls is raised by a 16-in. bucket-elevator to the middling section of the mill, which is an exact duplicate of that which treats the original feed from 15 mm. size down. The products from the No. 6 jigs in this secondary section go to the rolls, there joining the primary middlings. The middlings from the No. 7 jigs pass to another, or third, set of rolls of similar size and make.

Each set of rolls is provided with a trommel-feeder, consisting of one section 30 in. long and 24 in. diameter of punched steel-plate having 3-mm. holes. This feeder distributes the millstuff uniformly over the face of the rolls, and at the same time removes the excess of water, which is settled in a V-tank. The overflow from this tank goes to waste; the discharge from the spigot of the tank serves to wash the discharge from the rolls into the elevator already mentioned. This arrangement serves to provide a constant volume of water for the slime through the sizing system of the secondary section. The thickened pulp from the V-tank feeds twenty-one 6-ft. Frue vanners, which make a finished concentrate (assaying 67%) and a tailing (61%) that goes to the flotation plant. This tailing joins the dirty overflow from the V-tank.

Next we come to the fine-concentration department. The middlings from the No. 4 and No. 5 jigs go to a settling-tank, the overflowing clear water from which goes to waste, while the spigot discharge feeds a Hardinge

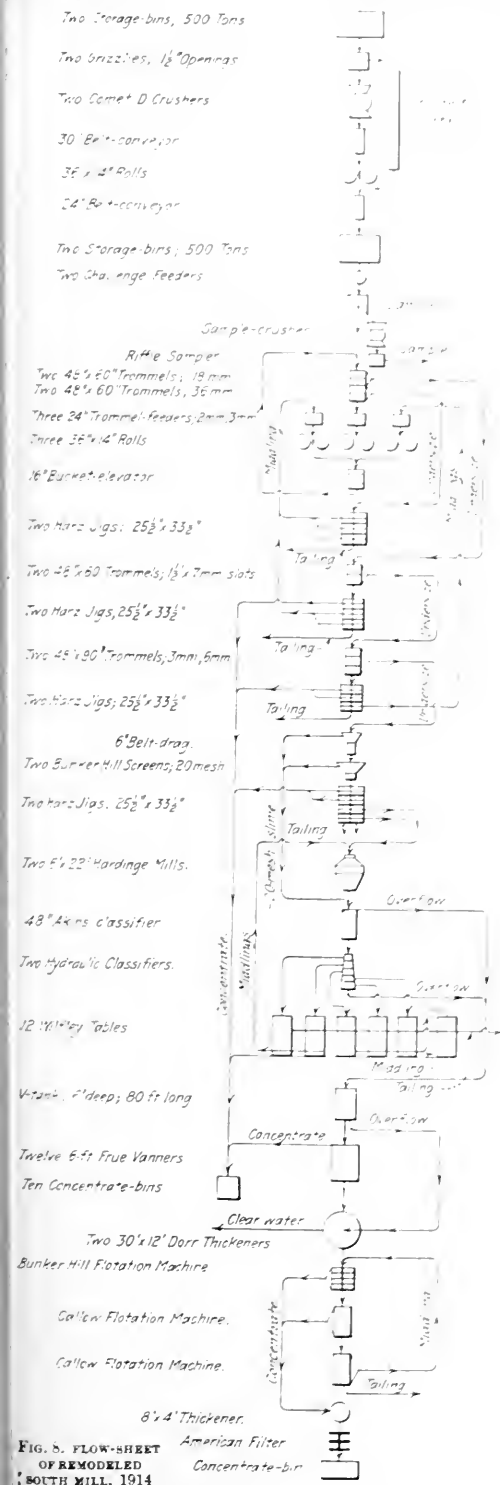

FIG. 8. FLOW-SHEET OF REMODELED SOUTH MILL, 1914

pebble mill 6' x 22' in., by which it is reduced to minus 20 mesh. From there it goes to a 16-in. bucket-elevator, the discharge from which joins the minus 20-mesh products from the primary and secondary sections of the jig floor. United these pass to an Esperanza (5 by 17 ft.) classifier which separates the bulk of the slime (minus 200-mesh) from the sand. The slime is transferred to a V-shaped tank which thickens the pulp (10:1, water:solid) for the vanners. The sand goes to three Calumet hydraulic classifiers, of five spigots each, which prepare it for treatment on the Card and Deister tables.

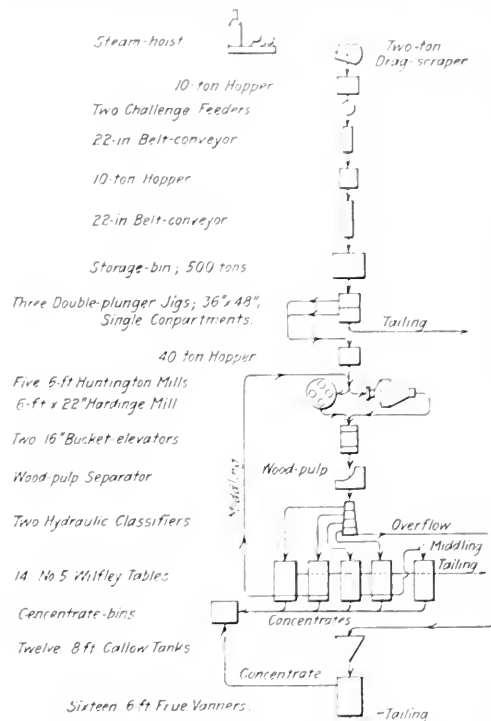

FIG. 9. FLOW-SHEET OF NORTH MILL WHEN TREATING SOUTH MILL TAILING-DUMP, 1911-1913

These classifiers are equipped with cast-iron sorting-columns, as designed by the Bunker Hill staff. Between the Esperanza and the Calumet classifiers the removal of any wood-pulp is effected by the use of a Bunker Hill screen.

The tables are distributed thus: five tables to the first spigot, four to the second, three to the third, two to the fourth, two to the fifth spigot, and two for re-treatment of fine-table middlings. In this section all the 18 tables are Cards; in the other section there are 16 Cards and two Deisters (one 'Plateau' and one 'Plato'). Experience in this mill, says Mr. Handy, shows that the riffing is the determining factor, rather than the head-motion or any other detail of construction. The best riffing appears to be that on Plato table.

All the tables discharge a finished concentrate averag-

ing 72 to 74% lead, and a middling that in the case of the coarse (first and second spigots) tables is returned to a Hardinge pebble-mill (6 ft. by 22 in.) for re-grinding. The middlings from the fine tables (third, fourth, and fifth spigots) are returned over two middling-tables, making a concentrate, a middling that goes to the flotation plant, and a tailing that goes to waste. The tailings from the coarse tables assay 1.75 to 2% and go to waste; the tailings from the fine tables assay 1.5% and likewise go to waste.

The flotation department starts with a Dorr thickener (40 by 12 ft.), which dewateres the pulp to a 1:1 consistency. This pulp (at the rate of 95 dry tons per 24 hours) is delivered to two 16-cell Bunker Hill flotation machines, in which mechanical agitation is effected by eight 1½-in. centrifugal pumps in each machine. These use 1½ hp. per pump. The product is a concentrate assaying 60 to 65% lead; the tailing, assaying 3½ to 4%, is pumped to two sets of Callow standard double cells in series, the froth from which assays 30% lead; this froth is brought up to 45% in a Bunker Hill 8-cell cleaner, while the tailing (1%) goes to waste. The tailing from the cleaner is returned to the feed and dilutes it to a consistency of 3:1. The concentrate goes to a Dorr thickener (40 by 12 ft.), where its consistency is reduced to 35% moisture by an automatic intermittent discharge, regulated by an oscillating gate, operated by an eccentric and placed over the spigot. This passes to an Oliver filter (8 by 6 ft.), which reduces the moisture to 11%. On this filter the film of oil on the cake is removed by a 'flapper', consisting of rawhide strips, on a revolving wooden shaft, that impinge on the cake.

Only pine-oil is used; one gallon per day or 0.08 lb. per dry ton. I noted an absence of the aromatic odor usual in flotation plants.

Mazda C lights are used throughout the mill; they give a daylight effect, which is the reason why they were adopted first by silk salesmen.

Next we come to the remodeling of the Old South mill as adapted to the treatment of ore from the Sierra Nevada and Caledonia mines. See Fig. 8. As far as the head of the sizing system, the old flow-sheet (Fig. 3) was retained, the first noteworthy change being the substitution of slotted screens on the 7-mm. and 3-mm. trommels and the discarding of the 10-mm. trommel. The jigs were standardized with those in the West mill, except that the discharge was placed at the side instead of being in the center of the end of the compartment. The undersize of the 3-mm. trommel was made to follow the same route as in the West mill No. 2 (See Fig. 7). The rolls were made standard (36 by 14 in.) with the West mill. The standardization of the trommels, drags, fine screens, jigs, rolls, elevators, and classifiers is an important factor in the economy of the various Bunker Hill plants.

Another feature of this remodeled Old South mill is the use of two belt-driven Hardinge pebble-mills (6 ft. by 22 in.) and the use of a 48-in. special Akins classifier, instead of the Esperanza machine. The flow-sheet of the flotation annex is identical in essential details with that

in the West No. 2 mill, except for its smaller scale.

Finally we come to the flow-sheet of the North mill after it had been remodeled, in 1911, for re-treating the tailing of the South mill dump. See Fig. 9. This tailing was excavated by a two-ton open-bottom drag operated by a double-drum steam hoisting-engine of 60 hp., delivering into a 10-ton hopper, from which it was fed by two belt-driven Challenge feeders to a 22-in. flat-belt conveyor, 600 ft. long. This delivered to a hopper feeding a 22-in. trough-belt conveyor set at 22° and discharging over a grizzly into a bin of 500 tons capacity. From this bin the tailing was washed through a chute into three double-plunger bull jigs of the Harz type, with a single (36 by 48 in.) compartment, provided with two gate-discharges. These jigs yielded a middling that assayed 6% and was delivered through a storage-bin to five 6-ft. Huntington mills and one Hardinge pebble-mill (6 ft. by 22 in.). The pulp from these mills passed through 20-mesh screens into two 16-in. bucket-elevators, which delivered it, through two stationary wood-pulp separators, to two hydraulic classifiers. The spigots of these classifiers fed 14 No. 5 Wilfley tables, while the overflow passed to twelve 8-ft. Callow tanks, the thickened discharge therefrom passing to sixteen 6-ft. Frue vanners. The products from the tables were a 35% concentrate, a 5% middling that was returned to the grinding machines, and a tailing (3%) that went to waste. The jig-tailings assayed 1% lead. This mill was operated during the summers of 1911, 1912, and 1913, treating 300,000 tons of tailing during this time.

In comparing the flow-sheets of the No. 1 and No. 2 West mills, it will be seen that in the first the controlling idea was to simplify the sizing system, which consisted of one set of 10-mm. trommels, and to finish the sizing in the jigs. The undersize from these trommels passed to classifying jigs, which, in addition to concentrating the sand, also separated a slime product. This entailed an excessive proportion of hutch product, which was so low-grade that it had to be re-concentrated. The tailing, of course, was high on account of the variable size of the material fed to the jigs. Meanwhile the concentrate (assaying 45%) from the coarse jigs was ground in Huntington mills, the discharge from which was treated in hydraulic classifiers and fed to nine Card tables, yielding a 77% concentrate, a second concentrate of 60%, a middling of 15% that went to the grinding system, and a 7% tailing that went to waste. This, although it seems bad technically, was justified commercially by the saving in freight and treatment accomplished by keeping waste out of the high-grade concentrate that was shipped to the smelter.

In the No. 2 plant, the advantage of sizing is fully recognized, because a lower tailing and a higher concentrate can be made on a sized product, as against an unsized. Another point, on which Mr. Handy places emphasis, is that in making a low-grade concentrate only on the coarse jigs, a cleaner tailing is possible, the first concentrate being then crushed and re-jigged so as to produce a 65% product, as against the 53% product ob-

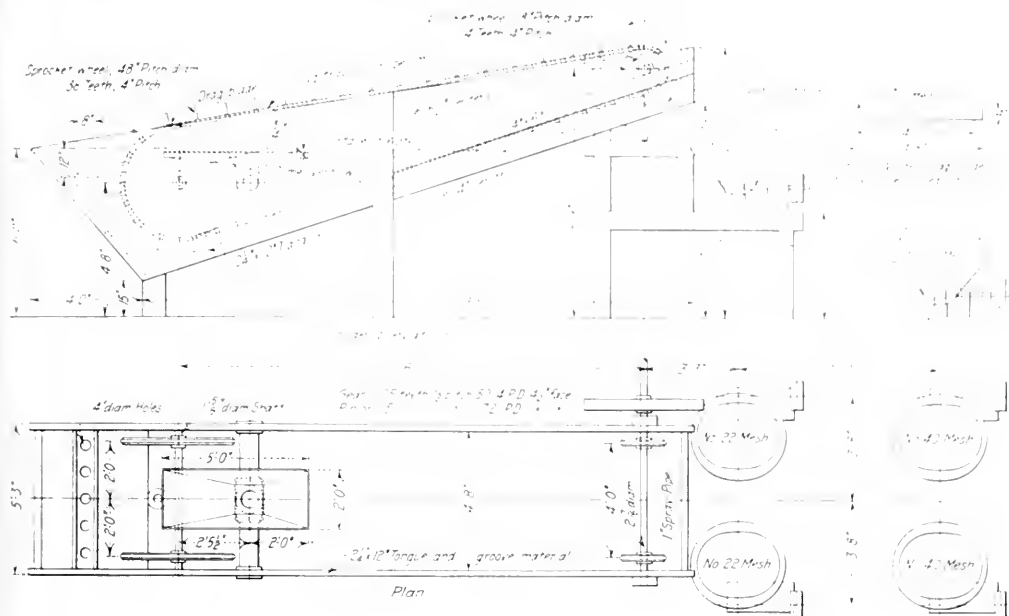

FIG. 10. ESPERANZA CLASSIFIER

tained by the first jigging. This is due to a reduction in the size of the feed by passing it previously through the rolls.

It is interesting to note that the average monthly production of 77% concentrate in 1911 was 362 tons in the No. 1 section of the West mill, while the production of second-class concentrate was 719 tons and of slime 922 tons. This was the result of grinding the 45% product in the Huntington mills followed by re-concentration on tables. In August 1912, when the gradual reduction by rolls followed by re-jigging of the bull-jig concentrate had been established in the No. 2 section, the production of first-class (or 77%) had risen to 1010 tons, of second-class to 2616 tons, and of slime to 1183 tons monthly. Assuming that the No. 1 section was still working at the normal rate, this would give the production of the No. 2 section as 648 tons of first-class, 1897 tons of second-class, and 261 tons of slime. The 7% tailing that had been discarded in the grading was included automatically in the grinding system and went out with the regular table-tailings at probably not over 3% lead. In changing the

grinding practice from Huntington mills to rolls there were eliminated 13 tables, two bucket-elevators, one trommel, and two Huntington mills.

The Esperanza classifier was invented in the mill of that name, at El Oro, Mexico; it consists of a series of steel-armored wooden flights on a sprocket-chain moving up an incline of 30°, the effect being to drag the sand along the incline while allowing the slime to run back.

The practice in the Bunker Hill mills is to paint the launders so as to trace the various products. Yellow indicates middling, brown stands for concentrate, and gray for tailing.

The main tailing-launders are lined along the sides with concrete slabs, 2 in. thick, 24 in. long, and 12 in. wide, made of tilling and cement. These slabs form a lining that is more satisfactory than cast-iron; they cost 20¢ apiece, as against \$3.50 for cast-iron. The bottom of the launder has cross-rifles, placed at intervals of 24 inches. These are made of white iron, $\frac{3}{4}$ in. thick, 6 in. high, and 24 in. long (the width of the flume). The tailing settles between the rifles and forms an indestructible bed.

SPECIMENS OF ASBESTOS

Asbestos. A Canadian Specialty

By F. C. C. LYNCH

In Roman times the lamp-wick that was not consumed, and the cloth that would not burn were rare curiosities. Today thousands of tons of a mineral fibre superior to the Roman product is used for these and many other essential purposes in industrial and domestic life. A fibre, incombustible and indifferent to fire, time, and weather, a poor conductor of heat and electricity, enduring, and yet capable of being spun into threads of considerable strength and woven into cloth must be of great economic importance, of course. This fibre is asbestos, a Canadian specialty.

It has been found in almost every quarter of the globe, but nowhere of better quality than in the Eastern Townships of Quebec, Canada. In all but one or two cases the quality of that found elsewhere is distinctly inferior and it seldom occurs in paying quantities. Where asbestos of good quality has been found, as in Russia and South Africa, an unfavorable location as regards transportation has made it impossible for it to compete on favorable terms with the Canadian product. Before the War Canada produced 87% of the world's supply of this mineral. With Russia for the present out of the field, Canada's predominant position is obvious. And yet the productive area is small. Although the occurrence of asbestos has been reported and some has been mined in other parts of Canada, nearly all of it comes from this limited area in Quebec. The principal centre of the industry is Thetford in the county of Megantic.

The name asbestos, as commercially applied, covers two distinct minerals, which have, in common, a fibrous structure with both fire and acid-proof qualities. These min-

erals are hornblende-asbestos and serpentine-asbestos, or chrysotile. The heat-resisting qualities of both are approximately the same, but the hornblende variety does not generally possess the same silky quality as the chrysotile; consequently, when strength of fibre, as well as non-conductivity of heat are required, chrysotile only can be used. All the Canadian asbestos is of the latter kind. The essentials that render asbestos of economic value are length, fineness, and elasticity of fibre, tensile strength, and power of resistance to fire. The Canadian chrysotile possesses all these qualities, the length of fibre being one of the principal factors governing its grading.

It has a pearly lustre and although it varies in color from deep green to yellow, yet when drawn out in threads it is white with a silky lustre. It also exhibits extreme delicacy and silkiness to the touch, with great adaptability for spinning, although for a time the fibre produced from asbestos resisted all attempts in this direction. The difficulty arose from its peculiar formation, which, possessing smooth surfaces (unlike wool and silk, whose fibres bear teeth-like projections or imbrications), and being much less flexible than those of organic origin, slipped past each other when subjected to the spinning process. But all these difficulties have been overcome. A single thread of appreciable tensile strength can now be made, weighing not more than an ounce per hundred yards. Temperatures of 2000° to 3000°F. are easily withstood, while on some varieties a temperature of 5000°F. has produced no visible effect.

As to the fibres themselves, microscopical investigations show that each apparently single thread is com-

posed of exceedingly fine filaments, the most minute numbering up to 25,000 per linear inch. The main differences discernible between hornblende-asbestos fibre and that of chrysotile, such as the Canadian product, are the more finely divided nature of the latter and the more glassy tool-like appearance of the former.

"The study of the geological conditions of the district has now fairly well established the fact that the serpentine of the Eastern Townships (the mother-rock of chrysotile-asbestos) is a secondary rock. It is the alteration product of olivine, a rock of igneous origin. It can be conclusively shown that in nearly all cases this anhydrous olivine was changed gradually into serpentine, or a hydrous silicate of magnesia, and that subsequently, through the action of certain agencies, fissures were formed and filled with an asbestos-bearing solution, which gave rise to the ultimate crystallization of the fibre." It would appear that these asbestos-filled fissures were caused by the shrinkage of the serpentine and also by the injection of the granite dikes that are found throughout this area. This would account for the reticulation of these veins and the way in which they vary in size, and also for the fact that they are found to be numerous near these dikes. It is obvious that all these changes took place very slowly and not only on the surface but at depth.

There are two areas in the Eastern Townships producing asbestos—the Thetford, Black Lake, and the Danville, the first district being by far the more important. Large portions of these areas do not, however, contain asbestos in paying quantities. The veins occur in the serpentine, as indicated above, without any special arrangement, intersecting each other and the rock generally in every direction. Their thickness varies from a few threads to several inches. The bulk of the fibre recovered is, however, between a quarter and a half inch in length.

The transportation facilities are excellent; no mining camp in North America can compare in that respect with the Canadian asbestos quarries. It so happens that the productive belt follows closely the winding course of the railway built before the asbestos mines were discovered. No quarries are more than a mile and a half from the track. Moreover Thetford is only 75 miles from Quebec, whence the asbestos may be shipped to Europe, and 350 miles from Boston.

The area in which serpentine is found in paying quantities in this district is computed at not less than 15,000 acres. Numerous bore-holes have been made and it has invariably been found at the greatest depths reached. Many hundreds of feet below the present working levels the character of the rock remains unchanged. Owing to the way in which the veins branch and vary in width and number it is impossible to get a good idea of the extent of the deposits by boring or by sinking shafts. However, since asbestos has been found at 700 ft. and since the deposits of asbestos do not vary in extent or

quality as the quarries increase in depth, it may be estimated that there are millions of tons of fibre and that the industry will have a long life.

Although asbestos was known to the Romans and although Marco Polo, in his travels through Siberia in the 13th century, was shown it there, little use was made of this mineral until about sixty years ago. About this time attempts were made to exploit the deposits in the Italian Alps, and almost simultaneously asbestos was discovered in the Province of Quebec. In 1862 a specimen of fine silky-fibred asbestos from this Province was exhibited in London. But it was not until 1878 that mining operations were begun following the discovery of asbestos in 1877 near Thetford.

The industry rapidly expanded and in 1885 seven quarries were in operation with a production of about 1400 tons of fibre per year. From this date an increase of price resulted in exploitation on a larger scale and dividends up to 22½% were declared by some companies. But this state of affairs did not last long. Prices began to drop, the demand slackened, and in the middle of the 'nineties many quarries were forced to close down, and the industry received a severe set-back.

For some years production languished, but the result was really beneficial. Previously the ore had been treated by hand, with the result that all the smaller fibre was discarded. Then mechanical treatment of the ore was devised, and the industry rapidly re-gained its feet. Uses have been found for all the fibre, even to asbestic sand, and the demand is now so great that the asbestos industry is one of the most flourishing and prosperous in Canada. The production in 1918 was 142,375 tons, the greatest output ever recorded. The value was over nine million dollars. In 1919 the industry was equally prosperous, having suffered no post-war depression.

Owing to the fact that the Canadian deposits occur on the surface the ore was first obtained by quarrying. This is still the general method, chiefly because of the uncertain way in which the veins reticulate and vary in thickness and number. However, this entails certain disadvantages: the removal of waste from barren zones; the exposure of the workmen to inclement weather, which sometimes interrupts operation; and extra expense for drying the ore, which often becomes wet through exposure to snow and rain. All these are serious items. The disadvantages of underground mining are difficulties in supervision and ventilation, costly timbering, and loss of asbestos in pillars. At present the tendency seems to be toward providing underground work for inclement weather, but to retain open quarrying for the remainder of the year.

The rock is drilled, chiefly by compressed air or by electric drills, blasted by dynamite, and then treated according to the grade of the material. The very highest quality of asbestos, the long fibre known as 'crude', is 'hand cobbled', that is to say, the adhering rock is separated from the fibre by hand hammer. This quality represents about 4% of the whole production of asbestos. The rest of the rock is conveyed to the nearby mills where

"Chrysotile-Asbestos", second edition 1910, by Fritz Criket, Mines Branch, Ottawa.

BELL'S PIT, THETFORD MINE.

ANOTHER VIEW OF SAME.

it is crushed, dried, re-crushed, screened, and pulverized in 'cyclones' where rapidly whirling helical screws throw the pieces violently against each other and thus loosen the fibre, which is afterward removed by suction fans and re-graded.

Manufactures of asbestos in Canada are almost wholly confined to the use of the shorter fibres and asbestos sand. The latter is used for fireproof plaster and fireproof paint, while the former is used chiefly in the manufacture of asbestos slate and shingles. These are made of asbestos fibre embedded cross-wise in cement-paste and subjected to heavy pressure. In this way thin sheets are formed having extremely high physical strength, indifference to blow and shock, and great elasticity, properties which are of as great importance in the conveyance and laying of shingles, as is durability. After three months' exposure the asbestos-cement slate becomes impervious to water, indestructible, and as hard as iron. This product may be colored as desired. It may also be used in large sheets in building construction. The future of this industry is very promising and would appear to depend very largely on the price of cement.

Other articles manufactured from asbestos are made chiefly in the United States and in Europe. Among these are cloth, spun and woven from pure asbestos fibre, and used for safety drop curtains in theatres, for theatrical scenery, and for clothing for firemen, and asbestos sewing-twine and rope. A one-inch rope weighing 10 lb. per 100 ft. will carry safely a load of 500 lb. Asbestos-paper and mill board are being extensively used in building construction. They are fire-proof and are poor conductors of heat and sound waves. The fibre is also used for steam-packing for valves and cylinders, being the only permanent elastic and generally satisfactory material available for the purpose, especially for use with super heated steam at high pressure. Still other articles are asbestos-wood which, though fireproof, is capable of being turned and grained and taking a high polish, asbestos-tile for flooring, asbestos-covered metal, filters,

asbestos-leather, non-burn brake-linings, and kitchen utensils. In fact the uses to which this mineral may profitably be put are almost innumerable.

The production of Canadian asbestos has increased very greatly during the past four years and the average price in 1918 was from three to four times that of 1914, so it is evident that the demand still exceeds the supply. Before the War the United States took about one-half of Canada's production, but demand from Europe was growing more rapidly. Now, however, the United States is taking nearly three-quarters of the supply. With the recovery of Europe it may be confidently expected that the European demand will revive, especially for the shorter fibres used in building construction. As these fibres constitute the bulk of the production and have formerly been produced in excess, it is apparent that the Canadian asbestos industry has a prosperous future.

Canada herself is importing from the United States an increasing amount of manufactured Canadian asbestos. It is obvious, and but natural, that she should wish to manufacture these goods at home, and in the not distant future there may be built up in Canada large asbestos-manufacturing industries able to supply the world with the finished product.

CONSIDERABLE ATTENTION has lately been attracted to Trinidad in connection with the boom in oil throughout the world. The shares of companies listed in London and interested in oil developments in Trinidad have lately had spectacular advances, and there seems now a rapid movement to organize new companies to drill for petroleum on the island. The leading companies already seem determined on a policy of further expansion, and in their keen competition for the purchase of lands thought to be oil-bearing, the prices have lately been as high as \$500 per acre, where indications seemed especially favorable; this applies only to private lands, as all Crown or Government lands in the mineral-oil districts have been covered long since by concessions to British companies.

Car-Loading Grating

By WILLIAM S. EVANS

An efficient car-loading grating is in use at the smelter of the Tennessee Copper Co. at Copperhill, Tennessee. It is placed in the crane-aisle of the smelter building at one end on the converter-floor.

This device is used for dumping skulls from ladles by use of the traveling crane. A ladle is tilted over the grating and is swung by running the top earriage of the crane back and forth and striking the movable bumper with the ladle until the skull is loosened and drops out. This is done on one side of the grating, as the ladles can only be

swung and dumped from one side owing to the settler-floor being in such close proximity to the other side. The fall from the ladle to the grating breaks the skull into pieces of various sizes. A spill-plate runs along the opposite side from which the ladles are dumped to keep the broken pieces from spilling over the side. Those that do not pass through to the car below are broken by hand with a sledge-hammer. Also the cleanings from the floor of the crane-aisle, usually the result of runaways from the settlers, are loaded on a scoop or in a ladle which may then be dumped onto the grating by the crane.

The drawings serve to show the general dimensions and the structural shapes used in the design and construction of the grating.

A standard-gauge track accommodates a steel hopper-bottom gondola ear, a special type that is also used at this plant for hauling ore from the mines.

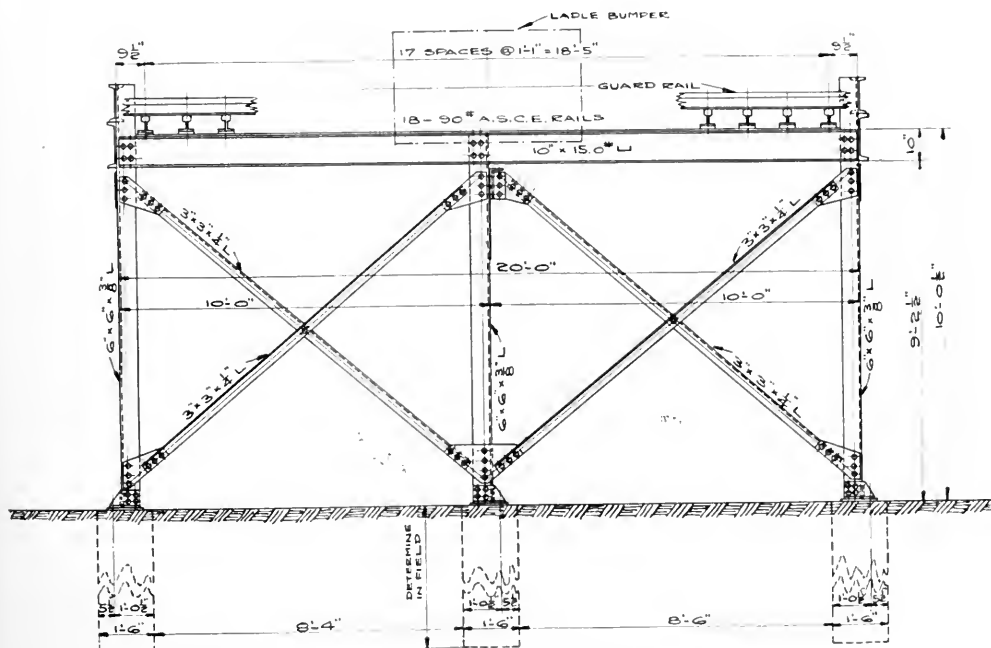

On top of the grating a east-iron cylindrical bumper is used. It is composed of two sections and heavily constructed as shown by the sketch. These two sections are bolted together, and on each end a circular plate with a manhole is bolted. It was the idea, if the bumper was found to be too light, to fill or partly fill it with concrete or sand. This was never done, as the bumper alone was found to be heavy enough.

A cold-water spray-pipe runs the full length of the grating along each side just above the top of the car. This spray against a one-quarter inch plate and the water flows down these plates and down the sides of the car, thereby cooling the side plates of the car and protecting them from possible buckling from hot material. The water drains through to the ground and is carried off by a drain.

SIDE ELEVATION
SIDE BRACES NOT SHOWN

Concrete Mine-Bulkhead

*A reinforced concrete dam was constructed in the 3:19 raise at No. 1 shaft of the Modderfontein East mine, for the purpose of controlling and closing off a flow of water which yielded approximately one million gallons per day at a pressure of 500 lb. per square inch. This stream was cut in the dike through which the raise was being driven, and was found to be coming from a vertical fissure striking north and south. This fissure was found to be filled to a large extent with soft clay, which was not sufficiently solid to resist removal by the water under pressure, with the consequence that as soon as the water was tapped in small quantity a portion of the clay filling was quickly washed out, and, furthermore, the dike material adjacent to the fissure, being of a broken and loose nature, was displaced by the flow until a cavity about 18 in. wide, 6 to 10 ft. long, and 10 to 15 ft. high was created at one corner of the face.

Fortunately the dam was constructed and finished before this continuous stripping action was able to extend across the whole width of the face, thereby preventing a further increased flow of water. A good concrete, consisting of 1 part cement, 1 part sand, and 2 parts broken stone, was rammed into the face to a thickness of approximately four feet. No hitches for support were cut in the rock, but a series of 40 one-inch steel pegs were driven to a depth of 6 to 9 in. into the rock in two rows around the perimeter of the drive; these pegs projecting a distance of about $1\frac{1}{2}$ ft. into the mass of concrete. In addition to this, two rows of $\frac{1}{2}$ -in. bar-iron, one vertical and one horizontal, the bars being about one foot apart, were embedded in the concrete during construction and tied by means of wire to the above-mentioned pegs, thereby forming a double grille system of reinforcement. In this way a thoroughly strong wall was obtained.

The feeder of water was confined behind the concrete to as small a channel as possible with the aid of 21-gauge steel sheets, and released through two 6-in. pipes fitted with stop-valves. By this means it was possible to place the concrete in position correctly without any interference from the water. Six $1\frac{1}{2}$ -in. cementation pipes were also built in the dam for the purpose of filling and solidifying the fissure and the subsequent testing of the ground in advance. While this work was in progress three release holes were drilled into the hanging wall from the front of the dam at an angle of 45° , thereby intersecting the fissure approximately 12 ft. above the back of the raise. Injection was then started on August 19, and continued until August 27, when all the pipes in the dam had been solidly closed with cement, and also two of the release holes in the hanging wall. At this stage approximately half the original feeder was shut off, but, owing to shortage of cement, it was not deemed advisable to close it all off. Sufficient cement was obtained on September 1, and injection continued for two days, when all the release holes in the hanging wall were completely

finished, thus effectively shutting off all water. Four tons 14 cwt. of cement was used in the concrete construction; 25 tons of cement was injected at pressures ranging from 25 to 220 lb. per square inch, giving a total quantity of 30 tons of cement used for closing off this fissure. After completing the dam and shutting off the water, the mode of procedure consists of testing the ground in advance by means of bore-holes, and, if additional water-bearing fissures are cut, cementation is conducted, so that the drive may subsequently be extended through the water zone without encountering water, the ferro-concrete dam being in the first place removed by blasting.

Platinum in British Columbia

The following notes on platinum are from J. B. Hobson, the manager of the Consolidated Cariboo hydraulic mine, situated in the Quesnel district in British Columbia: For several years, qualitative tests have been made from time to time for the presence of gold, platinum, and osmiridium in the heavy concentrates that remain in the sluices after cleaning up; and while making one of these tests in May 1903, the presence of palladium was indicated in addition to platinum and osmiridium. An analysis of a sample of concentrates, made by J. O'Sullivan, chemist, of Vancouver, in May 1903, gave large quantities of gold, platinum, palladium, and osmiridium, which brought the value of the concentrate up to \$3873 per ton. A second sample taken from a pan of concentrate taken from the sluices after the clean-up in September 1904, was sent to Mr. O'Sullivan and gave the following results:

	Ounces per ton	Value per ton
Gold	95	\$1900.00
Silver	180	90.00
Platinum	64	832.00
Palladium	64.4	1769.00
Osmiridium	42	1386.00
Copper, per cent.	10.5	16.56
Total value		\$5993.56

The gold and silver are, no doubt, included in particles of pyrite and argentiferous galena, and partly in small particles of gold covered by manganese and other metallic oxides, and cannot be recovered by the process of amalgamation. The platinum, palladium, and osmiridium are found in minute metallic grains and enclosed in small fragments and nuggets of magnetite and chromite, which appear to make up quite a large part of the sluice-concentrate found after cleaning up. What quantity of this high-grade concentrate is included in the deposits, or can be recovered therefrom, cannot be determined until after the completion of the system of undercurrents which is to be placed at the end of the sluice outside the tunnel, where everything of value will be separated from the tailing, before going over into the dump, and concentrated on the undercurrent tables. These undercurrents will probably be completed before the close of the ensuing season.

*Abstract of a paper by Thomas Blandford in the *Journal of the S. A. I. E.*

Operations of the Nevada Wonder Mining Company During Four Years of War

By E. E. CARPENTER

The World War caused various fluctuations in the operating costs and profits of silver mines in the Western States, as a result of the increased cost of labor and materials and the coincidental rise in the price of silver. The effect on net profits is shown in the information available in the reports of operations during recent years of the Nevada Wonder Mining Co., from which sundry interesting comparisons may be made.

The production of silver from this mine decreased gradually from 1915 to 1919 in consequence of the depletion of the ore-reserves and the necessity for treating ore of lower silver content. The higher price of silver offset the increased costs and permitted this lower-grade ore to be worked at a profit. Had it been possible for the mine to continue producing ore averaging 20.84 oz. silver and 0.176 oz. gold—the tenor of 58,124 tons treated in 1915—the enhanced price for silver would have enabled the payment of greatly increased dividends. Like the great majority of silver orebodies, however, this one had been bottomed at a comparatively shallow depth. The stopes in the immediate vicinity of the Nevada Wonder shaft produced only a small tonnage below the 600-ft. level, although the Extension orebody was continuous for 1000 ft., from the 300 to the 1300-ft. level of the Nevada Wonder shaft; the former corresponding to a depth of 100 ft. from the outcrop of the lode, thus giving the orebody a vertical depth of 1100 ft. from the surface. However, it is fair to mention that over two-thirds of the bullion was derived from ore that was mined within approximately 500 ft. of the outcrop.

During the year 1918 the company treated 49,710 tons of ore for a total net operating profit of \$179,548, equivalent to \$3.61 per ton. The average content was 0.103 oz. gold and 13.23 oz. silver per ton, showing a decrease of 0.038 oz. in gold and 3.42 oz. in silver as compared with the preceding year. The average price for all the silver sold was \$0.966 per ounce. Table No. 1 affords a comparison of the metal content and value of the ore produced from 1915 to 1918 inclusive. The gold content decreased gradually, showing a total decline of 41.5%, while the silver content decreased 36.5%. The value of silver increased from a nominal quotation of 50 to 96.6 cents per ounce, or 93.2%. The ore treated in 1918 would have had a value of only \$8.75 if mined during 1915, as compared with the actual realized value of \$14.93.

Table No. 1.—Content and Value of Ore

Year	Gold, oz.	Silver, oz.	Value per ton	Average price of silver
1915	0.176	20.84	\$13.97	\$0.500
1916	0.159	18.72	15.40	0.047
1917	0.141	16.65	16.45	0.817
1918	0.103	13.23	14.93	0.966

Having compared the contents and value of the ore during this period of four years, it will now be useful to compare all the costs in connection with the mining and milling operations. Table No. 2 compares the direct, indirect, and total mining costs. The tonnage treated each year did not vary sufficiently to account for any considerable variation in costs, which must therefore be attributed to changing labor and market conditions. The lower direct cost for 1918 as compared with 1917 was caused by a decrease in development work, which was discontinued largely both downward and laterally, after the vein had been explored for 4500 ft. along its course and to a depth of 2000 ft. Had it not been for this change in policy about the middle of the year, the cost for 1918 would have been greater than for any preceding year. The average amount of development work during this four-year period was approximately 750 ft. per month.

Table No. 2.—Mining Costs

	1915	1916	1917	1918
Direct cost	\$3.33	\$4.46	\$5.41	\$1.48
Indirect cost	0.83	0.83	0.97	1.01
Total cost	\$4.16	\$5.29	\$6.38	\$2.49
Average cost per foot of development work	\$7.70	\$9.31	\$11.05	\$11.65

Note: Transportation to mill was not included.

The direct per-ton cost of mining was divided as follows:

Table No. 3.—Mining Cost, Segregated

Year	Labor	Supplies	Explosives	Power	Total
1916	\$2.965	\$0.713	\$0.369	\$0.212	\$1.16
1917	3.587	0.690	0.580	0.254	5.11
1918	2.997	0.699	0.231	0.271	4.18

The corresponding direct cost for milling is shown in the following table divided under the three headings: labor, supplies, and power.

Table No. 4.—Milling Cost, Segregated

	Labor	Supplies	Power	Total
1915	\$0.705	\$1.166	\$0.394	\$2.265
1916	0.753	1.611	0.367	2.731
1917	1.052	2.031	0.435	3.518
1918	1.108	2.002	0.482	3.592

Table No. 5.—Combined Mining and Milling Costs and Profits

	1915	1916	1917	1918
Total mining cost per ton, including transportation	\$4.19	\$5.23	\$6.43	\$2.58
Total milling cost per ton	2.81	3.31	4.12	4.26
Marketing cost per ton	0.27	0.26	0.23	0.25
Total cost per ton	\$7.27	\$8.80	\$10.78	\$7.09
Average value per ton	\$13.97	\$15.40	\$16.55	\$14.93
Loss in tailing per ton	0.82	1.13	1.50	1.22
Recovery per ton	\$13.15	\$14.27	\$15.05	\$13.71
Less total cost per ton	7.27	8.80	10.78	10.09
Profit per ton mined and milled	\$5.88	\$5.37	\$3.97	\$3.62

Note: The high loss in tailing in 1917 was caused by treating sulphide ore before concentrators had been secured.

Table No. 5 shows the total mining and milling costs, direct and indirect, cost of transportation to mill, mar-

ketings, taxes, and depreciation; in fact, all charges properly made on mining account. The average value of the ore, loss in tailing, recovery, and the all-important item of profit-per-ton of ore treated, are also shown.

An effort to show the increased cost of producing an ounce of silver led to the compilation of Table No. 6. The ratio of gold to silver remained fairly constant, so the value of all gold produced each year was deducted from the total cost for the corresponding year; the then remaining cost of operation represented the cost of producing the silver. Dividing this cost by the number of ounces produced gives the figures, under the caption 'cost per ounce of silver after deducting the value of gold', which show a gradual increase from 18.2 to 64.6 cents.

Table No. 6—Summary of Cost of Producing Silver

Year	Gold, oz.	Silver, oz.	Value of gold	Value of silver	Total cost	Cost per ounce of silver after deduct-		Recovery per ton	Average price of silver	Tons milled	
						less value of gold	ing value of gold				
1915	9,800	1,123,398	202,612	561,700	407,182	204,570	0.182	0.169	19.30	0.500	58,124
*1916	10,933	1,243,753	220,006	805,237	624,576	398,570	0.320	0.151	17.20	0.648	72,241
1917	7,513	816,853	155,255	667,085	588,913	433,658	0.539	0.135	14.64	0.817	55,800
1918	4,877	601,665	100,444	581,165	489,044	388,600	0.646	0.098	12.10	0.986	40,710

*15 months.

These figures, of course, apply to one particular mine, which unfortunately faced a gradual decrease in the grade of ore treated during the four years considered. It is a fact, however, that a number of other silver mines in Nevada were working under similar conditions.

Magnesia Cement to Protect Mine-Timbers

By W. C. PHALEN

*For mines that are situated in out of the way places, where timber is scarce and its price high, the problem of protecting it from fire is important. Scarcity of timber for mining purposes commonly exists in the more arid parts of the country, where, also, mine-timber is most likely to become dry and inflammable, and where, therefore, the risk from fire is accentuated. Any effective and cheap method of securing adequate protection of such timber at the lowest possible cost is worthy of careful investigation. The use of magnesite cement has been suggested in this connection.

The necessary qualities for any substance for this use may be summarized as follows: It should be resistant to abrasion, to impact, and to structural stresses. It should be durable when subjected to the action of the elements, and stable to any minor derangements of the base on which it is placed. It must be relatively unaffected by changes in temperature, or by the action of water, and should adhere to the material on which it is placed; and it should also be free from shrinkage cracks due to setting of the material.

Magnesite cement appears to fulfil these conditions. Its elasticity is the outstanding quality that makes it par-

ticularly desirable. The quality of adhesion and elasticity is easily proved by applying a $\frac{1}{2}$ -in. layer to a 1-in. board which first has been covered with metal-lath. Such a board, about 8 ft. long, may be repeatedly deflected 3 in. in the centre without breaking the bond to the board or causing any cracks to appear in the magnesia cement. The ability to resist fire as well as the possession of insulating qualities are also desirable characteristics of magnesia cement.

Magnesite cement should be applied in two coats, each $\frac{1}{4}$ in. thick, on various surfaces such as wood-lath, metal-lath, sheathing-board, brick, hollow tile, or stone. Care should be taken if lime is present, unless this has been rendered, or has become inert, as with very old walls. The first coat is made to a consistence that works easily

under the trowel, and is applied in the usual manner. No water should be added to the liquid chloride as it would alter its density, and injure the work. The second or finishing coat is then applied. The aggregates are different in each, and no other dry material should be added to them as they come to the trade. The cement may be applied in zero weather without damage. Setting is quite slow under such conditions, but it ultimately becomes hard. It should always be applied to a dry surface except that under certain conditions it is desirable to apply a solution of magnesium chloride first.

The temperature is of importance. If the temperature is over 50°F., only so much of the first coat should be applied in one day as can be covered with the second coat. In this way, the finishing coat is applied before the first coat has become hard. If the temperature is below 50°F., the finishing coat can be applied 24 hours after the first coat is applied.

Abundant supplies of magnesite occur in California and Washington, in close proximity to regions of large mining operations. The cost of transportation of such material would, therefore, be correspondingly reduced. Magnesium chloride is also an essential ingredient in making magnesia cement. Supplies of by-product magnesium chloride, produced in connection with the solar evaporation of salt along the Pacific Coast, have been largely wasted heretofore. Any development of a magnesia cement industry on the Pacific Coast ought to stimulate greatly the conservation of this chloride as well as the demand for Western magnesite, if the suggested use for magnesia cement is found practicable. Such use should also tend to place Western magnesite on a more secure basis by enlarging what is peculiarly a domestic application, and in which, moreover, there would be little danger of serious foreign competition.

*From Reports of Investigations, Bureau of Mines.

Hanging-Wall Support on the Far East Rand

By L. W. MACER

*The problem of the support of the hanging wall in the deeper mines of the Far East Rand has engaged the attention of the mining men concerned for some time past. The objects of these notes are, firstly, to place the problem before those engineers who, not being conversant with East Rand mining, may have been faced on other fields with similar conditions, and, secondly, to bring forward suggestions for the utilization of waste material, such as old ropes and pipes, in the construction of roof supports.

An opinion has been widely held that the panacea for hanging-wall trouble in flat mines lay in the adoption of colliery practice, but to the writer, and to others who have come to the East Rand with coal-mining experience, it has become apparent that to deal with a colliery roof is an entirely different proposition from the support of an East Rand hanging wall. The difference is best explained diagrammatically. In Fig. 1, *A* represents a section of a longwall face, and *B* a flat stope face where hanging-wall trouble has become acute. The forces acting and the direction of those forces are precisely similar in both cases, yet the effects are very different. The hanging in *A* has subsided in a gradual manner, its surface approximating a curve from the coal face to the filling, whereas in *B* cracks have developed at and parallel to the face, and the hanging throughout the stope has broken up and has none of its original stability. The result is the development of a danger zone between the last support and the face, which means that work has to be carried on in a veritable death trap, while in coal mining perhaps the safest place in the mine is at a systematically propped longwall face.

The reasons for the difference in the conditions of the hanging wall are:

- (a) The difference in the relative rates at which the faces of the coal and the vein are worked.
- (b) The initial resistance of the supports used in the different classes of mining.

The difference in the rate of advance of a stope face and a longwall face is, of course, considerable. A stope face equipped with machines breaking one fathom per machine shift will only advance about 12 ft. per month, the general average for a mine being much less than this, while a longwall coal face equipped with disc coal-cutters and mechanical conveyors will advance the depth of their cut, namely, 4 ft. 6 in. to 5 ft. per 24 hours. To the relatively slow advance of a stope face, I attribute the difference in stability of roofs, although the heavy blasting and sometimes indiscreet placing of holes in stoping, no doubt, is contributory to the effect.

Coming to the second reason, it is observed that the props used in longwall systematic timbering have a considerable initial resistance, while cribs used in stoping have practically no initial resistance; in fact their maximum resistance is not reached until they become compressed by about 20% of their original height. This amount of compression is observed at varying, but generally at considerable, distances from the face. The hang-

Fig. 1

ing wall is therefore supported at two points, namely, at the point in the stope where the cribs have reached their maximum resistance, and at the face. It therefore follows that fracture may be expected at and parallel to the face or in proximity to any pillar left in the stope. Practically, we have the phenomenon of 'punching'.

The comments to be expected upon the above statements will no doubt be that there is no originality in

Fig. 2

Fig. 3

Fig. 4

them; secondly, that stope faces cannot be advanced more rapidly; thirdly, that props, notwithstanding their initial strength, are impracticable in deep-level flat mines; and, finally, that as a cure seems impossible the trouble must be endured. The difficulties above outlined have been recognized, and steps have been taken to combat them; the remaining remarks refer to such improvements as have been already adopted and suggestions for further improvements.

IMPROVED SUPPORTS AND METHODS. An increase in initial resistance of cribbing has been to a certain extent effected by driving wedges into the split ends of the lagging of which the crib is built. This method is not so effective as might be supposed, and an improved method of wedging without splitting the sticks has been introduced. A split stick (half-round) is placed flat side

*Reprinted from the Journal of the Chemical, Metallurgical & Mining Society of South Africa.

down in about the centre of the crib. A long wedge of small taper is driven in below the split lagging and rests in a square joggle in the next underlying stick. By driving home these long wedges the whole of the upper portion of the crib is forced up to the hanging.

Well built dry masonry has been used in preference to cribbing. A pack 20 ft. square with rounded corners is used. These packs, in addition to giving a good initial resistance, resist blasting better than cribbing. They are built by experienced masons, and the cost appears to be rather higher than for building cribs. The masons at 20s.* per day handle about three tons of stone, which does not, however, compare favorably with a surface mason's day's work of two and a half cubic yards.

The use of pillars in conjunction with the above mentioned supports is the generally recognized practice, notwithstanding that even the greatest advocate of the pillar admits its disadvantages. In deep-level mining it is difficult to demonstrate the utility of the pillar except under special circumstances, such as the support of faulted ground or in the process of the reduction of stoping widths.

A method, comparatively recently introduced, known as the 'Panel System', makes use of pillars regularly placed and subsequently removed. It approximates the pillar and stall method in colliery work, the stalls being from 70 ft. to 120 ft. wide with pillars of 30 ft. It is undoubtedly the best method of controlling roof weight in a stope where the face advances slowly, and it effectually obviates the dangerous condition mentioned in the earlier portion of this paper.

The crib has the great advantage over masonry in cost of construction, as comparatively unskilled labor can be used. It has the disadvantage of being easily damaged by blasting unless it is carefully built and unless the stope timberman and machine man work amicably, a condition which it is difficult to obtain in practice.

Fig. 3 illustrates a design that should allow of good construction by an indifferent workman and should result in a crib that it would be difficult to blast out. Four posts are set in such a manner that the ends of the horizontal sticks do not project beyond them. Old wire rope is then passed round the posts as shown in the figure. These ropes are drawn as taut as possible, and finally tightened by means of twisting by the insertion of a piece of pipe or jumper at the point A. The frame is then filled with stone.

Fig. 4 shows a similar construction, but using wire rope in place of the horizontal sticks.

Fig. 2 uses old pipe filled with concrete for the posts. A plug of wood is used in the upper ends of these posts and answers two purposes; it allows a certain amount of compression, and can be easily sawn to adapt the length of the post to the angle of the stope. Wire rope is again used as in Fig. 4.

In conclusion, it may be mentioned that the question of the support of roof in the East Rand mines would be much more acute if it were not for the fact that owing to

unpayability, almost half the area remains unmined. As more mines become worked, however, the roof must become more troublesome and the lay-out of underground workings and methods of mining that have been more or less satisfactory in the past will in all probability be found wanting in the future.

In the discussion following the reading of this paper the following comments were made:

By J. Chilton: "The subject of hanging-wall support is interesting to all men who go down to the mines, and although the East Rand district has not really reached its troubles yet, still the time will come, and a new method of support may have to be invented for the flat mines of that district.

"Mr. Macer speaks of leaving temporary pillars. Some of us in the central area have had a good deal of experience with pillars, and the general opinion is that rigid supports are not only a danger to the persons working round about, but are also a danger to surface property. Almost every earth-tremor, and these are numerous, is caused by the bursting of pillars, and where this does occur the punching effect causes falls of hanging that otherwise would not occur. To my mind, the leaving of pillars is a mistake, apart from the expense of cutting them, and cribbing forms the ideal support for hanging walls.

"It is encouraging to know that the mining people of the East Rand are taking up the idea of roof support and that they are evolving new forms. The cribs mentioned by Mr. Macer, and which are I believe his own invention, are novel in construction and are probably effective; but of new forms of this support there is no end, each probably limited in its application to the particular mine where designed."

By J. Gibson: "To those of us who are engaged in mining operations, this is a most important subject, and one which has lent itself to numerous discussions, which have probably brought about a good deal of improved practice in supporting the workings in the mines. The question of leaving pillars for support has been a vexed one, and in the Central Rand area has been the cause of many serious bursts. Generally speaking, the practice is to support the hanging wall by less rigid methods than the leaving of solid pillars. This method has been advocated time and again by different members, and where it has been practised I think it has led to a reduction in serious accidents and probably better mining."

THE USE OF SLATE for roofing is apparently on the decline, although a part of the falling off in production in recent years is due to war-time curtailment of building, according to a report recently issued by the U. S. Geological Survey. The major part of the slate produced in this country is, contrary to the general impression, used on the inside rather than the outside of buildings, for such purposes as making stationary washtubs, electrical switchboards, and blackboards, and the output for these purposes has been practically uniform for the last twelve years.

*\$3.75 at present rate of exchange.—Editor.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

VERDE M. & M. CO. STARTS ITS MILL.

HUMBOLDT.—The Blue and DeSota mines of the Consolidated Arizona Smelting Co. shipped 13,400 tons of ore in February. The mill handled 8850 tons of ore and the smelter treated 8150 tons. Part of the ore treated was of foreign origin. 910,000 lb. of copper was shipped to Eastern refiners.

JEROME.—The Verde Mines & Milling Co., whose property is situated seven miles south of Jerome and was formerly owned by the Monarch company, commenced milling on March 18. The ore now being treated is said to run \$25 per ton in gold and is largely free-milling. Part of the ore will be examined in a 30-ton cyanide annex on the property. Since operations were com-

menced by the new company in January, the mill has been remodeled, new buildings erected, a five mile road re-built, 5500 ft. of water line laid, and the underground workings cleaned out and re-timbered. Development has opened new ore.

Operations at the Jerome Superior mine are progressing rapidly. A new steam driven compressor has been installed and another big pump is to be placed on the 700-ft. level. A three-inch pipe-line, 3000 ft. long, for handling fuel-oil has been laid from the V. T. & S. railroad. Two diamond-drills are operating on the 700-ft. level. A flat hole is being run westward and another hole from the east cross-cut has advanced 115 ft. Development on the 700-ft. level has proved the existence of a large body of schist and a well-defined contact. The shaft is now down 750 feet.

KINGMAN.—An attempt by minority stockholders to stop the sale of treasury stock by the Schuylerkill Mining Co. to a New York company has been defeated by the decision of Judge Bollinger of the Superior Court.

PHOENIX.—It is reported that the Eyrich Gold Mines Co., whose mine is 18 miles north of Phoenix in the Winifred district, is building a 15-ton Nissen-stamp mill. The shaft on the property is down 360 ft. and drifting both north and south on the vein has opened ore said to average \$28 per ton in gold.

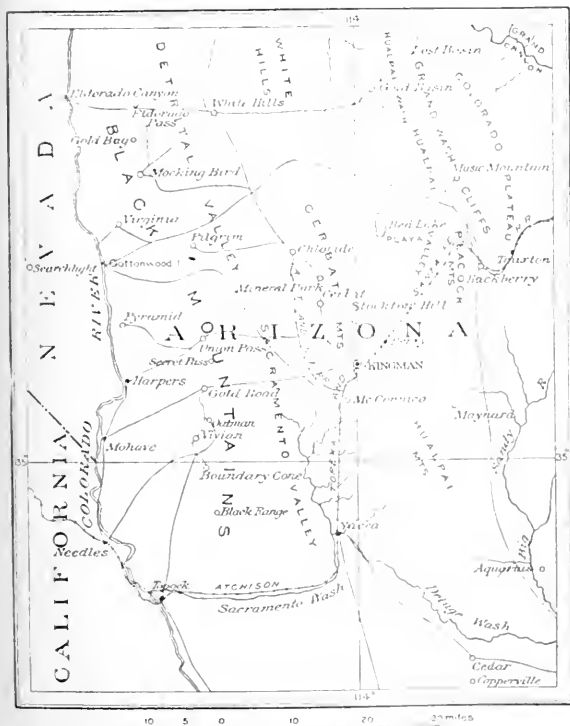

SUPERIOR.—A strike of high-grade ore is reported as having been made on the Chloride group of claims in Russell gulch. The property has been operated for a number of months by William Crawford and associates. A 12-in. vein of ore assaying 34% copper, several hundred ounces silver, and \$150 in gold has been opened. It is said that there are several carloads of ore available.

SWANSEA.—It is reported that the Swansea lease is to make extensive exploration on the 600-ft. level. A double-drum hoist has been installed. The mill is treating about 8000 tons of ore per month.

COLORADO

DIVIDENDS FROM CRIPPLE CREEK.

CRIPPLE CREEK.—John W. Sheaffer, Judge of the District Court, this week denied the application of L. T. Gray, claiming interest in the Moffat tunnel property, for a writ of injunction to pre-

Bulletin 397, U. S. Geological Survey

MAP OF ARIZONA

vent connection with the tunnel from the Blue Flag mine workings. The War Eagle Consolidated Mines Co., the Blue Flag Gold Mining Co., the Moffat Tunnel & Transportation Co., and Hildreth Frost, attorney of this city, were named as defendants. It was alleged in the complaint that damage would result "through the filling of the tunnel with bad air" if connection were permitted. The War Eagle company is cross-cutting from its 1200-ft. level of the Blue Flag shaft on Raven hill to connect with the tunnel, in accordance with a contract with the Blue Flag Gold Mining Co., of which corporation Tully Scott of the Supreme Court of Colorado is president. With connection made, ventilation will be afforded to the Blue Flag and War Eagle mines as well as to the tunnel.

The Golden Cycle Mining & Reduction Co. will on April 10 pay the regular monthly dividend of three cents per share, amounting to \$45,000, and it is expected the regular quarterly dividends of the Portland and Vindicator companies will also be paid on the regular dates. The Portland dividend is at the rate of two cents, totaling \$60,000, and the Vindicator dividend, one cent, totaling \$15,000.

Two train loads of ore making a total of 39 broad-gauge cars, containing about 1400 tons, were hauled from the district on March 29 to the Golden Cycle mill at Colorado Springs. The companies contributing shipments were the Cresson, Portland, Vindicator, and Eagle Sampling, and lessees on the Strong, Jerry Johnson, Trail, Star of Bethlehem, and Index mines.

MICHIGAN

WOLVERINE.—MAYFLOWER.

HOUGHTON.—The Wolverine company is not touching its mine-pillars. From the 40th level upward it now is working out the old stopes and getting fairly good ore. The Wolverine production for the month of March was not large, but it will get back to normal in April if present improvement continues. During February there was considerable difficulty at the Wolverine owing to the flow of mine-water from the South Kearsarge. But this trouble has been remedied. When the South Kearsarge water came in the Wolverine had to keep bailers at work much of the time, thus interfering with the production of 'rock'.

There are a good many people in the Lake Superior district who continue to hold their Wolverine stock and who believe that the company has a possibility of expansion. In addition to the fact that the old stopes are by no means exhausted there always is the hope of the development of ore in some of the other amygdaloids. These will be opened by cross-cuts. Work done some years ago in a limited exploration program showed some possibilities that the management now feels justified in developing. Exploration will be carried on east of the shaft. In addition to the cross-cuts some diamond-drill work will be conducted. There are data enough already at hand to warrant the corporation in expending a reasonable sum on such work.

Mayflower's underground exploration at this writing

is showing encouraging results. The bottom of the shaft carries good looking ore in the foot-wall of the vein. The lateral work, that has been going forward from a point 1709 ft. from the surface, is continuing to supply accurate data of the lode exploration. The north-east drift is 160 ft. from the shaft. The first 50 ft. of this distance was through good ore. Then the drift ran into a badly broken area which continued for 70 ft. This was followed by 40 ft. of trap, but the breast is, at this time, in amygdaloid. It will be continued in a north-easterly direction so long as the results warrant. At a point 140 ft. from the shaft the deposit indicated a turn and a cross-cut was run 60 ft. to the south-east.

The cross-cut to the north-west is now in a total distance of 85 ft. This was in copper-bearing formation to a greater or less extent for the entire distance. The extension today opened up a grade of rock that is highly gratifying and better than anything so far found in this direction. At a point 40 ft. from the shaft a drift was run from this cross-cut and now is in 30 ft. This entire distance was favorable and the breast now is in fair looking material. Altogether the exploration of the vein at this level is meeting expectations in that it is furnishing accurate data relative to the characteristics of the vein. That is the prime importance. The percentage of discard in underground work was 19, a total of 173,679 tons from 898,346 tons of 'rock' hoisted. In No. 2 shaft 50% of the ground is available for stoping. Three-quarters of the distance developed in No. 4 is suitable for mining. In No. 5 shaft the bottom is in trap 37 ft. below the 19th level and about three-quarters of the opened ground can be mined. In No. 6 shaft 45% is ground that may be taken out. Greatest interest centres in No. 7 which is not now working. The seventh level, south, was extended to the point 1741 ft. from the shaft or beyond a point midway between No. 7 and the proposed location of No. 8. Most of the drift was in good quality material but the last 80 ft. was poor.

MONTANA

SILVER ORE FROM NEIHART DISTRICT.

NEIHART.—The Cascade Silver Mines Co., operating the Moulton mine, reports two recent discoveries on its property. The first, on the 700-ft. level, cut a 10-ft. shoot assaying 150 oz. silver that is improving in depth. On the 1300-ft. level a new orebody has been exposed for a width of 10 ft., the ore assaying 60 oz. Neither the hanging nor foot-wall has been reached yet. It is planned to extend a drift for 1000 ft., not only to show the extent of the ore but to give the mine an opening 300 ft. lower than the hoist. This, it is estimated, will save \$5000 per month in haulage of ore and of mine supplies. One hundred men are employed at the mine. The February production amounted to \$65,000.

The Neihart Mining Co. shipped 6 cars of ore to the Washoe smelter during the month of March, averaging 35 oz. silver and 80c. gold per ton. Twenty-eight men are employed.

JEFFERSON COUNTY.—The Mount Thompson Mining &

Milling Co. has been organized to finance the development of the Rhinehart mine, in the Cataract district. The mine is developed by tunnels which will be extended. New shaft work will be undertaken.

HAMILTON.—Philadelphia capital is behind the development of 14 claims located on Treasure hill. During the old boom days these claims were worked to a depth of 250 ft. and considerable silver and lead was developed though none was shipped.

HELENA.—The King Solomon mine in the Lump Gulch district has made its first shipment. The property is being operated by P. A. Danaker and associates. On the 750-ft. level of the Liverpool mine a new orebody has been opened for a distance of 100 ft. with an 18-in. face of ore assaying 35 oz. silver per ton. It is planned to commence stoping this ore soon.

SAN COULEE.—The Anaconda company has signified its intention of developing its coal mines, where 50 to 75 men will be employed until capacity production is reached. Houses are being built for the workmen and other necessary buildings are being constructed. The Great Northern railroad will be asked to build a spur to the mine.

LIBBY.—The Treasure Mountain Mining Co. capitalized for \$200,000 has been organized to develop three promising claims adjacent to the Luckens-Hazel mine about nine miles south of Libby. Preliminary work has uncovered good veins of lead-silver ore.

NEVADA

LESSEES ON FLORENCE ARE ACTIVE.

GOLDFIELD.—Seventeen mine-ears of ore have been broken from a new find of ore in the Cracker Jack lease on the Florence. Fifteen ears assay \$285 and two assay \$500 per ton. The ore is being taken from 30 ft. above the 358-ft. level, north of the Little Florence shaft, where a 2-ft. seam parallel to the main vein has been opened. It is estimated that from 15 to 17 tons of ore is ready for shipment. The seam is in the hanging wall of the vein, east of the Florence Divide stope, which is in the foot-wall. A drift has been driven 60 ft. north in the ore-shoot opened by the Silver Pick in leased territory and a raise has been driven 30 ft. from the intersection of the cross-cut through the vein with the drift. The value of the ore in the raise is from \$15 to \$40 and the drift, partly in the hanging wall of the vein, assays from \$5 to \$11. A cross-cut to explore 150 ft. under where the present work is being done is to be started.

QUARTZ MOUNTAIN.—Quartz mountain, 12 miles east of Goldfield, is the scene of a gold find that has been visited by many Goldfield and Tonopah engineers, who say the district has great possibilities. Only surface prospecting has been done, but the engineers say the width of the vein and assays secured are unusually promising.

WEST DIVIDE.—The West Divide is drifting north from a tunnel cutting the vein at a depth of 150 ft. and indications are that considerably more work will have to be done before the ore-shoot opened in the shaft is reached.

GIBRALTAR.—Recent work in the Gibraltar has proved the average value of the big quartz vein to be much lower than surface assays indicated, according to reliable reports, and it is said that much greater depth than is reached in the present work must be gained before good results can be expected.

THE CANYON. It is expected that in two or three weeks the holders of the option on the Ingalls will start work on a good scale. It has been decided that the mill cannot treat the desired tonnage and a number of other plants are under consideration for purchase. The first mining to be undertaken will be the sinking of the shaft an additional 100 feet.

NEW MEXICO

TWO NEW MILLS.

GRANT COUNTY.—The New Mexico Mining Co.'s concentrator, two miles south of Pinos Altos, is completed and has started on lead-zinc ore from its own and other mines in the district. The mill has a daily capacity of

DIAMOND-DRILLING OPERATIONS IN THE MOGOLLON MINE,
NEW MEXICO

100 tons and is equipped for concentration with tables only. Experiments with flotation will probably result in the addition of flotation-machines. Development in this district had been greatly hindered by the complex nature of the ore found, and the operation of this mill on custom ore should greatly stimulate production. There is no other mill operating in this district.

HIDALGO COUNTY.—The Co-operative Mining Co., of Lordsburg, of which H. C. Walter is superintendent, has completed and lately put into operation a 50-ton mill equipped with ball-mills and straight flotation. The company, organized in 1919, has been steadily developing its ground and has several thousand tons of high-grade silver ore on the dump and a large tonnage blocked for mining. Active in the district also are the Ruby Silver Mining Co., owning adjoining ground, and J. C. Woodward, of Silver City, who is leasing on the Minneapolis mine.

OREGON

THE SILVER KING MINE.

MARION COUNTY.—The Silver King property consists of twelve lode claims, situated on the west slope of the Cascade mountains, and is reached by 20 miles of wagon-road leading up the Little North Santiam river from Lyons. Gold, silver, lead, and zinc are found in a system of three well-defined fissure veins. The widths are, respectively, 18, 20, and 130 ft., the last being known as the Queen of the West vein, on which considerable development work has been done. These drifts show a fair grade of ore throughout their entire length, the average contents being as follows: gold, 0.04 oz.; silver, 10 oz.; lead, 5%; and zinc, 31%. The silver is generally associated with galena. However, silver in the form of argentite has been found. The zinc is found as sphalerite or its alteration products. The Silver King vein, which has a width of 8 ft., has a shaft 80 ft. deep. No development work has been done on the Queen of the Mountain vein, but its surface outcrop shows 20 ft. of profitable milling ore.

The company is now preparing to drive a cross-cut tunnel 1000 ft. long which will cut all three veins at a depth of 650 ft. At the present time a power-plant consisting of a 6-ft. Pelton water-wheel and a 12 by 14-in. Ingersoll-Rand air-compressor is being installed. Henline creek, which crosses the property, is to furnish water-power to operate the plant. The portal of the tunnel is at the foot of Silver King falls. At this point the creek has a sheer fall of 150 ft., and its volume during the driest season is never less than 60 cu. ft. per minute. If the veins cut by this tunnel are of the same character as those found in the upper workings, a flotation-plant will be built to make a concentrate which will be transported by auto-truck to the railroad. The Silver King mine is not a new discovery; it is stated that the early settlers and trappers made bullets from the rich silver-lead ore taken from the veins crossing Henline creek. Until recently, however, the district could not be reached except by pack-horses. With the building of the wagon-road along the North Santiam river development work was started. The company is organized under the laws of Oregon, and its officers are J. J. Langmack, E. E. Williams, and William S. Risley.

UTAH

SHORTAGE OF MINERS IN THE STATE IS ACUTE.

SALT LAKE CITY.—Shortage of miners is becoming so acute in Utah that many mines which operate entirely on company account are almost face to face with the alternative of going over to the leasing system or curtailing operations to one shift per day. The shortage is especially acute in the Park City district, where many more miners could be used; it being said that one company alone could use at least 90 to 100 more men. There are many districts in the State from which very little is being heard, but where mining activity is on the increase. Many good miners have entered districts which have been quiet for years and are said to be leasing old mines which can be

turned into paying ventures under present metal prices. Then, the leasing system adopted in a number of the larger mines of the State has permitted miners to make more than wages, so that a larger number are going into the leasing 'game'. Need for some real action on the part of mining companies to teach unskilled laborers how to mine was never more apparent. There are plenty of intelligent Americans who, it is believed, would welcome the opportunity of earning their living while learning how to become miners, at which employment they could double the wage they receive as laborers. For some time the Silver King Coalition Co. at Park City has been doing more or less work along this line. Young men of more than average intelligence are given employment as muckers and then gradually taught to become miners. However, it is said that the men hardly learn the business before they leave the company and take a lease in one of the other properties.

The mining, milling, and smelting operations of the Anaconda Copper Mining Co. are presented in great detail in an 8000-ft. moving-picture film, which was shown at the Strand theatre in Salt Lake City on March 29. The pictures were lent without charge by the Anaconda company to the Utah Chapter of the American Mining Congress and the State Industrial Commission to assist in the mine-safety campaign in this State. The underground scenes, which include drilling, timbering, tramming, and a picture of an actual blast, were taken by means of special arc lamps. The smelting and refining scenes are especially complete, showing interiors as well as exteriors of furnaces, shops, and laboratories. Causes and means for prevention of accidents are presented at intervals in the reels.

BINGHAM.—During 1919, the Utah Consolidated Mining Co. produced 126,893 tons of copper ore and 45,337 tons of lead ore, which yielded 5,710,346 lb. of copper, 13,072,177 lb. of lead, 373,180 oz. of silver, and 10,548 oz. of gold. The total amount of exploration and development work done was 17,407 ft. At the end of 1918, the deepest workings in the mine were on the 1600-ft. level. The results of exploration work on that level indicated that in depth the Highland Boy lode, after passing through a leaner zone, which commenced at the 1300-ft. level, was again showing enrichment. Sinking was therefore resumed, and the shaft is now between the 2200 and 2400-ft. levels. The 1800 and 2000-ft. levels are being opened up and the results so far have justified expectations; particularly on the latter, where a new orebody has been cut in the Highland Boy limestone. The 2400-ft. level will be opened up during 1920. During the past year, laboratory experiments for the treatment of the copper ores by flotation, confirmed by an actual mill-run of 2500 tons, showed conclusively that a reduction in production costs can be made by milling the copper ores, which will make available a large tonnage of ore in the mine heretofore classified as too low grade to be profitable. Plans are being completed for a 1000-ton mill, which will be constructed during the coming year.

ERRERA.—Ore shipments from this district for the week ending March 27 totaled 162 cars, an increase of 13

over the previous week. The Chief Consolidated heads the list with 36 cars; Dragon Consolidated, 28; Tintie Standard, 23; Iron Blossom, 13; Grand Central, 9; Eagle & Blue Bell, 9; Centennial-Eureka, 8; Colorado, 8; Mammoth, 6; Gemina, 5; Bullion-Beck, 4; Empire Mines, 3; Victoria, 3; Sunbeam, 2; Swansea, 2; Ridge & Valley, 1; Alaska, 1; and Eureka Hill, 1.

The new No. 2 shaft at the Chief Consolidated mine is being sunk and concreted at the rate of 65 ft. per month. This work is under the direction of Walter Fitch, Jr., and the character of the ground is such that sinking and concreting has been exceptionally difficult. The shaft is one of the largest in the State and is the first to be lined with concrete from top to bottom. The shaft is now about 1200 ft. deep, and sinking will continue to the perma-

BRITISH COLUMBIA

CALUMET & ARIZONA MAKES PURCHASE.

VICTORIA. The Cornell mining claim, on Texada island, has been purchased by the Calumet & Arizona Mining Co. This property was located by W. H. Trent, of Seattle, 20 years ago, and was worked for a time and then abandoned. The Calumet company took an option on the claim two years ago, and, examination and exploration work having proved satisfactory, the purchase has been made. H. A. Morse, who represents the company, is on the ground and will start development operations.

STEWART. The winze and raise at the Forty-Nine group, the faces of which are in high-grade ore, have been

A PROSPECT IN WEST SHINING TREE DISTRICT, ONTARIO

nent water-level, which will be at about 1800 ft. below the surface.

C. C. Griggs has been for the past two weeks compiling data and collecting information pertaining to a new concentrating plant for the ores of the May Day and Uncle Sam mines. It is understood that there is a large tonnage of milling ore in both properties, and undoubtedly the old May Day mill, which was abandoned some years ago, will be rehabilitated along up-to-date lines. It is likely that the work of remodeling the mill will be undertaken soon.

Three or four different contractors have taken a turn at the sinking of the Central Standard shaft, only to throw up the job after a few weeks or a few months. Sinking is difficult on account of the water; however the flow appears to be decreasing to some extent as the shaft progresses.

At a depth of about 160 ft. some quartz, carrying silver, has been cut in the shaft of the East Tintie Coalition property. This property was recently equipped with machinery and the present plans call for a continuation of the shaft-work until a depth of 400 or 500 ft. is reached.

stopped and the men are being used to drift on the Forty-Nine vein and to drive a cross-cut toward a vein that runs parallel to it. The Salmon River Mines, Ltd., has purchased the Jitney group, which adjoins the Forty-Nine. Development work on these claims will be started as soon as the snow is off the ground. Another consignment of 300 tons of ore, valued at about \$275 per ton, has been sent to the Tacoma smelter from the Premier mine. Work on the New Alaska, on the United States side of the boundary, is progressing favorably. The tunnel has penetrated 40 ft. of good ore. Work at the property of the Indian Mines, Ltd., is to be resumed at once.

ALICE ARM.—The Silver Horde group of four claims, through which the Wolf orebody is supposed to pass, has been sold to M. P. Olsen, who will start development as soon as the weather permits. The Department of Justice, at Ottawa, has notified the Taylor Mining Co. that it must show cause why its title to the Dolly Varden mine should not be annulled. The Dolly Varden Mines Co. had until April 11 in which to appeal against the decision of the Provincial Legislature, by which the Dolly Varden mine and railway was awarded to the Taylor Mining Co., sub-

ject to the performance of certain conditions. A considerable amount of staking is being done, notwithstanding the weather conditions, and it is said that a number of claims have been staked more than once. Some confusion is likely to ensue.

HAZELTON.—A two-foot vein of milling ore has been cut by the tunnel that is being driven at the Silver Standard mine. While the presence of this vein was known from surface open-cutting, it has not hitherto been worked. Several rich stringers have been cut by the tunnel, and one of them, that is six inches wide of almost pure argentiferous galena, is being drifted on. The mill, which has been overhauled, has been re-started.

NELSON.—The Motherlode mill, owned by the Nugget Mines company, is being thoroughly overhauled. Drifts have been extended on the vein that was recently cut by the cross-cut from the Motherlode workings, and the size of the vein and character of the ore remains unchanged. The Mining Corporation of Canada has taken up its option on the Yankee Girl mine, at Ymir, and will start development operations at once. The Consolidated M. & S. Co. has received a large order for fluorite from chemical works in the State of Indiana. The machinery at the Rock Candy mine, on Lynch creek, is to be put in shape, and production will be started at once. It is expected that the mine will turn out 18 cars of fluorite per week.

DUNCAN.—A two-bucket aerial tramway is being erected at the 'Hill 60' manganese mine, at Cowichan lake. Last summer a road was made to the mine at the joint expense of the Provincial government and the mine-owners, but, owing to the steepness of the grade, it was washed out by the fall rains. The tramway will convey the ore from the mine directly to the Esquimalt and Nanaimo railway. A 25-ft. face of ore averaging 25% manganese has been opened at the mine by open-cut.

ONTARIO

COBALT PROPERTY OPTIONED.

PORCUPINE.—The Clifton-Porcupine recently shipped two tons of ore to the Temiskaming ore-testing laboratories at Cobalt, where it was found to average \$66.45 per ton. Veins cut on the 200-ft. level have proved to be well mineralized. A dividend of $\frac{2}{3}\%$ has been declared by the Dome Mines payable April 30, a similar disbursement having been made on January 15. Prior to closing down on account of the War the company paid 5% quarterly dividends, but under present conditions until a large surplus is created it is considered unlikely that dividend payments will be resumed on the former scale.

KIRKLAND LAKE.—The Bidgood has let a contract for the sinking of a 300-ft. shaft and 2000 ft. of lateral work at that depth. The Moffatt-Hall, a new company capitalized at \$3,000,000, has taken over 12 claims comprising about 500 acres in the Lebel Township section of the Kirkland Lake area. Work at the Fidelity has been for some time at a standstill owing to the breaking down of the compressor early in March. Exploration will be resumed as soon as repairs are made.

BOURKES' SIDING.—Plans for a new mill at the

Bourkes' gold mines are being prepared. It is proposed to erect a plant with a capacity of about 50 tons per day. The property is situated some 12 miles north-west of the proved gold-bearing zone of Kirkland Lake. Geological conditions are favorable and the deposition of gold is quite heavy, though occurring in narrow streaks. A system of selective mining will be followed. The Better Ole Syndicate, organized by returned soldiers, of which Bruce Bairnsfather, the cartoonist, is honorary vice-president, has taken over the P. J. Ashby claims, comprising 320 acres, $2\frac{1}{2}$ miles from Bourkes' Siding, on which five veins have been opened up and considerable trenching done. The Lake View is getting in a 5-drill compressor and other mining machinery.

WEST SHINING TREE.—The Atlas will build an amalgamating-mill for the treatment of high-grade ore. This plan was decided upon following a test of 602 lb. of ore at McGill University, which showed gold to the value of \$64.92 per ton and recovery by amalgamation at the rate of \$47.38 per ton. Owing to the cost of a cyanide-plant the company decided on building a 60-ton amalgamation-mill and saving the tailing for future treatment. The directors of the Wasipika have laid out plans for a considerable expansion of the scale of operations which will be submitted to the consideration of the shareholders.

COBALT.—According to dispatches from The Pas, the Flin-Flon property has been optioned by the Mining Corporation of Canada and W. B. Thompson, of New York. It has been agreed to spend at least \$200,000 in exploring the large sulphide deposit; and to this end mining machinery necessary to sink two shafts is being transported to the property. It is stated that William Koerner, of New York, will manage the work, and that a force of about 60 miners will be engaged as quickly as possible. Following six months or so of exploration, it is believed the importance of the deposit will be ascertained and the holders of the option can reach a decision on the question of whether or not the construction of a railway from The Pas to the property is warranted.

The promoters of the proposed Northern Light Railway announce that, provided they receive a charter to build a light narrow-gauge railway from Elk Lake to Gowganda, they are in a position to commence the work immediately, and that within a few weeks they will complete the laying of the 27 miles of steel.

On account of quotations for silver having receded about ten points during March, the Cobalt producers withheld bullion shipments. At the end of the month, when quotations advanced, shipments were resumed.

GOWGANDA.—On the Kells property in Cokhill township, ore containing around 5000 oz. silver per ton has been found at a depth of 80 ft. The vein is but two inches in width, in this respect resembling many of the high-grade veins in Cobalt, but it is running parallel to three other veins which contain medium-grade ore at the surface. The development on the Kells is attracting interest on account of the property being some 50 miles north-west from Cobalt and about 12 miles south-east from Gowganda.

CALIFORNIA

Calaveras County.—The old Sheepbranch mine, which has been under development for two years, is in shape to start production, according to H. R. Plate, who has directed the work. The present operators have sunk to the 1700-ft. level and have drifted from the 1550 and 1700-ft. points. There is a continuous stoping length of 1200 ft. The vein is five feet wide between walls, though the gold-bearing quartz will average only about $1\frac{1}{2}$ ft. The average value of the clean quartz is over \$20 per ton, but the estimated grade of the mill-feed will be about \$12. The company expects to remodel the old 20-stamp mill and add a cyanide-plant with a capacity of 100 tons per day. It is expected to have everything in readiness to commence production by July 1.

The Carson Hill company has developed its lowest level (1100-ft.) to such an extent that predictions have now

and numerous drifts. The management states that two good veins have been uncovered.

Redding. F. A. Zimmerman has bought the Easterly mine one mile west of Shasta from George Easterly. A little high-grade ore has been shipped from the Easterly, which was located only four years ago. The two-compartment shaft at the Little Nellie mine, between Keswick and Iron Mountain, has been sunk 300 ft. in three months.

Shasta County.—Development of the large deposit of copper ore recently uncovered in its Friday-Lowden property by the Mammoth Copper Co. is showing good results. It is reported that 120,000 tons of ore has already been placed in sight, with the orebody gaining strength as work advances. According to officials, the Afterthought mine and plant will remain idle until the copper situation becomes sufficiently improved. The present low price of the metal precludes production, as costs are much heavier than in former years.

UNDERWRITERS AND ADMIRALTY MILLS IN THE JOPLIN DISTRICT

given place to actual assays and over a 10-ft. width the vein averages \$56 per ton in gold. The company is shipping from 25 to 35 tons of ore daily from this point, with some of the ore running as high as \$65 per ton. Although the exact dip of the vein between the \$65 and 1100-ft. levels has not yet been determined it is estimated that there is 250 ft. of vertical stoping ground. This puts in sight a large tonnage of ore which preliminary operations have shown will average fully as rich as on the levels above. The company has made several important changes in its plant and equipment. The mill is being increased through the construction of 10 additional stamps. A cyanide-plant is under construction which will effect further saving of gold and by mid-summer capacity will have been increased to 12,000 tons per month, or approximately 150,000 tons per year. Costs are now a little over \$4.60 per ton and when operations are swinging near the capacity mark, costs should not exceed \$4.

Grass Valley.—The erection of a five-stamp mill has been decided on by the Grass Valley Boundary Co. The mine is a new enterprise, located at the western edge of Grass Valley, and considerable ore has been extracted in the course of development work. Workings comprise a 200-ft. shaft

It is declared that the process proved satisfactory and that operations will be resumed as soon as the copper market warrants.

With two shifts employed the Colma Copper Co. is driving ahead the main tunnel in exploration of the Uncle Sam group. The lateral had a length of 1500 ft. when work began and will be driven about a mile. It will explore at greater depth promising territory already prospected by drifts from the Mammoth mine. New equipment has been ordered and driving will soon be speeded up with three shifts.

MISSOURI

Joplin.—The Kitty mill, west of Cardin, that has been down about five weeks because of damage done by fire, has resumed operations and soon should be producing as well as ever. It was necessary to re-build the mill-derrick and hopper and the east end of the mill, as the original structure was destroyed by fire and dynamite used to help in extinguishing the flames. The origin of the fire has never been learned. It started in the derrick away from the electric wiring and the only theory advanced is that there was spontaneous combustion of coal-dust. In order to keep the fire

from reaching the main portions of the mill, four boxes of dynamite were exploded ahead of the fire, blowing up much of the material on which the fire was feeding. This held back the flames until a fire-company from Miami arrived.

The new mill of the Hunt Mining company is being erected rapidly on the site of the mill formerly known as the Pittsburgh-Miami, which was destroyed by fire two months ago. The new mill is being constructed of galvanized iron and is somewhat larger than the old one. The building is almost finished and some of the machinery has been placed. The Hunt Mining Co. came into possession of the property this year and within a short time the plant was operating steadily, proving to be a good producer.

MONTANA

Butte. The Davis-Baly company during March produced the largest tonnage in the company's history and a further improvement is looked for in April. New ore-bins and sorting devices are in operation. The ore is conveyed from the skip by means of a conveyor-belt with two men on each side picking waste. For each ton of waste sorted the company saves \$9, and these four men can pick out 20 tons daily, effecting a saving of approximately \$180 per day. The ore-body recently reported on the 2700-ft. level is about eight feet wide and has an estimated copper content across this width of 6%. This vein cannot be regarded as one of the objectives of the cross-cut on this level; the several fissures opened on the 2500-ft. level, for which the working is headed, will be cut within five or six weeks.

NEVADA

Eureka.—At the Eureka-Croesus ore is being extracted from the 400-ft. level and stored in the bins at the mine while the roads are blocked. It is planned to start hauling as soon as the roads become open to traffic. The face of the Eureka-King tunnel is still in the black shale, but as it has been driven now about 400 ft. in this formation, it is expected that the contact will soon be reached, when the direction of working will be turned toward the Eureka tunnel, in order to get under the high-grade orebodies that were mined in the early days. This tunnel is 550 ft. below the Eureka tunnel.

Lovlock.—A raise from the face of the lower tunnel in the Jose-Davis company's lease on the Sheepherder, 10 miles north-east of here, has broken into the shoot of high-grade ore that is being mined above the upper tunnel. The ore contains free gold and is as rich as in the other workings. Ore now going through the Gibson mill averages between \$80 and \$100 per ton.

National.—Lessees on the Buckskin-National property are said to have opened ore assaying from \$250 to \$600 in gold and silver at a depth of 380 ft. The find was made in a winze sunk 50 ft. from the 900-ft. main tunnel. A drift has been driven 28 ft. in the rich ore, exceptionally high-grade material being found in seams on the walls and it is estimated that the 10-ft. width will break \$100 per ton.

Pioche. Operations at the Black Metal company are being curtailed on account of the shortage of labor. The company is producing about 75 tons per day of lime fluxing-ore, carrying from 12 to 15 oz. silver per ton, a product in demand at the Salt Lake Valley smelters.

The main shaft of the Prince Consolidated has now reached a vertical depth of 585 ft. and better progress will be made from now on. Water is being handled satisfactorily and the flow is rapidly becoming stabilized as the fissure pockets are drained; 1400 tons is being shipped each week.

At the Virginia Louise eight underground headings are being driven. On the first level the work is confined to the intermediate drift and raises. On the third level a long exploratory drift is being run under the area exposed by the second-level drift, which will prove the ore-bearing territory exposed on the level above. On the fourth level the most noteworthy development is the improvement in the

character of the ore in the 410-ft. stope, which ore showed a marked decrease in the insoluble content with a corresponding increase in iron and manganese. Samples from the face of the drift on the fifth level assay 5% lead with a corresponding silver content.

NEW MEXICO

Socorro County.—As a result of the re-organization plans that have been approved by Judge Colin Neblett, of the United States District Court, the Socorro Mining & Milling Co. will soon discharge the receiver and resume operations. The company, whose mine and mill are at Mogollon, was a large producer of gold and silver. A year ago the company went into the hands of a receiver, when D. B. Scott, superintendent, was put in charge by the court. The plant remained in operation about 60 days on clean-up work and then was closed down. With adequate capital for development the property is expected to be profitable. This has been provided by A. W. Wallace and associates from Detroit.

Sierra County.—Chloride, once the scene of active silver mining operations, is the centre of considerable excitement resulting from the discovery of tin ore. Prospectors are busy on Turkey, Taylor, and Squaw creeks, and rich discoveries are also reported at the Bob Akes ranch on the east fork. On the Turkey creek claims a 65-ft. cross-cut tunnel has been completed and the entire length is said to be in ore. The New York owners of the claim have asked for bids on 1500 ft. of tunnel with a cross-cut every 200 ft., which will establish the extent of the deposit. At present there are no roads into the district. The nearest road is from Magdalen to the old 'V-Cross-T' ranch, now owned by the Evans brothers, and it can be traveled with heavy motor-trucks. A road can be built from this place to connect the Taylor creek mines at small expense.

OREGON

Josephine County.—The Almeda Mines, whose property is in the Galice mining district, has a crew of men at work cleaning up tunnels, cross-cut, and raises and re-timbering. The work is being done under the supervision of Harry Sordy, who took charge of the property last October. He has opened several good veins of gold-silver ore.

WASHINGTON

Republic.—J. W. C. Lanskill is operating the Quilp mine and shipping weekly 500 tons of ore to Tacoma and 100 tons to Northport. The Know Hill mine is shipping 100 tons per week to Tacoma.

Stevens County.—The Aichee Bee Silver-Lead Mining Co., in the Deer Trail district, is hauling machinery by truck from Spokane, according to H. W. Howard, manager. Some fine orebodies in the 22-ft. vein are being opened. On the foot-wall is 6½ ft. of lead ore, carrying 24% zinc, with just enough iron to make it a desirable fluxing ore. On the hanging wall is 2½ ft. of silver-lead ore that assays \$78 per ton. The entire 22 ft. returned \$43 per ton from a 200-ton mill-test. —E. L. Van Horn is taking out tungsten ore from a property he has secured on the Spokane Indian reservation, near the old Germania mine, according to reports. The ore is wolframite worth about \$7 per unit.

YUKON TERRITORY

White Horse.—Shaft-sinking has been stopped for the time being on Lookout mountain and the men are being employed in getting out ore and hauling it to Mayo landing. It is expected that several hundred tons will be delivered by the time navigation opens. All signs point to an early season, this year, and it is expected that shipping will start early in May. —Rich ore has been found at several places on Keno hill, particularly on the Yukon Gold Mining Co. and the McKay-Erickson properties. All the material for a dredge has been delivered at Hight creek and the machinery is being assembled. It will be ready for use early in the season.

Hoover Will Accept Nomination

The following telegram was sent by Mr. Hoover on March 30 to Warren Gregory, president of the Hoover Republican Club of California:

I had not wished to enter nor could I hitherto see any real public service by entering into partisan political discussion, more especially pending the clarification of the diverging views of the different groups in the parties on the great new issues. The recent developments over the Treaty stagnation in adjustment of our great economic problems, and particularly the many urgent representations that I have received as to the situation in my own State convince me that it is my duty to confirm the action that my Republican friends there have already taken without consulting me.

I understand that there is a great wish among the Republicans of California to have opportunity to express themselves in favor of the League of Nations with proper reservations safeguarding American tradition and interests, as opposed to the extreme view advocated against any League at all. I differ just as strongly with this view as I differ with the extreme position taken by the President on participation in purely European affairs. This issue is whether with reservations protecting our position, we should join the moral forces of the world to reduce the dangers again growing around us, or whether we will, by pretense of an insularity that we do not possess, sit by in the face of growing armies, navies, National antagonisms, reaction or, in reverse, the spread of Bolshevism, through much of the world. This would be the defeat of the hopes for which our sons were sacrificed in this war.

Entirely aside from this moral idealism of the League and the danger to our own ultimate peace, the solution of our domestic problems, such as the size of our armament, reduction in taxation, and the prevention of agricultural and industrial depression and consequent unemployment, is dependent upon stability abroad and upon our access to the world's markets which today are endangered by discrimination against us through our inability to exercise our veto under the Treaty. I believe it is the transcendent service which the Republican party can render to the Nation to settle a League efficiently designed to give us these National protections.

No one should be able to dictate the policies of great parties, yet every man and woman has a right to decide what issues and measures he will support. If the Republican party—with the independent element of which I am naturally affiliated—adopts a forward looking, liberal, constructive platform on the Treaty and on our economic issues and if the party proposes measures for sound business administration of the country, and is neither reactionary nor radical in its approach to our great domestic questions and is backed by men who undoubtedly assure the consummation of these policies and measures, I will give it my entire support. While I do not and will not myself seek the nomination, if it is felt that the issues necessitate it and it is demanded of me, I cannot refuse service.

HERBERT C. HOOVER.

The following telegram was sent also on March 30 by Mr. Hoover to Ralph P. Merritt, campaign manager for the Hoover Republican Club of California:

My views on the treaty situation are as follows: Regardless of what any of us may think should have been the provisions of either the League or the Treaty, we and the world should not be kept waiting longer for a settlement. The whole process of peace has been necessarily one of compromise, and so long as the final form gives us freedom of action and room for constructive development of peace I believe it should be accepted.

The reservation should satisfy the most timid as to entanglement and to put the feeling of the President and his associates that the strength of the League is somewhat uncertain. I believe that they should also accept. I do not believe that the League reservations, as recently modified, destroy the possibility of the creation of a potent organization to mitigate the danger in front of us, and the alternatives are a continuation of our state of war for another year, or the unthinkable thing for us to make a separate peace after we have gone so far as to agree on its main lines with comrades in arms.

Due to this unsettlement and other causes that the League would mitigate, the world is steadily drifting back to a worse state of international antagonism than existed before 1914. The naval strength of every great nation, except the enemy, and Russia, has been increased during the War. Many great armies have been demobilized, yet the world is again engaged in preparedness and the actual number of men under arms today is much larger than before 1914. The world's total armament and its military expenditure is larger despite the burden of grinding debt. No moderating influences can be set up until we come to a conclusion and join the League that was created at our inspiration, and upon which the entire theme of settlement, our real hope of a better world, revolves.

The President seems to feel that the foundations of the League rest upon our participating—subject to approval of Congress on use of force—in an obligation to preserve the territorial integrity and political independence of its members against aggression. Without entering upon this method of preventing aggression, I believe a great foundation of peace does lie in the continuous functioning of a body of great international representatives sitting outside the pettiness of day-to-day international relations, engaged upon conciliation, the mitigation of antagonism; the very effective boycott of disturbers through arousal of public opinion against them, and through it the immediate undertaking of disarmament of the world, to a simple defensive footing.

This war surely demonstrates that nations become aggressive largely through the permanent military class that grows out of the maintenance of large armies and navies, with all the social, political, commercial, and propaganda pressures that naturally spring up around them. Military groups in these days always go into action on the claim of self-defense, and to none of them is aggression held in check against so-called military necessity. Their view of political independence is boundaries of purely military character. Itself a basis of friction. A reduction of armament would directly lessen the influence of these groups, who are themselves the cultivators of war.

This question of disarmament is a vital issue to us. We are dependent upon our foreign trade for much of our prosperity, and the naval and military strength of the world is concentrated in fewer hands today than in 1914. If there be the League, sitting in the development of methods of peace in localization of possible conflict, I have no doubt that the great majority of the British, French, and Italian people will be themselves the first to approve of a reduction of naval and other armament; for they, too, are suffering under its burden. If we can secure no safety by disarmament we must tax ourselves a couple of billions a year and enter a race of preparedness and build up a military caste of our own. Is it not worth entering the League with the determination to at once test its value on the reduction of armament to a real defense basis within a measurable time, before we enter this race, with no goal but misery and danger?

There are other great practical issues which should be considered before we close our only door to the immediate solution of this situation. If the Treaty fails ratification now it apparently must be kept on the American stage for a year until the next administration, in which case we re-

main legally at war with Germany, or, alternatively, we must make a separate peace. If the first course is adopted, our citizens would have no right in Germany or Austria—our passports would not run there—we would have no proper equality in trade with a large portion of Europe.

We do not need to be involved in scores of treaty commissions dealing with purely European matters, yet the reparation commission is an accomplished fact, and is the most powerful economic body in the world. It is today conducting, without our veto, a control that effects our trade, not only in Europe, but many other interests highly important to us closer to home. Naturally, with us outside the Treaty, we must expect the commission to at least neglect our interests.

All of our war legislation would still continue as a ready weapon for administrative use. We must be forced to go on with our military budgets to meet the growing dangers that develop. We would be exerting no influence to mitigate the growth of the old system of antagonism and combinations.

Another alternative is that we abandon this Treaty. That is: We ask Germany to negotiate a separate peace with us. Having thus isolated ourselves from the Allies, and withdrawn any consequential army from Europe, can we suppose that Germany will accept the Versailles terms from us? Will we resume fighting again? We shall be in the position of a nation that has abandoned its allies after having made an agreement with them for the main lines of the Treaty as distinguished from the League provisions, which are not challenged even by reservations.

Will not the Germans thus effectually drive a cleavage between us and the Allies? As the reparation commission can effectually veto any settlement we make with Germany for civilian losses, alien property, and trade matters, shall we go to the Allies and ask their help? Some of the terms of the Versailles treaty may be proving impractical, but instead of sitting with our associates in friendly effort to develop such changes as may be demonstrated as necessary, are we, at Germany's and Austria's insistence as equals in the new negotiations, to admit changes in these provisions that will create antagonism of all the Allies?

In my view, the soul of the League as an influence to the prevention of war, may have died in world antagonism, long before we can come to our Presidential election. The League is not a document—it is an organization of the moral sense of the civilized states. Without their combined goodwill it can never succeed. In any event, the League is, of course, already in actual being among the other members. It cannot, however, become a real beneficent force, unless it contains the support of all the great powers; and this can only come about by our entrance. With us out, it is in great danger of developing into an organization for the advancement of certain national interests; and we may find it an economic, if not a political league against us, for we are the creditors of the world today. The adherence to it of other countries in the Western hemisphere, may direct their political perspective to Europe, instead of to the United States, and a cleavage may be driven in the bond for peace that we have striven to establish in this hemisphere.

Are any of these alternatives better to anyone than acceptance of the Treaty as passed by the majority of the Senate? Is it not the practical thing to ratify it, and then to build constructively toward peace and goodwill? If the League proves a success the world will readily grant it greater powers. All these are the issues of self-interest. There are greater issues than these. Two years ago when the entire world was aligned against Germany, our prayer was that we might be fighting the last great war—that something better should come to the world in return for the sacrifice. Today, the world is drifting back, and through our failure. Victory may turn to new antagonisms.

HERBERT C. HOOVER

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. W. Whitley is at San Diego, California.

H. V. Burgard, of Denver, was in San Francisco last week.

Luther B. Eames has returned to Denver after a short stay here.

T. A. Rickard attended the International Mining Convention at Seattle.

Edward E. Free, chemical engineer, of Baltimore, was here this week.

Francis Webb, of Denver, sails from New York for England on April 17.

Abbott A. Hanks was at Seattle this week, attending the Mining Convention.

S. J. Lewis is erecting a mill on his mine at Zacualpan, in the State of Mexico.

Charles Bocking, manager for the Butte & Superior Mining Co., is in New York.

Stanley A. Easton, manager of the Bunker Hill, is taking a short holiday at Del Monte, California.

D. D. Moffat has returned to his headquarters at Salt Lake City, after a trip to Duluth and Chicago.

C. W. Adams, manager of the East Helena plant of the A. S. & R. Co., has been in Utah recently.

H. A. Guess, of the A. S. & R. Co., has been in Utah recently, visiting the company's properties there.

Harry J. Wolf has resumed general practice as mining engineer with offices at 42 Broadway, New York.

Alexander S. Prosky, president of the Seminole Regent and Argentine-Divide companies, is here from Reno.

S. F. Taylor, of New York, president of the Como Consolidated Mining Co., was in San Francisco for a few days last week.

Marcus Lobt, of Toronto, representing the Canadian Royal Mining & Operation Co., is visiting mining and metallurgical plants in Utah.

W. D. Leonard, assistant manager of the Colorado Department of the A. S. & R. Co., was a visitor at the company's Utah plants recently.

C. G. Rice, of Boston, has been elected president of the U. S. Smelting, Refining & Mining Co., to fill the vacancy caused by the death of William G. Sharp last July.

S. M. Soupeoff, mining engineer with the Utah Department of the A. S. & R. Co., has returned to Salt Lake City after an inspection trip to the Nacozari district, Mexico.

Frederick R. Weekes, of New York, and J. J. Stubenford, of Long Beach, California, have been making an examination of the Naildriver mine at Park City, Utah, for Eastern interests.

A. C. Boyle, Jr., Professor of Mining and Metallurgy at the University of Wyoming, accompanied by a party of ten students, has been visiting mines and metallurgical plants in Utah.

Richard Roberts died at his own home in Wales on March 19. He was expecting to return to Wardner, Idaho, where he lived for 25 years. 'Uncle Dicky' was well known and highly regarded in the Coeur d'Alene. For 30 years he worked in the Bunker Hill mine and was always one of the best of that company's employees. In later years he was successful in a lease on the west branch of the Reed tunnel, where he was operating, through his associates, at the time of his death. He was an honest worker, a good citizen, and a loyal friend.

EASTERN METAL MARKET

(By wire from New York)

April 5.—Copper is quiet and strong. Lead is dull and firmer. Zinc is inactive but steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 40.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

REVISION OF FEDERAL TAXATION

Secretary Houston, of the Treasury Department, has recommended measures for the simplification of income and excess profit taxes. He is quoted as saying:

Complexities in tax laws violate the most fundamental canon of taxation, that the liability shall be certain and definite. It is not merely a source of irritation, labor, and expense to the taxpayer, but when conjoined, as it is in the present law, with the heavy rates of taxation which war exigency has forced upon us, it becomes a menace, threatening enterprise with heavy potential back-taxes which all the taxpayer with dread, creating, to be sure, an attractive source of additional revenue, but clogging the administrative machinery and threatening indeed its breakdown.

Final determination and settlement of tax claims and assessments—I recommend therefore as the most urgent and important of the measures of simplification which could advantageously be put into effect at once, an amendment authorizing the Commissioner of Internal Revenue, with the consent of the taxpayer and the approval of the Secretary of the Treasury (or under such other public safeguards as the Congress may prefer), to make a final determination and settlement of any tax claim or assessment, which shall not thereafter be reopened by the Government or modified or set aside by any officer, employee, or court of the United States, except upon a showing of fraud, malfeasance, or misrepresentation of fact materially affecting the determination thus made.

This recommendation is of major importance. At present the taxpayer never knows when he is through. Every time an old ruling is changed by court decision, opinion of the Attorney-General, or re-consideration by the department, the department feels bound to apply the new ruling to past transactions. The necessity of constantly correcting old returns and settlements is as distressing to the department as it is obnoxious to the taxpayer.

Interpretive regulations or Treasury decisions not to be retroactive—as a desirable concomitant of the preceding suggestion and for reasons stated in explaining that suggestion, I recommend the adoption of an amendment providing in substance that in case of a regulation or Treasury decision made by the Commissioner or the Secretary or by the Commissioner with the approval of the Secretary is reversed by the subsequent issue of a similar regulation or decision, and such reversal is not immediately caused by the action of the Attorney-General or a decision of a court or based upon an opinion of the Attorney-General, such new regulation or decision may be made effective from the date of approval.

Five-year limitation on time for bringing suit for collection of taxes.—Section 250 of the Revenue Act of 1910 now provides, in sub-division (d) that no suit or proceeding for the collection of any tax shall be begun after the expiration of five years after the date when the return was due or was made or except in the case of false or fraudulent returns with intent to evade the tax. This subdivision has been held to apply only to taxes due under the revenue act of 1918. I recommend that this time limit be extended to all income and profits taxes due either under present or prior acts of Congress.

MONEY AND EXCHANGE

Foreign quotations on April 6 are as follows:

Sterling, dollars: Cable	4.6315
" Demand	4.6274
Francs, cents: Cable	4.90
" Demand	4.89
Lire, cents: Demand	4.87
Marks, cents: Demand	1.00

Eastern Metal Market

New York, March 31.

The markets are nearly all more active and stronger with a better demand in most of them.

Buying of copper is heavy and prices are higher and advancing.

There is much more activity in tin and buying by consumers has been and is a feature.

The lead market is quiet and easier with prices fairly steady.

Demand for zinc is very light but values are fairly steady. Antimony is quiet and unchanged.

IRON AND STEEL

Predictions of easier conditions in steel products continue, due in part to the volume of business booked at the Steel Corporation prices and in part to prospects for larger output and faster shipments, says "The Iron Age". Yet current buying and selling show no reduction of the higher prices recently paid in ordinary transactions with independent mills.

The higher coke prices predicted in view of the release of Government control April 1 are already a fact. Blast-furnace coke has sold at \$19, one such contract as of April 1 calling for 15,000 tons in the second quarter, and as high as \$12 has been paid for prompt coke. Higher pig-iron, because of higher coke and higher freight rates, is the prediction of sellers.

Signs are that the steel producers will take some of the notes of the railroads in payment for car-building material, just as the car-builders themselves have at other times accepted negotiable car-trust certificates.

COPPER

Interest in copper is growing. Buying particularly by domestic consumers has been and is heavy and prices are higher. The predicted buying movement is apparently on and the tone of the market is strong. Electrolytic copper is quoted and being sold by the large producers at 19c., New York, for early delivery with Lake copper at 19.25c., New York. For June a slight premium is obtained in some cases. Export business is much better, also at premium prices over domestic sales. Twenty-cent copper is predicted for the near future. There is a disposition to decline third-quarter business, so confident are sellers of a rising market. The recent statement of the head of the Export Association has had a stimulating effect. The plans for the formation of a revolving fund to finance foreign buying are nearer fruition.

LEAD

The market is quiet and steady. Lead which has been held up in transit is moving more freely into consumption, rendering the entire situation easier. The leading interest still maintains its quotation at 9c., St. Louis, or 9.25c., New York, for early delivery and there has been no material change in the outside market. We quote for early delivery in wholesale lots at 8.75c., St. Louis, or 9c., New York, with demand fair and consumption still heavy. The present easier conditions are believed by one large seller to be only temporary as production has not improved enough to maintain supplies equal to ultimate demand.

TIN

The market is in more normal condition in that it is now largely in the hands of importers and less under the control of dealers and speculators. Demand from consumers is also heavier and gaining in volume. From March 23 to 27 buying was large, averaging 250 tons or more each day, mostly for nearby position. A good business in futures was also done.

On Monday business was done at from 62.50 to 63c., New

York; on Tuesday at 63.75c. More could have been sold but supplies are evidently concentrated in strong hands who are unwilling to part with all their metal at once. Yesterday spot Straits was sold at an average of 63.75c., New York, against an average of 62.62½c. on Monday, the higher values were due to an advance in the London market of £13 to £14 per ton, spot Straits being quoted there at £359 55s. per ton. Arrivals to date this month have been 4175 tons, of which only 180 tons came in at Pacific ports. The quantity afloat is 2215 tons. Besides 50 tons exported this month to Germany there has been 15 tons sent to Japan.

ZINC

The week has been a very quiet one in this market. Not much business is reported as transacted. Prices have been less erratic than a week ago although they have followed to a large extent the fluctuations in the London market and the changes in the pound sterling. Export demand is now light and domestic buying is only fair. On the dips there have been fair purchases of prime Western. In view of the heavier demand for copper, buying of brass-special metal is expected to develop. For early delivery and shipment into the third quarter, prime Western is obtainable and has been sold today at 8.50c., St. Louis, or 8.85c., New York.

ANTIMONY

The market is quiet and unchanged with wholesale lots for early delivery held at 11.50c., New York, duty paid.

ALUMINUM

Virgin metal, 98 to 99% pure, is obtainable at 33c., New York, from the leading interest and at 31c., New York from the outside market.

ORES

Tungsten: The tariff matter is the all-absorbing topic now and business in the meantime is in check. There is less opposition to the measure among certain interests than there was, but opinion is divided as to whether any tariff will be passed. Quotations are nominal at \$6.50 to \$15 per unit, depending on the grade of the ore and the delivery.

Ferro-tungsten and tungsten powder are obtainable at anywhere from 90c. to \$1.15 per lb. of contained tungsten.

Molybdenum: The market is quiet and prices are nominal at 75c. per lb. of MoS₃ in regular concentrates.

Manganese: Imports of high-grade ore in February were only 4106 gross tons, or the lowest for any month since early in 1915. These data came with a startling effect on the present tight situation in the entire manganese market. Foreign ore for early delivery has sold in the last few days at 80c. per unit, seaboard, in lots up to 600 tons, and other quantities of Indian ore are under negotiation. There is also available some high-grade Chilean and Java ore. Prices vary from 65 to 80c. per unit, depending on the delivery and quantity. Of decided interest is the sale of 15,000 to 20,000 tons of Indian ore to a large American producer of ferro-manganese for delivery over the year commencing in June.

Manganese-Iron Alloys: American makers of ferro-manganese have advanced prices from \$180 a week ago to \$200, delivered, sales being recorded at both levels. For spot delivery a limited amount is offered at \$250, delivered. Almost no British alloy is available now for any delivery and two British producers will have to delay shipments on contracts because of an unexpected shortage of ore in Great Britain. Spiegeleisen is active and higher at \$62, furnace. There have been sales of about 4000 tons for domestic and foreign account.

Ferro-manganese imports in February were 2939 tons against 2771 tons in January and 2752 tons per month in 1919.

Company Reports

BARNES-KING DEVELOPMENT CO.

Report for the year ending December 31, 1919

Property: mines at Kendall, Forsyth county, Montana; also a working option on the Piegan-Gloster mine at Marysville, Montana

Operating Officials: George T. McGee, manager; J. H. McCormick and T. W. Heatherley, mine superintendents.

Financial Statement: during the period, March 1 to December 31, total bullion returns were \$4,179,533; miscellaneous income, \$127,289; total expenditures, including development on new properties in British Columbia, California, Nevada, and Idaho, amounted to \$4,445,584; funds available December 31 were \$75,842, in addition to \$50,000 in liberty bonds.

Dividends: \$120,000 was disbursed, making the total to date \$420,000.

Development: \$65,000 was spent in development of the Piegan-Gloster mine with disappointing results. None of the properties being developed under option are deemed worthy of purchase.

Production: the North Moccasin mine produced 25,843 tons valued at \$6.56 per ton, the Piegan-Gloster 11,917 tons at \$6.27 per ton, and the Shannon 36,740 tons at \$10.75 per ton.

DALY WEST MINING CO.

Report for the year ending December 31, 1919

Property: mine and mill at Park City, Utah.

Operating Officials: G. W. Lambourne, general manager; O. N. Friendly, general superintendent; G. R. McKay, mine superintendent.

Financial Statement: proceeds from ore sales, \$179,910; sundry receipts, \$14,648; capital stock increase, \$140,000; total income, \$334,557. Mining cost, \$72,890; prospecting and development, \$87,597; total expense, \$216,205.

Dividends: none for past seven years. Total to date, \$6,606,000.

Development: 4928 ft. of exploratory work, from both Daly West and Judge workings, was done. No definitely important discoveries were made but indications are favorable.

Production: 3242 tons of ore on company account; 1546 from lessees and 1247 tons of concentrate and tailing were marketed. Company ore averaged \$34.97, while the other products averaged \$22. The mill was inoperative.

UNITED VERDE EXTENSION MINING CO.

Report for the year ending December 31, 1919.

Property: mine and smelter at Jerome, Arizona.

Operating Officials: George Kingdon, general manager; George W. Nicolson, general superintendent; James Heggie, smelter superintendent.

Financial Statement: gross revenue from metals produced, \$5,058,669; other revenue, \$406,256; total, \$5,464,924. Operating expense, \$2,771,592; miscellaneous expense, including taxes, \$569,309; written off to reserves for depletion and depreciation, \$2,359,180; total, \$5,700,080. Net loss to surplus, \$235,156.

Dividends: four quarterly dividends; total, \$2,362,500; total to date, \$11,130,000.

Development: 5578 ft. of development work included 167 ft. in the Edith shaft and 1233 ft. of haulage ways. The sump and pump-station below the 1700-ft. level has been completed. The estimated ore-reserves amount to 571,400 tons, averaging 15% copper, 0.025 oz. gold, and 3.0 oz. silver per ton.

Production: 96,546 tons of ore yielded 28,860,615 lb. of copper; the average selling price was 17.163c. per pound. The smelter was closed for four months during the year on account of a labor strike in the district. Costs were as fol-

lows: mining, 0.943c. per pound, smelting, 0.025c. per pound; freight on ore, 0.002c. per pound; freight on bullion and refining, 0.026c. per pound; outside expenses, 0.002c. per pound; total, 0.998c. per pound.

HECLA MINING CO.

Report for the year ending December 31, 1919

Property: mine and mill at Burke, Idaho

Operating Official: James E. McCarthy, general manager.

Financial Statement: ore sales (net receipts), \$1,617,230; interest, \$73,729; rents, \$1166; miscellaneous, \$345; total, \$1,692,721. Mining and development, \$599,194; ore sorting, \$41,819; ore hauling, \$20,353; milling, \$97,099; miscellaneous, \$171,643; total, \$869,333. Net income, \$759,632; depreciation of ore-reserves, \$133,092; net profit, \$626,539.

Dividends: for the year, \$600,000; total to date, \$7,855,000.

Development: consisted of 4419 ft. of drifts, cross-cuts, and raises. The principal piece of development for the year was done on the 2000-ft. level. In December the ore on this level was encountered at approximately the same point at which it was found on the level above (1600-ft. level). The quantity and quality of the ore is good and the development so far is in every way satisfactory. Ore-reserves are estimated at 1,549,833 tons without including any tonnage between 2000 and 1600-ft. levels.

Production: tons milled, 175,102; tons of crude ore shipped 7452; lead produced, 24,726,015 lb.; silver produced 795,058 oz.

THE MASS CONSOLIDATED MINING CO.

Report for the year ending December 31, 1919.

Property: mines in Ontonagon county, Michigan, and mill at Keweenaw Bay.

Operating Officials: Elton W. Walker, superintendent; E. Fenner Douglass, mill superintendent; A. P. Bennetts, mine superintendent.

Financial Statement: gross income, \$429,845, including 1,626,973 lb. of copper on hand inventoried at 19c. Expenditures for mining were \$488,045, and miscellaneous expenses were \$87,906. Cash assets on hand December 31, 1919, amounted to \$149,667.

Dividends: no dividends during 1919; total to date, \$500,000.

Development: 2404 ft. of development work was performed during the year and the ore-reserves are estimated to be as good if not better than at the end of 1918.

Production: operations were hindered by an inadequate supply of labor; 171,474 tons of ore was hoisted, 123,780 tons was milled, and 1,963,178 lb. of refined copper was produced. Cost of refined copper, exclusive of depreciation, depletion, and construction, was 27.83c. Average grade of ore milled was 24.2 lb. per ton.

GOLDFIELD CONSOLIDATED MINES CO.

Report for the year ending December 31, 1919.

Property: mines and mill at Goldfield, Nevada.

Operating Official: E. A. Julian, general manager.

Financial Statement: proceeds from the sale of bullion and by-products, \$170,142; received as royalties, \$41,292; total, \$211,433. Other income in excess of sum paid for ore, \$33,416; operating expense, \$109,433; \$350,000 on Aurora mine loan was written off during the year.

Dividends: No. 25 amounted to \$177,957, making a total of \$29,177,789.

Development: Goldfield Consolidated Mines Exploration Co., a subsidiary of the Goldfield Con. Mines Co., is developing various properties with a view to possible purchase.

Production: milling operations were finished in January; followed by a thorough clean-up of the plant, producing the income as given in the financial statement.

Book Reviews

Water Powers of British Columbia. By Arthur V. White. Pp. 620. Ill. index. The Canadian Commission of Conservation, Ottawa, Canada.

This report is a compendium of data relating to the water-power resources of British Columbia. The opening chapters discuss the general principles governing the conservation of inland waters. Then follows a historical survey of water legislation in British Columbia. Lists are then given showing the various possibilities of power development, followed by tables of stream-flow and meteorological and other hydrometric records. The volume closes with a bibliography.

Manufacture and Uses of Alloy Steels. By Henry D. Hibbard. Pp. 92. Index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$1.25.

This is a reprint of a monograph recently issued by the U. S. Bureau of Mines. After a general introductory chapter, the author considers in succession the principal kinds of alloy-steels, and gives a brief summary of the methods of manufacture, characteristic properties, and principal uses of each one, accompanied by a bibliography. While the treatment is so brief that occasional omissions of important facts are inevitable, the book should prove of value to anyone interested in the subject.

Hydrology. By Daniel W. Mead. Pp. 626. Ill. index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

In this volume, Professor Mead has increased the debt that the hydraulic engineers of America, and for that matter of the whole world, owe to him. Every aspect of the subject is discussed thoroughly and each chapter closes with a reasonably complete bibliography for the use of the engineer that wishes to pursue his studies further. The various meteorological factors affecting rainfall are discussed in turn, and this is followed by a consideration of the factors affecting runoff, with particular attention to the conditions producing floods on the one hand or drought on the other. The book is well-illustrated with photographs, maps, and diagrams. It will prove indispensable to the hydraulic engineer.

Timber: Its Strength, Seasoning, and Grading. By Harold S. Betts. Pp. 223. Ill. (together with several insert maps and charts), index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

The title of this book should rather have been 'Timber in the United States', since it is devoted entirely to this country. The author is a member of the staff of the U. S. Forest Service, and has made liberal use of bulletins of the Service, both by himself and by co-workers. The book, however, is not a mere compilation, but an excellent short treatise on the subjects mentioned in the title. An interesting feature of the book is a description, illustrated by sketches, of the standard method for making the various tests of the properties of timber, including many tests that are not familiar to most engineers. It is interesting to note that the alarmist note sounded by many so-called forestry experts, particularly a decade or two ago, is absent in the present volume. The author frankly recognizes that, while the timber consumption and waste at the present time is considerably in excess of the replacement, there is every reason to suppose that substitution of other products, reduction of waste, etc., as well as reforestation, will change this condition before any actual timber famine occurs. Besides an introductory and a final chapter, both of them mainly statistical, the chapter-headings are: Strength of Wood, Effect of Moisture and of Preservative Treatments on the Strength of Wood, Strength of

Wooden Products, Seasoning of Wood, and the Grading of Lumber. The treatment is non-technical and entirely intelligible to the layman. It should be of value both to the user and the manufacturer of timber.

Prospecting for Oil and Gas. By L. S. Panyity. Pp. 244, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.25.

The first ten chapters of this book, comprising 134 pages in all, deal directly with the subject indicated by the title, and they are by far the most useful part of the volume. These chapters comprise a general discussion of the geological factors affecting the accumulation of oil, methods of surveying, and doing the other necessary field work. The treatment is necessarily brief but not so brief as to fall of being useful. The remainder of the principal part of the book is disappointing. It attempts to cover so much that it covers nothing at all. 'Scouting' is discussed in a chapter of 3 pages, and a total of 67 pages is devoted to Methods of Locating Wells, Drilling Methods, 'Bringing-in' Wells, Completion of Wells, Gauging Oil and Gas Wells, Increasing Production, and The Producer and Landowner. The result is that the treatment is so fragmentary that, for instance, the chapter on drilling methods does not even mention the use of cement for shutting off water. This latter part of the book had far better have been omitted and the space devoted to additional matter regarding the subjects treated in the rest of the volume. The appendix contains typical 'geological columns' in several oilfields and some mathematical tables.

Employment Psychology. By Henry C. Link. Pp. 435. Ill. index. The Macmillan Co., New York. For sale by Mining and Scientific Press. Price, \$2.50.

The psychologist just now is receiving the attention in the industrial world that was given to the efficiency expert a few years ago. Both have suffered because of the men that, after acquiring a smattering, posed as experts, and have suffered also because part, at least, of the general public has expected entirely too much from their work. If any reader of the present volume expects unduly important results from the work of the psychologist, it will not be the fault of the author, who is ever on the alert to point out the limitations of psychological methods not only in the hands of a novice, but even when used by an expert. On the other hand, he shows that carefully selected psychological tests and records can be made of great value, not only in hiring employees, but also in transferring, and even in 'firing', when that becomes necessary. The material in the book is based mainly on actual experience with the workers in industrial concerns. Part I is devoted to psychological tests describing the tests used and the results obtained in selecting both men and women for various kinds of factory and office work. Special stress is laid on the importance of snitting the test to the particular kind. In discussing the scope of psychological tests, the author gives his reasons for believing that tests cannot be developed that will be of service in selecting men for the higher executive positions. Part II deals with trade tests and other applications of employment psychology, and considers such subjects as the proper methods to be used by an employment manager in questioning an applicant, the analysis of jobs, and the field of the so-called vestibule school. Part III discusses selection and retention of employees, while Part IV gives the author's general conclusions regarding the application of psychology to employment problems, considered from the point of view of both the employer and the employee. The appendix describes several of the most commonly used tests as well as the methods to be used for rating the results. The book should be in the hands of employment managers and employers generally.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE SULLIVAN DRILL-STEEL FURNACE FOR OIL OR GAS FUEL

The efficient sharpening and tempering of drill steel has come to be recognized by mine operators as well as by drill manufacturers, as being an important factor in the success and low cost of rock excavation; and during the past few years, much has been done to improve drill-bits and drill-steel, in these respects. Since the introduction of mechanical

furnace at once, but it is recommended that only one side be used, as best results are obtained from this practice. An adjustable support carries the outer ends of the steels while in the furnace. The ends of the steels to be heated extend over the combustion-chamber, supported on the adjustable hearth, and abut against a movable stop of fire-brick. About twenty 1½-in. bits may be placed in the furnace from one side, at one time.

The following features and advantages of the Sullivan furnace will be noted by those who have had experience with coal or coke forges and with other types of oil or gas furnaces.

(1) Uniform temperatures are secured without danger of overheating or burring. (2) Great capacity. (3) Economy of fuel and compressed air. (4) Adaptability to different kinds of fuel. (5) Flexibility, providing for adjustment to heat any portion of the steel desired. (6) Ease of adjustment and repair. (7) Low cost of maintenance.

When coal or coke is used in a forge, the maintenance of a uniform temperature over any considerable period is difficult, whereas with the oil or gas-furnace, with proper feeding and atomizing equipment, this becomes a simple matter. The Sullivan furnace is equipped with a burner for gas or an atomizer for oil, having pipe connections for compressed air and fuel. By proper regulation of the valves, a suitable mixture and quantity are obtained to secure a flame of the proper volume and intensity. When this regulation has been made, this part of the operation becomes almost automatic and requires little or no attention on the part of the

operator, until a change of temperature for some other purpose is desired. By means of a suitable pyrometer, the purchase of which is always recommended as a part of the furnace equipment, the operator can maintain the temperature in the furnace at the proper maximum at all times, avoiding any danger of overheating the steel and thus burning and destroying the cutting and wear-resistant qualities of the bits. The importance of this feature cannot be emphasized too greatly.

Using one side of the furnace only, two Sullivan machines can be kept supplied with steel at forging temperature, by this new furnace. This means that a steel is taken from the furnace every 30 seconds. Still greater capacity can be secured, if the sharpeners are working on dull bits and not on new stock only, by heating from both sides of the furnace. This procedure would also be recommended if the two sharpeners are handling different kinds of steel. For instance, if one machine is sharpening cruciform stoper-bits, while the other is handling hexagonal or round hollow steel, the ability to work from both sides of the furnace, with the slight necessary increase in fuel consumption, is very valuable.

As will be noted from the above description, only sufficient fuel need be burned to produce the necessary maximum temperature. The combustion-chamber is so shaped, and the position and operation of the hearths above it, are such that every particle of heat generated is utilized for productive

Fig. 1. Drill-Steel Furnace

Fig. 2. Sectional View of the Furnace

drill-sharpeners there has been a demand for a steel-heating furnace, capable of supplying the necessary number of correctly heated steels, for machines of large capacity.

The Sullivan drill-steel furnace, shown in Fig. 1, consists of a rectangular cast-iron box, with a lining of fire-brick, having adjustable hearths and hoods, with a burner or atomizer attached at one end. The furnace is mounted on four legs, at a convenient working height. It is so designed that steels may be inserted from either or both sides of the

work. The fire-brick lining absorbs a large proportion of the heat, and this is given off in reflected form with consequent economy of heat.

As stated, compressed air is used for atomizing the oil-fuel, and this is taken from the high-pressure supply-line, on which a reducing valve is placed, to provide air at a pressure of from one to five pounds, as required by the character of the fuel. The arrangement of the valves on the burner is such as to permit very close regulation, and no more air should be admitted than is actually required to produce complete combustion. The use of more air than this produces an oxidizing flame, causing the steel to blister or scale, and subjecting the lining of the furnace to undue wear. The oil and air-valves should be opened only sufficiently to maintain the heat required. Wider opening merely results in waste of fuel. Records carefully kept over a long period indicate that the normal fuel-oil consumption of this furnace is from 16 to 18 gallons per day of 8 hours, or approximately two gallons per hour.

The burner or atomizer employed is designed to handle gas or fuel and crude-oils of 20 B. or lighter specific gravity, without preheating. Heavier oils should be preheated, to assure a proper rate of flow to the burner. When oil is used, a compressed-air blast at low pressure is employed to atomize it.

Surmounting the combustion-chamber, which consists of an opening lined with fire-brick about three feet long, six inches wide, and seven inches deep, are two adjustable hearths, illustrated in detail in Fig. 2. These are formed by cast-iron brackets, containing a row of fire-brick. These hearths can be moved in or out to reduce or to widen the opening above the combustion-chamber, and in connection with the adjustable stop, permit the heat to be concentrated at the tip end of the steel for tempering purposes, over several inches of steel for making bits, or at any desired point on the steel, as in making shanks. The adjustable stop, formed of an iron holder containing fire-brick, is bolted on top of the hearth, and can be moved back and forward on it. This performs two functions, first to give an additional range of adjustability in heating the drill-steel at the proper point and in the proper length, and second, to form a rest or abutment in such a manner that the entire face of the bit as well as the side of the steel is heated thoroughly and evenly. It will be noticed from the illustration that the bricks in this stop are tilted so that only one edge or wing of the steel comes in contact with them.

As will be seen from the illustrations, the furnace is exceedingly simple in construction, and adjustments and repairs are readily made when necessary. The fire-brick in the hoods and hearths, and in the adjustable stops are held in place by screws and when replacements are needed these are made by loosening the screws and inserting the appropriate new brick.

The fire-brick lining is practically the only part of the apparatus requiring renewal, and as standard fire-brick are employed for this purpose, it is possible for the owner to secure and maintain a supply from his local dealer, without going to the expense and delay of securing special brick or linings from manufacturers. The use of carborundum bricks of standard size, which may be employed for the hearths, if desired, provides additional durability. Combustion takes place over the entire length of the combustion chamber of the furnace. The so-called cold end is that next the burner, and the hot or finishing end is that farthest from the burner. All steels are replaced in the furnace next to the burner, and are gradually moved toward the opposite end, in which the finishing temperature is maintained at a constant point, and from which the steels are removed to be taken to the tempering tank or the drill-sharpener. In this way, the steels are removed from the furnace on the 'rising heat', as soon as they are ready for use.

THE COST-PLUS METHOD

Westinghouse, Church, Kerr & Co., engineers and constructors, have for 20 years operated exclusively on the cost-plus basis. They argue that this method when properly used is the fairest to both builder and client. A manufacturer is taking contracts for his product at a price to be determined on delivery of the goods. With all the comparative certainty of overhead charges, quantity production, and other predetermined costs he is unable to set a price because of the uncertainty of the labor and material markets.

And yet some people expect an engineer and builder to guarantee the cost of a building—a made-to-order product, special, individualized, never before built. If the manufacturer is unable to set a price on his product is it reasonable to ask the constructor to guarantee the cost of his?

The company's advice to prospective clients follows:

"If you are planning work, pick out several organizations which you think to be qualified, compare them on the basis of record, experience, integrity, financial strength, methods and organization personnel, and give the work on cost-plus-a-fee to the company which can best satisfy you. Your interests are identical with his and his future is measured by the record he can make for you. He depends very largely on repeat orders from old clients and he can only get them by delivering a real service. This service means more than the production of just a building; it includes economical design—both as to first cost and cost of maintenance; speed of construction—for the sooner a new plant is put to work, the sooner it will be a producer; superintendence—of the driving, result-getting type; right purchasing; close follow-up of shipments and other facts entering into a building operation.

"And further—when you are selecting your engineer and builder for cost-plus work the size of the fee of itself may tend to influence you. But look deeper. The high fee of one organization may be a better buy than the lower fee of another, not only because of a possible different definition of costs on which the fee is computed but because of an essential operating efficiency—obtainable through long experience in cost-plus work—which the former company may have over the others. In other words the company asking the larger fee may be able to do the work at less total cost. Total cost is the important factor, not size of fee. We have in the past from time to time encountered those who had had unfortunate experiences with cost-plus builders. And it always developed that it was the fault not of the method but of the constructor using the method. Successful cost-plus work hinges upon the integrity and ability of the builder. Choose him with the greatest care. Search his record and experience. Study his definition of costs. Find out his percentage of repeat orders from old clients—an unfailing indication of service rendered. Meet his officers and principal engineers, and when you are thoroughly satisfied put yourself in his hands."

In 'Graphite', published by the Joseph Dixon Crucible Co., appears the following advice on the treatment of belts: "As a belt depends entirely on its power of adhesion to the pulleys to perform its function, see to it that its power of adhesion is maintained at the maximum by not overloading, and by the consistent use of suitable belt-dressing, sparingly but regularly applied. Do not allow the dressing to clog on the pulleys. As belt-slip is an insidious danger—it makes no noise—and may be going on unsuspected until irretrievable damage has been done to the belt, begin the application of belt-dressing immediately the belt is put in use. There are several good dressings on the market, but Dixon's solid belt-dressing has no superior. For preserving the life and pliability of heavy leather belts use Dixon's paste belt-dressing. Write for free booklet No. 190-O, 'The Proper Care of Belts'."

T. A. RICKARD, - - - Editor

THE production and distribution of agricultural products is vital to our national welfare. If you want to know what the present problems are, to understand the dangers that surround the industry, to see the relations it bears to other industries; if you want the keenest analysis of essentials, and the most common-sense solution from the best informed, straightest thinking, and farthest seeing man in the world today, read the leading article in the 'Saturday Evening Post' of April 10, 'Some Notes on Agricultural Readjustment and the High Cost of Living' by Herbert Hoover.

REGULATIONS for the prospecting and leasing of coal lands under the recently passed Mineral Land Leasing Act have been announced. Any qualified person or corporation is entitled to lease not more than one tract of 2560 acres in a particular State, and competitive bidding will determine the allocation in the event of two applications for lease of the same tract. A minimum royalty of five cents per ton is provided. Permits may be granted applicants to prospect undeveloped lands, with the provision that the prospector may subsequently lease the tract at a royalty to be fixed by the Government, through the Secretary of the Interior, who is the administrator under the law. Exception is made of coal deposits in Alaska, the National parks, the Appalachian forest-reserve, and the military and naval reservations.

ALARGE proportion of the many ventures in graphite mining in the United States have been unsuccessful. Conspicuous among the few fortunate enterprises is that of the American Graphite Company, whose operations in the vicinity of Ticonderoga, New York, are described on another page by Mr. C. E. Chaffin, a member of the staff of the General Engineering Company. The difficulty generally has been the problem of concentrating the ore, and inability to do this successfully accounts for most of the failures. The separation is an art involving delicate manipulation. Minute variations in the physical and mineralogic characteristics of the ore necessitate changes in the scheme of concentration; in fact two apparently identical ores may require entirely different handling, and quite frequently the treatment of one of them has proved too much of a problem for the millman. Graphite has a specific gravity of only 2.15, so that the familiar processes of concentrating metalliferous ores are obviously reversed in that the heavy mineral is discarded

and the light saved. Micaceous minerals on account of their flaky nature are particularly aggravating, as they naturally tend to float off with the graphite. Moreover, the problem is not simply to obtain the highest extraction of graphitic carbon, but rather to recover a maximum proportion in the form of high-grade, large size flake. This is the material suitable for the manufacture of crucibles to be used in steel-plants, brass-foundries, and similar industries, and being the product most in demand brings by far the higher price. Several methods of concentration were formerly in vogue. 'Surface-tension' washers of various types; shallow circular buddles in which the ground ore was separated into distinct zones with the concentrate at the periphery; dry pneumatic concentrators; and electrostatic separators were used with varying degrees of success. However, the development of froth flotation and the scientific application of the process to the treatment of graphite ore has displaced most of the former methods.

IN this issue we give our readers some excerpts from Mr. E. T. McCarthy's reminiscences, as published recently in his most interesting book. To them we have added a few humorous sketches. It will be noted that our artist has not the pleasure of Mr. McCarthy's acquaintance nor has he seen that author's photograph, which hangs in our editorial sanctum; otherwise he would not have taken such dreadful liberties with his face and figure! The remarkable specimens of natural history that Mr. McCarthy saw in the course of his travels will provoke keen interest, coming as they do from a man with so little of the Munchausen about him, but the two best items are the description of Chinese practice and the cogitations on the treatment of tough characters, on the third page. The book itself, which we again venture to recommend highly, contains many such humane and sagacious observations on those whom, as an engineer, the author employed in various countries.

FROM Denver comes an item of news that would be highly important if it were true. Mr. Elihu Palmer is reported by the Intermountain News Bureau to have predicted "the possibility that the American nation will enjoy soon sufficient wealth in gold and silver to pay the War debt, and much more", thanks to the "discovery, declared to have been made by chemists and metallurgists of this city recently that the oil-bearing shale-beds

are rich in precious metals". This is a yarn that has been repeated by irresponsible persons on various occasions during the last twelve months. Mr. Palmer explains that "revealing of these storehouses of wealth, which are surpassingly sensational in the prodigious quantity of gold, silver, and platinum the discoverers credit them with containing, appears to have been delayed until now only because the alchemists have not understood the combinations to the locks behind which King Midas has been hiding these treasures, likely throughout civilization". The last clause is cryptic and the remainder is flapdoodle unworthy of "release for publication" on any date. We are reminded of the celebrated brewery that was described as "a potentiality of wealth beyond the fondest dreams of avarice", but even a brewery in these days of prohibition seems to us a more likely source of money than these "oleagenous shales" as Professor (he must be a professor, to give the story local verisimilitude) Palmer calls them. "Confirmation of the entire discovery by numerous experts", it is asserted, was delayed until nature's secret was penetrated and the alchemists of Denver had ascertained the strange fact that "the shales must be relieved of their oil-creating hydro-carbons before they will respond favorably to ordinary assayers' practices." How many hydro-carbons were there and how does an ordinary assayer differ from an alchemist? Is the subsequent process of publicity and share-peddling likewise intended to "relieve" the simple-minded of their excess of something more tangible than hydro-carbons? Samples are said to have "given up gold, silver, and platinum only after having been completely decarbonized and oxidized while being subjected to a process designed to merely extract all the oil, gas, and ammonium sulphate". Next, presumably, will follow the even more fascinating process whereby the gullible will give up their gold and silver, and possibly their platinum-set jewelry, after having been completely bamboozled and spifflicated while being subjected to a method of spoofery designed to extract not merely their spare cash but their bonds and mortgages. To come to brass tacks, the oil-shale is said to yield \$15 per ton in three precious metals, although "many stratas" [weird things!] are "laden" with \$40 per ton, and only a few "as low as \$5 per ton". Moreover the additional cost, after distillation for oil, will be \$2.50 per ton for the recovery of gold, silver, and platinum. In the name of Shadrach, Meebach, and Abednego, or any other trio that underwent distillation by fire, how much money is there in the shale deposits of the West? Mr. Palmer tells us without hesitation; he quotes the U. S. Geological Survey estimate of sixty billion tons in Nevada, Wyoming, Utah, and Colorado, and on the modest basis of \$10 per ton, he finds their potential oil-value to be 600 billions "net". Then, adding the "precious-metal value", he finds a sum so large that he has to write it out, "one trillion five hundred billion dollars". What is the use of talking about aiding ordinary gold mining; here is a source transcending even the ocean, which, as everybody knows, contains gold in solution, or the moonbeams, which are made of silver.

Thus from shale is distilled a tale of the Arabian Nights and from the kerogen a yarn more smooth than vaseline.

MINERS of bituminous coal are now receiving 27% more for their work than was provided in the wage-scale in effect prior to November 1, 1919. This is the outcome of the award made by the President's Bituminous Coal Commission, that was ratified by the general scale committee of operators and miners in the central competitive field on March 31 and became effective the day following. The increase of 27% is substituted for the advance of 14% allowed by Fuel Commissioner Garfield when the strike was threatened last winter. The 14% increase added 104 million dollars to the cost of coal production; the new arrangement increases that amount to 200 million. According to the operators this will add from 65 cents to \$1.25 per ton to the cost of coal to the consumer; the representatives of the miners on the other hand contend that the additional wages will increase the cost of production by only 25 cents per ton and that the companies can and should absorb this by decreasing their profits. However, since the President is not inclined to make use of the power conferred on him by the Lever Act to continue the old, or establish a new, maximum price, and since there is an appreciable shortage of coal at the present time, prices will doubtless advance considerably above the Government standard of \$2.95, in effect prior to April 1. The contention of the miners that the working day be established at six instead of at eight hours, was denied by the Commission, on the seemingly tenable grounds that such a change would simply aggravate the present undesirable conditions and that it would be detrimental to the best interests of the mine workers, no less than of the public. In its report the commission concedes that any wage settlement is not an adequate solution to the coal-mining problem. The industry, as has been repeatedly pointed out, suffers from the fact that the quantity of coal burned during the winter months far exceeds that used in summer. Heretofore the policy has been to regulate production to synchronize with current consumption, and the result has been a seasonal variation in output that necessitated an unsound and inefficient organization of the whole industry. The difficulty is complicated by the problem of distribution as indicated by the fact that 49% of the time lost by miners was charged to 'car-shortage'. Stated simply, the solution is to mine and distribute a large part of the winter's supply during the summer. The three groups of consumers that require the greatest amount of coal are the railroads, the public-utility corporations, and the steel-plants. The first two classes operate largely under the regulation of various rate-making authorities and it is reasonable that added costs arising from the storage of a winter coal-supply be recognized in determining what service-rates may be allowed. By the proper application of this principle an adequate incentive might be offered to these corporations for obtaining surplus coal during the summer months. It is one thing to urge any group, by way of gratuitous public benefaction, to lay in its supply of

coal ahead of time so that the miner, the coal operator, and the rest of us would have smoother sailing; it is another thing to say to that same group, "If you will help out by spending the necessary money to put a supply of coal in storage and thus relieve a situation detrimental to all concerned the public will make good your expenditure." Here is a good place to make a start; the detailed procedure is not essential.

To Young Engineers

On another page we publish an abstract of an address delivered recently at the Michigan College of Mines by Mr. James MacNaughton, manager of the Cabnet & Hecla. This abstract is accompanied by sundry sympathetic remarks by Mr. P. B. McDonald, himself a graduate from the excellent mining school at which the address was given. Yes, mining is an art to which the sciences are applied; being based upon science, it is founded upon truth. Make-believe, in any guise, is its undoing. With Mr. MacNaughton's remarks on an apparently trivial matter, namely, personal appearance, we agree heartily. Men form impressions of one another first by appearances. It has ceased to be manly to be uncouth, either in clothes or manners. Time was when we in the West were on the frontier; we dressed like cowboys and talked a little like bad men from Kokomo; all that is out of date. There lingers an idea, among young men in our Western universities, that it is manly to be rough in speech and democratic to be slatternly in attire. At the University of California students in dirty corduroys fancy themselves suitably garbed for study in buildings of great architectural beauty and adornment. This is neither manly, nor democratic, nor American; it is simply provincial and ridiculous. It becomes neither a democrat nor an American to be boorish in speech, clothing, or manners. The American boy ought to be as well spoken, as decently dressed, and as gently mannered as any son of a duke but 15% more intelligent; that is the mark of a democrat, not a disregard for the amenities of civilized life. Next we turn to Mr. MacNaughton's reference to specialties. Undoubtedly concentration of effort is needed to promote proficiency in any one subject. The young American has the ability to devote himself enthusiastically to his professional work, and that is why, on the average, he becomes a competent engineer sooner than his contemporaries in other countries. We question, however, whether he is in need of urging that way; our own observation leads us to believe that he overdoes it already, becoming a specialist before he is educated and a technician before he is a scientific man. Even a good habit can be overdone. A broad training and a generous culture must be acquired when young, if at all; in them a man finds not only the development of capacity but a means of happiness. It is a mistake to specialize too soon. One can sacrifice much by being in a hurry to make certain of a bread-and-butter sufficiency. That is where a technical college, like the one at Houghton, may fail, as compared with a university like Harvard. Read Huxley's inaugural address at the opening of Johns

Hopkins University. The end of any college training should be moral worth and intellectual clearness, not the winning of a small salary immediately upon graduation. It is rarely indeed that a graduate just hall-marked with a degree is competent to give a full return for his pay. He is, as Mr. MacNaughton says, "a liability to his employer for awhile". He should remember that "for awhile" after he becomes worth more than his pay, as he soon will if he puts his head and his heart into the job. As to becoming surveyors and chemists, Mr. MacNaughton is right. These jobs are often mere *cul-de-sacs*; they may lead nowhere, unless they are combined with other work. A chemist in a smelter may get a chance to learn the technique of furnace operation and so become a metallurgist; a surveyor may consult daily with the mine superintendent until he acquires a knowledge of ore-finding; the thing to avoid is a comfortable subsidence into any mechanical task, such as surveying or assaying. Use them as doors or stepping-stones to something better; and that means a job involving the direction of other men's labors. Finally, be loyal. Be true to yourself, your traditions, and your ideals; then to those who befriend you and trust in you. Cheerful co-operation and intelligent loyalty are fine qualities; they are highly appreciated by those who employ young men; they are the qualities that in turn are essential to leadership among men. That is the aim and purpose of any special education: to produce men of originality and initiative, useful in their day and generation, and pioneers of human progress.

The Seattle Convention

The plan of holding an annual international mining convention in the North-West is now established, the second meeting, at Seattle, having proved a decisive success. Last year the mining fraternity along the border met at Vancouver; next year they will assemble at Portland. This convention is called 'international', but essentially it is Canadian-American, and, more precisely, it represents the mining activities of the States of Idaho, Washington, and Oregon, the Province of British Columbia, and the Territory of Alaska. It is true, the opening ceremonies at Seattle were graced by representatives of Chile and China; moreover, the slogan of that meeting was "the rim of the Pacific", and in furtherance of this idea we were told about the mineral resources, and the commercial exploitation of such resources, in the countries bordering the Pacific Ocean, but the dominant note of the meeting was goodwill and co-operation between the peoples on the two sides of the 49th parallel of latitude. A common purpose brought the English-speaking miners of a vast mineral region into harmonious deliberation and discussion. The convention was opened auspiciously by an admirably brief and appropriate speech by the chairman, Mr. Glenville A. Collins, to whom the success of the affair is largely due. The Mayor and the Governor were likewise crisp and to the point. The Bishop of Alaska talked the mining language like a 'sourdough' and Mr. E. T. Hodge responded for

British Columbia in felicitous phrase. As a geologist, he dwelt upon the fact that the continuity of the Cordilleran mining belt is unbroken from Chile to Alaska, the international boundary making no break either in the ore deposition or in the joint activities of the peoples along the border. The possibility of establishing an iron and steel industry on the Coast was the subject of the first regular session, the principal paper being read by Mr. Milnor Roberts, of the University of Washington. Three 50-ton open-hearth basic furnaces are in operation at West Seattle, besides a bushelling furnace of 1000 tons capacity per month and appropriate rolling-mill equipment. Magnetite and bog ore are said to be available in quantity, and coke is being made from local coal. An excellent summary of the coal resources of the North-West was given by Mr. Joseph Daniels, also of the State university. He brought out the fact that the countries on the opposite shores of the Pacific are vastly richer in coal than those on our own side, but he showed that the North-West has ample supplies of fuel, not to mention the water-power from which electric energy is obtainable for direct smelting.

Undoubtedly the overshadowing topic of the Convention was the restoration of gold to its normal status and the stimulation of its production at the mines. Occasional reference to the American discount on the Canadian dollar called forth a smile. It does seem unnecessary and ungenerous to show such financial inhospitality to the currency of our neighbors with whom we do a profitable business, more particularly as nine-tenths of the capital in British Columbian metal-mining enterprises is American, but it may be noted that the Canadian miner can, and does, obtain the benefit of the premium on his gold at the expense of his own fellow-citizens. Of the speeches made on the 'gold problem', two were especially noteworthy. Mr. Emmet D. Boyle, the Governor of Nevada, spoke for the miners. Formerly a miner himself and with recollections of experiences at Rossland, he was able easily to place himself in touch with his audience, which responded warmly to his sallies, especially his vigorous onslaught upon those most unpopular persons, the economists. He gave an account of the successive conferences called to consider the status of gold, beginning with the one that he himself called at Reno in August 1918, together with the reports of the various committees appointed to investigate the matter. The Armistice checked the efforts that had been set in motion to remedy the plight of the gold-mining industry, but the collapse of international exchange and the continued rise in the cost of living had revived interest in the subject, which was now expressed by a bill before Congress to impose an excise tax of \$10 per ounce on gold used in industry, that is, for jewelry, dentistry, and the like. The payment of a flat bonus the Governor recognized as unsound; it would strike at the foundations of credit and only make confusion worse confounded. The consumption of gold in industrial arts in the United States exceeded the production of our country in 1919 by 20 million dollars; the jewelers sold it at \$145 per ounce

when manufactured; therefore they could well afford to pay the \$10 tax, which would be given to the domestic producer of new gold. Other speakers, notably Mr. John Clausen and Mr. E. G. Crawford continued the discussion over two sessions. The enormous inflation of note-issues and other forms of paper currency was acknowledged, and the need for an orderly process of deflation was emphasized. The world was facing "the cold gray dawn of the morning after" its orgy of fighting and spending. At the last session Mr. Frank A. Vanderlip made an interesting appearance. He was on his way to the Orient and was to sail next day. His remarks came as a douche of cold water on the meeting, for he took a stand wholly unsympathetic with Governor Boyle and his mining friends. Mr. Vanderlip has the prestige of a national reputation and the experience of a trained publicist. He spoke well and with a frankness that did credit to his moral courage, for he was quite aware that his views were unpalatable to the audience. He sketched the evolution of paper money and the effects of the Federal Reserve banking system, emphasizing the enormous growth of the credit structure. There was nine billion dollars worth of gold in the world; the increase of output from the mines would bear no relation to an amount so large. There was three billions of gold in the United States, and we did not need any more; it would only serve as an excuse for further inflation of credit, for under the Federal Reserve system it would be legal to increase the purchasing medium at a ratio thirty times the amount of gold. We must cut down credits, he said, and increase the production of things other than gold. The miner was not the only man to suffer; the depositor in the savings banks and the holder of life insurance could only buy today two-fifths as much as his deposit or his premium purchased before the War. We must stop further credit expansion; we must learn to think nationally and internationally; we must get beyond making great decisions on personal relationships. The temperature of the hall had fallen until one recognized that it usually served as a skating-rink, but Mr. Vanderlip received a polite appreciation of his manly utterance, philistine as it seemed to the brothers of the pick and pan. They were soon warmed again by the Governor from Nevada, who proposed a resolution endorsing the legislation pending in Congress for the imposition of an excise tax on gold for the benefit of the miner. He demurred to the notion that gold was dedicated to the purpose of supporting credit; it was a commodity as well as a monetary standard; those who use gold for a commodity purpose ought to buy it on a commodity basis, not on the basis upon which it is required by the Government for money. The resolution was put to the meeting and carried without a dissenting voice. A number of other resolutions were passed, but we defer comment upon them until next week. In closing, we must not fail to acknowledge the generous tribute paid by Governor Boyle to the efforts made by the 'Mining and Scientific Press' to promote the investigation and discussion of the subject to which he himself has given so much earnest study.

Incidents in a Mining Engineer's Life

By E. T. MCCARTHY

[In our issue of January 31 we reviewed the second volume of 'Incidents in the Life of a Mining Engineer', a book written by Mr. McCarthy for the purpose of raising money in behalf of the St. Dunstan's Hostel for the Blind, near London. We referred to the unpretentious style and keen interest of his recital of experiences in many lands. Herewith we publish sundry excerpts, to which we have added some humorous sketches by our artist. The first excerpt describes life in Chiapas, Mexico, near the Guatemalan border.]

The one great amusement of the natives, outside gambling, was to collect on a moonlight night on our little plaza outside the store and dance. On moonless nights for a special treat I would sometimes give them a couple of pounds of candles; these they would stick about, and dance for hours like happy children. There were always a few who could play the guitar. The Mexicans are a musical people, and very fond of anything in the way of a guitar, violin, or banjo. The Guatemalans favored their national instrument, the marimba. This is an instrument played by three or five performers, who, with slender sticks ending in little india-rubber balls, beat its notes by striking on a series of graduated hard pieces of wood strung along two strings, much as on a glorified kind of child's glass piano, but here the glass-notes are replaced by wooden ones. Under each wooden strip, or note, is attached a gourd or inverted pyramidal pointed box, graduated in size so as to respond to the corresponding note above it, and near its apex a small hole is bored, over which is gummed a fine membrane. These boxes thus serve as a sounding board. Some of the larger marimbas have as many as 48 notes. The wooden strips run from about five inches to ten inches in length, one to two inches in width, and are about three-eighths of an inch thick, each strip very slightly concave on its upper surface. To get the exact tone out of them, the final adjustment is made by filing away their outer edges, a mere scraping being sufficient to tune them up when once the instrument has been regulated. The music from it is sweet and plaintive, being in the minor key. The Guatemalans also play on a wooden harp, crudely constructed and not unlike the Irish harp in shape. Our dances were orderly, and conducted decorously, which was a marvel to me knowing the elements that went to make them up.

• • • • •

While sitting on the verandah of my house one evening, soon after my arrival, as I turned to look down over the plantation, I saw innumerable bright little lights rising out of it and coming up slowly in my direction. What they could be I had no idea, unless they were the spirits of the dead. So uncanny was this miniature star-like floating firmament that I hastily ran out to call one of my

staff to ask him what it could mean. To my enquiry he said, "Oh, they are the fire-beetles." Fire-flies I have seen by thousands, but never any creature so brightly illuminating the air. Slowly they came up, and were wafted over us; I secured a couple of specimens, and put them under an inverted glass placed over a book. I could by their light distinctly see to read every word of the page on which they rested. This beetle is peculiar to the States of Chiapas, Campeche, and Yucatan. Immediately above its eyes are two little lights, about the size of a large pin's head, and with a light as bright in comparison for its size as any electric light, whilst under the thorax and extending for about a quarter of its length a light is emitted, similar to that of a fire-fly—that is,

HOW TO USE FIRE-FLIES

phosphorescent), but more intense, and covering a much larger area than in the case of the latter insect. The mystery was solved, and night after night for about three months these sort of lost souls used to come floating up over the hill. The Indians commonly use them as lanterns by placing a few in a small wicker basket, which they tie to the end of a stick, and hold over the trail to light their way by. The beetle itself has a long and narrow body, and is of a light-brown color, about three-quarters of an inch long and three-eighths of an inch wide. It seemed to use its wings only to rise with, and then, using them as a sail, floats along on any little current of air that may be about. Where they went to and what became of them I never was able to trace, nor did I ever see them returning, though perhaps they may have done so later in the night.

Another peculiarity about them was that immediately below the thorax there was a curious little bony projection forming a tiny bar; the women used to fasten a piece of cotton to this, and tie the other end of it to the head of a pin, which, sticking in their hair or dress, allowed the beetle to crawl about and decorate them with its soft light. I was told that in the season in Mexico City there was quite a demand for these beetles, which

were sent from Yucatan to the jewelers there, who gave about one shilling to two shillings a piece for them. These the jewelers would take, and, substituting the cotton and pin with a very fine gold chain and hold pin, sell to the ladies for the same purpose. I have never come across any description of these beetles in any magazine, and the references made to them in natural history encyclopedias give little idea of how bright those little lights are, especially the ones over the eyes, forming, as it were, a kind of port and starboard light. I have kept several alive for weeks by feeding them on sugar-cane, and made many attempts to send live specimens home through the post, either in match-boxes, or in a hollow piece of sugar-cane, but, although the boxes and cane arrived home, they were always empty, the postal authorities having doubtless discovered the presence of the beetles by the little gnawing noise they make. I have myself often used one of those wicker-work cages to show me the trail.

At a little distance from my hut I had a favorite bathing pool just beneath a little waterfall. In it was another of Nature's curiosities, little fish about two-thirds the size of a common sprat. These used to come to the surface, and shoot out from their mouths little globules of water at small flies or mosquitoes, and unerringly knock them down from a distance of about two or three inches; these they quickly swallowed. I have watched them by the hour and seldom scored a miss against them; to me they were always most fascinating.

Another of Nature's wonders was a species of bat, but not of an interesting kind, for they were the plague of my life. At our mule station at the mine and the one beyond, these creatures used to attack our mules at night. The method of attack is to flutter their wings gently over the mule's neck while they suck its blood from the jugular vein. In the morning the only sign of their having done so is a small dry stain of blood, hardly noticeable unless looked for. Night after night they would so attack the mules, with the effect that gradually they lost weight and got thin. At first we used to change the mules frequently with those at the lower stations, and so give the poor creatures a chance to pick up. From one of the directors of the Tolima mine, in Colombia, where they had similar trouble, I got a good tip which, when put into force, proved effective. The remedy was to enclose the stables (on account of the heat they had to be open ones) with old screening used on the mill, and to hang up thorn brushwood above the mule's backs as they stood in their stalls. If by chance then any bats succeeded in getting into the stable they got entangled in the brushwood. Thus in a simple manner we got over a plague that had proved quite a serious matter.

* * * * *

During my sojourn here, as we had no medical man we had to be our own doctors and surgeons. The assistant-manager was more of the latter than I was; I hated the work. In stab-wounds and sewing up cuts we were both pretty good. The Chemula Indians, who cut fire-wood and roughly squared logs, also timber for the mine, were always cutting themselves about the legs, and they

gave us the most trouble, for their skins were so thick and tough—more like pig's skins—that we failed to get a needle to pierce them until we hit on a dodge which

SURGERY FOR NATIVES

acted admirably; this was to take a fine bradawl and bore the holes with a piece of cork placed beneath the skin, and then to pass the needle with the gut through them. I used to abominate this job, but it had to be done. They were either stoical or had no feeling, for they never flinched an inch under the operation.

These same Indians were fairly numerous in our district, physically a sturdy, broad-shouldered, well set-up people. No one could induce them to enter the mine; during the time of my management only one ever did so. They were truly hewers of wood and drawers of water. They spoke a language that, to my ear, was unpronounceable with its multiplicity of consonants clustered together, apparently with the minimum number of vowels that could be used to produce a sound. In features they were not at all unlike the Northern Chinese, and as brown as berries. They still refuse to pay taxes to the Mexican government, and they allowed no foreigner to enter their villages. I frequently asked some of the oldest of our workpeople if they would receive me in their village, but they always said they had to do as their Cacique instructed them, and therefore could not. The loads they carry were actually equal to those we put upon our pack-mules, or 240-lb. weight per man in the hilly country, and these were not merely carried short distances, but over long ones, 15 to 25 miles being about a day's journey, varying according to the steepness of the hills. These loads they perched on a wooden frame-work strapped to their backs.

* * * * *

Our head blacksmith was a well-known desperado, who more or less terrorized the camp; a good blacksmith himself but no good in controlling others under him. I had sent for an English blacksmith, but had told the former that, while his pay would not be reduced, he would be under the new man when he arrived. As I was dressing one morning, and had just finished putting on my coat, a knock came to my door, and the blacksmith walked in

without permission. I noticed he had his *poncho* on; it was a hot day, and unusual to see him in it. I had a big table in the room, and divining he might be up to some mischief I kept it between him and myself, walking slowly round it as he came round. He was arguing about his position. I told him to clear out and go down to the office, where I would be in ten minutes, when I would discuss the matter with him. He went out as told, and a few minutes afterward I left my room and was walking down to the office when I saw my second blacksmith staggering up the hill toward me, then falling down. We picked him up, and carried him into a house near-by, where he died ten minutes later. There was no sign of blood about him, but on stripping him there in the groin was a stab. Then it came out that the head blacksmith had gone up to him, held out his right hand to shake hands, and called him "*amigo*"—that is, friend—and as they clasped hands, he, with his left one, drove his knife into him. I sent for our chief policeman and ordered him to arrest the culprit, but he assured me that there was not a man in camp who dared to, and besides, if anyone dared, the camp would liberate him. So I walked down to where the man had gone, and told him to give me his knife. That knife in the first place had, I felt sure, been meant for me, and had been hidden under his *poncho*. I felt quite confident he would obey me, and had no fear of him. He did as he was told, and personally I locked him up in the jail. The same day I sent him to the police authorities, but in two months he was out of prison, and wrote asking me to reinstate him. His friends had collected about £20, and had bought him off.

The authorities came up after the murder, and demanded a *post mortem* on the victim. We had no doctor within 100 miles or so, but I bluffed them. I had my Red Cross certificate, signed by Earl Granville; this I produced, and expatiated on his name and signature, and pointed out the Red Cross on it, so that they were persuaded I must be a qualified surgeon. Forthwith we exhumed the body, and before them, by the light of two candles, we, the assistant-manager and myself, dissected the wound, a mere formality. The absence of blood was unheard of, and I think curiosity had something to do with their demand. I said it was now clearly proved that he had bled internally, and that was the cause of the death. With this they were satisfied, and afterward they sat down to supper with me, but I had no appetite, for the whole business had been so ghastly, carried out too by the dim light of tallow candles, and on a body that had been buried several days. I managed, however, to keep my wrath to myself, but I hated the sight of these individuals, who came and gloated over the *post mortem*.

* * * * *

Only one mishap happened, about a fortnight later: as I was coming up from below the mill I suddenly saw a great volume of smoke, as I thought at first, but what happened was that my pipe-line had burst, and a solid column of water was being shot up some 200 ft. or more high into the air, and was falling back in great clouds of spray. The cause of this was that near the mill I had

inserted a tee piece, with the intention of taking a branch pipe-line off it at some future date, and over the open end of the tee I had bolted a half-inch plate of cast-iron. Thinking this amply strong enough to resist the pressure, I had never calculated its strength, and it was this that had burst; but beyond a temporary shut-down no harm was done, and a new and stronger cover was soon in its place. Later in the season we had two or three days' torrential rains, and at 8 p.m. one night the mill shut-down; no water was coming down the pipe. It looked like a block at the inlet. It was raining in torrents, a pitch-dark night, and no easy job to go up the trail.

I called for volunteers from some of the night-shift men, and they were quickly forthcoming, the mine captain and myself going with them. Slowly we made our way up the hill, until we came to where the pipe-line crossed a chasm with a 22½-ft. span. The question was should we take the wide detour around it, or straddle across it? We decided on the latter. When half-way across a Mexican behind me asked if he should take my lamp, which was encumbering me in my efforts to straddle on. I recognized his voice. It was the very man whom I had always kept my eye on as the one man I was doubtful about. A push from his little finger would have unbalanced me and sent me to my death! I need not say I afterward took care to see he was helped to a better berth than the one he then had.

On arriving at the inlet it was found the pipe was blocked with branches, dead wood, and leaves. After a hard task we succeeded in clearing it, but on my return I could not quite divest myself of my suspicions of this man, and took care he was not immediately behind me again. We all got back chilled to the bone with the cold rain, and had to run a considerable risk both on the trail and in clearing away the debris, and I could only wonder what made those Mexicans volunteer to accompany us, for no extra pay had been promised them, and they asked for nothing extra. After arranging for others to take their places that night, we let them go home.

The more one sees of humanity, however debased, however bad, there is always at the bottom a good side, no matter whether barbarian, semi-civilized, or civilized; the difficulty is to get at it. The worst criminal respects the man over him who seeks to be just, and who, though outwardly hard, yet has his welfare at heart, which he knows instinctively, for it is not by talk or argument he is convinced; perhaps it is by an unconscious kind of hypnotism that passes between the two parties, or it may be that each finds some good or something to be respected in the other. So many times in my life have I momentarily been in the hands of what we could call villains, yet I have had no fear, nor even nervousness about safety. Neither was it by any egoism that I could command them, but by an inexpressible consciousness that they would respond to my demands.

* * * * *

[The following incidents relate to life in South Africa.]

I had made arrangements to take my wife and son

back to the mine, but before doing so I went up the line to visit another mine beyond the Sheba. Arriving at the nearest station to it, a Kafir met me with a horse to ride out to the mine. It was a boiling hot day, and I had some seven to eight miles to go; the sun was glaring down on me with more than ordinarily piercing rays—at least, so I thought—and I was anxious to push on, but my beast would not. What sort of an animal it was I could not determine; it might have been a sheep in a horse's skin (for beyond a sheep's sort of gait I could not get it to go), and those seven or eight miles took me three hours to make. Meeting the manager, who was walking on crutches, I warmly asked him if my horse was purposely bought for his special benefit, as I could imagine it was only fit for a cripple.

Here I stayed to inspect the mine, located at the top of some hills overlooking the valley in the camp below. The ore from it was brought down to the mill by means of an aerial ropeway, along which the buckets traveled to and fro, but no one was permitted to travel in them; the law prohibited passenger traffic. Now, as it was a long way round to the mine, and uphill the whole way, I said I would 'inspect' the ropeway, and go up in a bucket—this would not break the law. From the receiving station at the mill I started, seated in the bottom of one of the numerous buckets which hung at regular intervals along the rope. All went well until about half-way up, when the ropeway stopped, and there I was left suspended between earth and heaven with a clean drop of about 200 ft. What had happened? They shouted up to me, but I could hear nothing that was said. In that iron bucket, with the sun's full glare on it, it was like being slowly

ANOTHER PERIL OF MINING ENGINEERING

almost the moment after starting the brute threw up its head, seized the bit firmly in his teeth, and made a clean bolt of it. I whizzed past the mill, and along the straight road leading to the station, when it took me all my effort to keep my seat. Suddenly my mount swerved off the road, making direct for the timber not far off. There was nothing left to do but to come off, for if I entered the timber it would be almost certain death. Hitherto I had been gripping my saddle tightly; relaxing my hold I did not come off, though I wanted to, and it was only by a great effort I east myself off the brute, when I pitched on my head and saw the moon and stars. Rising in a dazed state, I found blood trickling into my eyes, and my right hand was disabled. There was no water near-by, so I retraced my steps back to the road; here I had the luck to meet a Kafir boy leading a riding-horse going in the direction of the station. My bloody appearance frightened the little chap, and I had no difficulty in getting the horse, for the boy cleared off. The job was to mount; with considerable difficulty I did so, and rode the remaining two miles.

That evening the doctor came in, and made me plank my hand down on the table while he, with a pair of forceps and lance, picked out the dirt and cleansed out the wound. This took two hours to do, and during them I suffered excruciating torment, but he made a good job of it, though it was quite a long time before I got the use of my hand again. I had to keep it in a sling high up, for if I lowered my arm the pain was severe, otherwise I felt little of it. I learned afterward that the manager had broken his leg by that same horse having bolted with him, and it had not been ridden since until I mounted him, so my friend paid me out for my growling over the first horse he had sent to me. I also learnt that I had unwittingly caused the death of a Kafir boy who, as I rode past the aerial ropeway, happened to be pushing off a bucket onto the rope. Seeing me, he hung too long on to it, and was carried off his perch and left suspended in the air. Unfortunately he had not the pres-

IN A BAD FIX

cooked to death in an oven. After an hour and a half thus suspended, the bucket again began to move, and in a few minutes more I was safely landed at the mine. What had happened was that the landing-man had surreptitiously gone off, having taken a holiday, and left a friend of his to take his place. This man, seeing a passenger coming up in the bucket, lost his nerve, and stopped the tramway. He then went off to find the man whose place he had taken, and I had to wait until he turned up.

ence of mind to climb into the bucket, but hung on until, letting go, he fell from a great height, and was instantly dashed to a pulp.

* * * * *

[Next we go to China.]

Taking a walk a little way up the latter river we witnessed for the first time the Chinese fishing with their cormorants. Seated on a raft anchored out in the river were one or two Chinamen, with a few brown earthenware jars, used as reservoirs in which to place the fish. Sitting beside them were the birds themselves, who, evidently at some signal from their masters, would dive into the river. The water was so clear that they were easily discernible below its surface and could be seen diving at incredible speed. Seizing a good-sized fish in its bill, up one would come and leisurely swim to the raft, where

REAL SPORT

the fisherman would take the fish out of its mouth and throw it into one of the big receptacles. Then he would dip his hand into another and pull out a small-sized fish, giving it to the bird, which would immediately swallow it. As many as six or eight cormorants were attached to each raft. Fastened round the bird's neck was a loose metal ring, which, we were told, was to prevent him from swallowing the bigger fish.

* * * * *

I had an experience at the mine which I should not like to have repeated. Down the main shaft was the ladder-way to the bottom of the mine, 300 ft. below, but instead of a series of inclined ladders there was one continuous ladder the whole way down. The inside of the shaft-timbering was lined with two-inch boards, and there was not a chink into which one could put a toe. Down this ladder I descended, but long before I got to the bottom I was tired out. Think what it was to come up! A 100-ft. vertical ladder is always a stiff climb at any time, but I had no idea of what 300 ft. meant; the heat, too, was tremendous. The first 200 ft. I surmounted comparatively well, but the last 50 ft. I shall never forget. As I got nearer and nearer the top of the shaft my strength was giving out; that last 25 ft. nearly bested me; I tried to get rid of the weight of my body by all manner of expedients; I stuck my arms right through the rungs up to the arm-pits endeavoring to get

a rest, I tried to put my knees between the rungs, but to no purpose. Another 20 ft. to climb! As I stepped off the ladder I found that all the strength had so completely gone out of my knees that I sank right down and for some minutes it was impossible for me to stand upright. Let any miner used to climbing a 100-ft. ladder try a 300-ft. one, and he will find that it is a perilously dangerous feat to accomplish. The Chinese, though, made no difficulty about it. Until I had attempted it, I had not the remotest idea of the severity of the task. Another time, by making a Chinaman take a light scantling, and by putting one end through a rung of the ladder and the other leaning against the opposite side of the shaft, I got a kind of light staging to rest on.

This shaft had been sunk and timbered as a winding-shaft; but here comes in the absurdity of the whole business: after all the cost of it and the cost, too, of boilers and engines brought all the way from America, it was decided that if erected it would bring bad luck; it was a *fenshui* business. Instead, they continued their old methods of hoisting the ore by a forest of little windlasses placed across the timbering, which reached from the surface to the bottom of the mine in the open space left along the line of the lode by the extraction of ore in the past. Each little windlass drew up from a depth of only about fifty feet, and so on all the way down. Each, again, only drew up a tiny basket of ore at a time. The lode carried a most wonderful variety of gold, silver, lead, zinc, copper, and arsenic ores. All this ore when brought to the surface by the above primitive methods was placed in large, open, paved yards where it was broken up by hand and then carefully sorted out into its different grades. From these ore-heaps it was carried in baskets by hand to the smelting establishment where, under huge red-tiled sheds, were the furnaces for smelting the lead ore, and near-by were the mills in which the gold ore was being treated. There were other mills, too, where the silver and copper ores were being treated by wet methods.

In the smelting-works Chinese methods were to be seen; a crude mixture of the East and West prevented the use of the modern reverberatory furnace in smelting the lead ore. Two modern furnaces had been built at great expense, but the man in charge knew nothing about their practical working. The very essence of the working of these furnaces is to admit air, but he had systematically shut it all off; so the galena ore was merely melted down, and no lead, as should have been the case, was produced. The reverberatory furnaces, therefore, were quite useless and unnecessary, only an additional expense.

The argentiferous lead was being refined in a German cupellation furnace, and the silver thus obtained from the lead was quite satisfactory, but this lead was smelted in a large number of rude little open-hearth furnaces and not in the reverberatories. Again, the cupriferous silver-ore, other than the argentiferous galena, was being washed with salt and treated with good results by the Russell lixiviation process, which is a most difficult process and needs a high chemical knowledge to work it;

in it the copper is finally precipitated by means of scrap-iron. But the simplest extraction, namely, that of the lead ore (the bulk of the output) in a modern furnace was a dead failure.

The whole business was a conundrum, for how was it possible for them to conduct complex processes successfully and yet fail on the more simple one? The answer I found to be in the Chinese system of control. The manager of such works must be an accountant, and consequently has no technical knowledge. The superintendent of each department is chosen by him, and if anyone is a failure he had to find it out himself; for if any superintendent was to complain of the incompetency of another one, while the latter might lose his job the former would certainly do so for going against Chinese custom. Here was a case where the head chemist knew perfectly well the reason of the failure of the reverberatory smelting, but he dared not say or he would have lost his job.

[From China we proceed to the Malay States.]

A few miles from the main camp was the logging-camp where the timber used in the mine and for construction of the mill was cut down. Some of the elephants employed in bringing in the logs to the saw-mill were brought up to the mine-camp during my visit, and every evening these used to go into a pond before sunset for their bath, and I always endeavored to get home in time to watch them. Like so many children they used to play and sport about in the water and spout water over each other. Their *mahouts* would first scrub them down with regular scrubbing-brushes, making these huge brutes lie down on their sides while they operated upon them.

On the Government post-road, two of these creatures were used to carry the mails. The smaller one was always given 20 minutes' start before the larger one was allowed to proceed. The little one usually came tearing in ahead of the other, but sometimes the bigger one would catch up with him and then give him a regular lambasting with his trunk. Another time I was coming across some paddy-fields on top of their mud-built banks, when I perceived one of these creatures coming toward me carrying on its back a whole family of Malays with all their household goods hanging down its sides and tied by bits of rope and string. Was I to go back or was the elephant? There was no room for both of us to pass, so I waited to see what was going to happen. When the elephant had nearly come up to me the *mahout* stopped it; then I saw it with one of its forefeet making a foothold with its hind foot, on which it rested, leaving me enough room to pass. I don't know at which I was the more astonished, at the intelligence of the animal in thus making way for me, or at those frail mud walls standing the weight of the great beast resting at an angle on their sides. Strangely, this was the second time I had been caught when crossing a paddy-field by an elephant, with just such a family on a removal. There is no other animal with such intelligence, and it is astonishing how they will help each other when at work.

An amusing incident at the logging-camp occurred

during my stay here. The superintendent was the only white man living there, and he lived in a comfortable bungalow with a nice staircase or pair of wooden steps leading up to his front verandah. Twice a troop of wild

SPORTIVE ELEPHANTS

elephants came down and carried off this stairway, completely destroying it. Soon afterward, when the Chinese coolies were all at work in the middle of the day, the elephants entered their lines and deliberately pulled down every house within them; but not a woman or child did they touch, though naturally both women and children were very much frightened. Nothing but pure wanton mischief! The Government officials decided to build a big stockade and entrap this troop into it. The drive was to take place a fortnight after I left the mine and I regretted very much that time did not permit me to stay and witness it. The description of how the tame elephants are used to effect this capture of the wild ones is marvelous, again proving the wonderful sagacity of these creatures. Elephants that are caught and broken in this way mostly pine and fret to death, so that the authorities seldom resort to capturing them, and only do so when they become a nuisance or a danger.

STATISTICS on the mineral production of Quebec show that in chromite, the decrease both in quantity and value has been very marked. The figures for the year 1919 are 8184 tons shipped, valued at \$223,321, as compared with 23,000 tons valued at \$770,955, a decrease of 64% in quantity and 71% in value. Nevertheless the present production is equal, in quantity, to the shipments of chromite from the mines when the industry was at its zenith under normal conditions in pre-war times. Considerable development work was effected during the year 1919. Two new concentrating mills were built, and there is every appearance that the industry has taken on a new lease of life.

THE test of concrete tanks made of 1:2:4 mixture and used for water storage, undertaken by the U. S. Bureau of Standards, has been discontinued after 150 days because the day-loss curves have taken the form of a straight line, showing that the daily loss has become constant. It may be of interest to note that these tanks, although showing some actual loss, due to water penetrating the concrete, remained dust dry on the exterior. It would seem from this that although the head of water amounted to 35 ft., the 1:2:4 concrete is sufficiently waterproof for this purpose.

Mine and Flotation-Plant of the American Graphite Company, Near Ticonderoga, New York

By C. E. CHAFFIN

INTRODUCTION. The mine and mill of the American Graphite Co. are situated at Graphite, Warren county, New York, about 12 miles south-west of Ticonderoga, which is the railroad shipping point. Graphite was first discovered in this vicinity in the early 'forties. About ten years later the American Graphite Co. was organized to develop and operate the deposits at Lead Hill, three miles from Ticonderoga; and men and machinery were brought from England to start the first graphite mine in the United States. The Joseph Dixon Crucible Co. later

cleavages. Granular graphite is also found associated with the above. This mine has not been much worked, but a considerable quantity of pure graphite is annually obtained from it, which is sold for a shilling a pound. It is thought that this is an extensive deposit."

At Graphite there are two distinct parallel beds of schist in which the graphite occurs, both dipping from 10° to 40° to the south-east. The lower bed, which alone is now being worked, consists mainly of a quartz-schist which varies from a few feet in thickness to about 30 ft.;

THE MILL

acquired control of the property and thereby centralized in a single organization the direction of all activities from mine to factory in the production of high-grade materials. After 20 years, when the operations at Lead Hill became unprofitable, the present property at Graphite was opened and has produced continuously since. There are some 25 other graphite properties in northern New York. Most of them have been operated for a time, but, so far as known, the operations have not been generally profitable and at present most of the plants are idle.

GEOLOGY. Beck* describes the Lead Hill deposit as follows: "It is a vein of the purest foliated graphite several inches wide. The foliae often have a radiated arrangement and are of considerable size. The gangue is calcareous spar, which often exhibits large and perfect

possibly 20 ft. would be a fair average. The lower bed averages 6% graphitic carbon; the flake is exceedingly thin and tough, and commands a premium price for use as a lubricant. The flake in the upper bed is small and brittle and at the present time it is not profitable to exploit it on account of the high proportion of dust produced. The upper deposit has an average thickness of approximately 12 ft. and is separated from the lower by from 20 to 40 ft. of garnet gneiss. The foot-wall of the lower bed is garnet gneiss, while the upper is capped in some places with limestone and in other places with gneiss. Above the capping the quartzite extends to the surface.

In the western part of the mine the formation is faulted and the main orebody was lost. In 1914 it was realized that the portion of the mine then developed was prac-

*'Natural History of New York', 1842, pp. 96-97.

reality worked out. When the War stopped importation of foreign graphite, the Dixon company found it necessary to increase production from its own property. T. B. Holmes, the present mine manager, after making a comprehensive study of the fault system, evolved some new ideas as to the faulting in this part of the mine, which were corroborated by diamond-drilling. It was found that the main or lower bed had been thrown almost vertically upward for a distance of approximately 100 ft. Additional drilling in this section has proved sufficient ore to maintain output at the present rate for 12 years.

MINING. Mining operations are carried on through a main haulage-tunnel that extends into the hill in a south-westerly direction for three-quarters of a mile. The maximum depth below surface is about 300 ft. Owing to the slight dip of the beds, the mine is worked in a manner similar to the room and pillar system in 'pitching seam' coal mines; the roof stands well and very little timber is required. Operations have been extended following the dip to the south-east for about $\frac{1}{2}$ mile. Since the present mining is all done below the main tunnel-level, small electric hoists are used to handle the cars on the steep grades. Electric locomotives are employed in the main haulage-tunnel and modern air-drills are used throughout.

The 'summer' open pit is east of the mine proper and has been operated only in the summer on account of the water. Recently a diamond-drill hole tapped the water, and the pit now may be operated until cold weather prevents. It is likely that the orebody exposed in the pit is an extension of the lower bed.

MILLING. The main mill building was erected more than 60 years ago, and during that time the foundation posts, below the ground level, have been renewed three times. The first machinery was designed in England and a large part of it was made there, but American-built machinery gradually replaced the foreign equipment. For a long time stamp-mills and buddles were used. In 1918 the General Engineering Co. of Salt Lake City was retained to re-fit the plant with modern concentrating machinery. The present mill started in the latter part of 1918 and has given satisfactory results for over a year. Because of the radical difference between the old machinery and the new, doubt was expressed by some as to the success of the plant, but this skepticism is rapidly disappearing in the light of the results actually obtained.

The main haulage-tracks emerge from the hill just above the mill-site and pass over a short trestle to the crude-ore bin. A No. 6 McCully gyratory crusher is placed under this bin and the ore is fed to it by hand. The product is carried on an 18-in. inclined conveyor-belt to a bucket-elevator, which in turn delivers the material to a trommel having one-inch round openings. The undersize goes direct to the fine-ore bin; the oversize passes through a set of rolls and thence to the same bin. The dry-crushing plant appears to be rather complex, but it was re-built so as to alter the scheme of the old plant as little as possible.

The ore next is fed to the ball-mill by means of a 16-in.

combined feeder and conveyor. The first grinding, to 28-mesh, is done in a 6 ft. by 22-in. Hardinge ball-mill operated in closed circuit with a standard duplex Dorr classifier. A heavy circulating load is carried in order to separate the graphite in as coarse condition as possible. The flotation-oils, fed to the ball-mill, increase the surface-tension of the pool in the classifier, thus allowing the coarse flakes to overflow the classifier, if they reach the surface, even though they may be coarser than 28-mesh. Lately it has been found advantageous to send the ball-mill product to two Deister cone-baffle classifiers and treat the spigot products of these in the Dorr. The overflow products from both classifiers combine to supply the flotation plant.

The flotation machines are standard Callow pneumatic cells arranged somewhat differently from ordinary practice. Four cells are used as roughers and make a final tailing, and a concentrate that is sent to two primary cleaner-cells. The primary tailing is returned to the rougher-cells by means of a bucket-elevator, while the concentrate at this point is screened on 100-mesh. The oversize goes to a 5 ft. by 22-in. Hardinge pebble-mill and the undersize, combining with the pebble-mill discharge, is re-floated in the first and second re-cleaner cells. The concentrate from the second re-cleaner is screened on 100-mesh; the oversize goes to a second Hardinge mill, and the undersize, combining with the pebble-mill discharge, is re-floated in the third and fourth re-cleaners. All the cleaner tailings are returned to the flotation-circuit. The final concentrate is obtained from the fourth re-cleaner and is run into settling-tanks where it drains for eight hours. These tanks have one side made of canvas in order to help the draining. From the tanks the concentrate, containing about 40% moisture, is shoveled by hand into a screw-conveyor that discharges into a revolving dryer, from which it is elevated into a storage bin. The finer sizes of concentrate as well as the purer flakes of graphite, which would otherwise go up the stack, are recovered in dust-collectors. Three grades of product result.

The sides of all the cleaners are raised about 12 in. and three wooden baffles are placed across the cells at equal intervals. The baffle nearest the discharge is level with the top of the original side; the next baffle is about three inches higher, and the third three inches higher than the second. This divides the cell into four compartments and the concentrate, in flowing from one compartment to the next, forms a small cascade over each baffle. The concentrate is taken from the end of the cells instead of from the sides, so that in the froth zone it must travel the full length of the cell (8 or 9 ft.) before being discharged. This arrangement of baffles is effective in producing a high-grade concentrate.

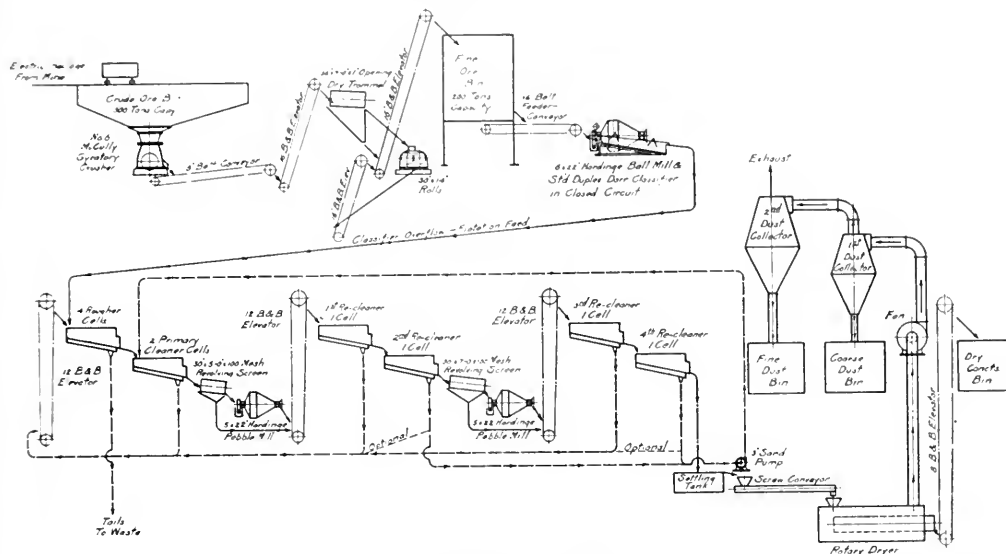

Several features somewhat out of the ordinary are found in the plant. Graphite, being a lubricant, caused some difficulty in the crushing and grinding operations; high-grade pieces of ore were particularly troublesome. Accordingly the head and concaves of the crusher are made with slight longitudinal corrugations that serve to

force the lumps of ore downward as the shaft turns. Although the feed to the 30 by 14-in. rolls had passed a one-inch screen it was found that the rolls would not nip occasional pieces of high-grade ore. Accordingly in the outside of each shell, eight sets of four 1½ in. diam. holes were drilled almost through the metal. This overcame the difficulty effectively. Similar difficulty in the ball-mill was overcome by increasing the speed of the mill. The 100-mesh revolving screens were made at the plant out of silk instead of metal cloth. Silk lasts much longer than wire in this particular service.

The mill operates 24 hours per day, six days per week, and the average actual tonnage is slightly more than 100 tons per day. The mill-heads average 51% graphitic carbon and the total concentrate by months averages

few minutes, while the lower grade concentrate from the dryer requires a longer period. After being ground, the material is screened in gyrating sifters similar to those used in flour mills, the coarser sizes being higher-grade. From the refinery the graphite is shipped in barrels to the Joseph Dixon crucible-plant in Jersey City, where it is used in the manufacture of a variety of products.

ONTARIO produced sundry precious metals during 1919. Platinum and palladium were recovered at Port Colborne, and also by the International Nickel Co. at its Bayonne refinery. At the latter 19,528 tons of bessemer matte was treated during the year, from which platinum, palladium, rhodium, osmium, iridium, and ruthenium was recovered. In all 1770 oz. was obtained, the

FLOW-SHEET OF THE MILL

86½%, while the coarse concentrate averages 91%. The present output of the mill is about 350,000 lb. of concentrate per month. The average actual recovery for 1919 was slightly more than 87%.

The mill and the compressors are driven by steam. A direct-current generator supplies power for the electric locomotives and for lights. Anthracite coal is used in the boiler-plant.

The dried concentrate is bagged at the concentrator and hauled to the refinery at Ticonderoga by team and truck. The three grades are kept separate, as the higher grades require less grinding. The refinery process consists simply in further grinding and screening. The grinding is done dry in cylindrical mills using small steel balls. A charge of concentrate is run into one of these mills and ground just long enough to free the graphite flakes from any small particles which may adhere to them. The concentrate from the dust-collectors at the concentrator is higher-grade and is ground for only a

estimated value being \$200,000. No definite figures are available for matte treated by the Mond Nickel Co., consequently platinum metal recovered from Coniston matte is not included. Quotations on the rarer metals are difficult to obtain. The average price of platinum for the year was \$114.61 per ounce. Palladium has been valued at \$130. Iridium is now quoted nominally at \$300 per ounce. The average value of iridium, imported into the United States in 1918, was \$114.18 and for osmium it was \$58.40 per ounce in 1918.

PLATINUM is derived from two main sources—lode deposits and placers. In the latter type the metal occurs native in the form of grains, points, pellets, and nuggets associated with gold, iridosmine, chromite, garnet, and other minerals. Lode deposits contain platinum usually in the form of sperrylite, the arsenide of platinum, although in several ores of this type the mineralogical form of the metal has not yet been determined.

Mr. MacNaughton's Advice to Students

By P. B. McDONALD

James MacNaughton, vice-president and general manager of the Calumet & Hecla Mining Co., recently delivered an address before the students of the Michigan College of Mines. Although the speaker explained that he had never given a lecture before, one could not fail to be impressed by such a speech coming from such a speaker. In order that a wider circulation be given to Mr. MacNaughton's advice to students of mining engineering, I have made the following summary of his arguments:

"There is no more upstanding, dignified, honorable, or independent profession than mining engineering. In engineering generally, you cannot evade any responsibility and you cannot blame your mistakes on anybody else. The profession is founded on the exact sciences. You have got to stand or fall, as engineers, by your individual efforts.

"The young fellow starting out in life has an idea that in order to make a competent and really first-class, high-toned engineer, he has got to start out by buying a pair of long-legged boots, and then he has got to go further and get his trouser-legs into these boots; and then he has got to get a flannel shirt and turn his collar up just as high as he can. If you appear before a prospective employer with a two or three days' growth of beard on your face and those same high-topped boots on, you are not apt to go very far; he is apt to rank you with his chauffeur; he may have a great dislike for high-topped boots, he may like low shoes; you never can tell. Beware of the high-topped boots, boys, unless you have to use them. It is not necessary to wear high-topped boots to go to the post-office."

Mr. MacNaughton then explained that a capable man recently was being considered for a position with the Calumet & Hecla, until he appeared in person. The man had half a bushel of hair on his head! "I didn't hire him. I didn't like a man with so much hair on his head; it would annoy me. I should always have been nervous with that crop of hair near."

Next Mr. MacNaughton advised the young men to get wrapped up in their respective specialties. He cited a manufacturer at Kenosha, Wisconsin (who undoubtedly buys brass made of Michigan copper), who has made a great success of making and selling beds. "That man thought in beds, he slept in beds, and he dreamed in beds. That is what has made his business a success. He was 'bugs' on beds. His ambition is to manufacture 10,000,000 beds a year; he is going to do it and he will do it. That man made a success of the bed business because he lived in beds. With him beds were the whole thing. Mr. Simmons didn't need to make beds, to make a success; he was that kind of a man, he was on his toes, he knew what he was doing."

Such illuminating little touches as this one about beds help us to interpret one successful man's opinion of

another successful man. In brief, the explanation of success is to concentrate entirely on one's specialty. If you manufacture carpet-tacks, live only for carpet-tacks; if you mine vanadium, think only of vanadium; if you catch fish for a living, dream only of fish.

A student just before graduation, said Mr. MacNaughton, imagines that "the world is standing absolutely stock still and just waiting for you; in fact, for the last three months before graduation, very little has happened in the world, it has just been waiting for you individually to get out and give it the extra push to get it going again. Every college graduate has felt the same way, myself among the number. But you will become disillusioned soon enough; the world is not waiting for you; it is going around all the time. You must realize, if you get a job, that you will be a big liability to your employer for awhile; some of you will be a liability for a longer time than others, and I have known in my experience some college graduates who were always liabilities; they never got over it; they like being a liability. Nobody wants to hire a liability, but they have to."

Mr. MacNaughton deprecated the engineering graduate's beginning life as a surveyor or chemist. Said he, "I don't think much of that, I think you ought to start in as trammers; we are short of trammers and we can give you all jobs. You can't learn too much about it; you can't begin in too humble a position."

One of the most impressive of Mr. MacNaughton's bits of advice was that about understanding men. "You need to look at the situation from the other fellow's standpoint, but bear in mind that unless you do acquire that characteristic, unless you do know men, you will not be able to handle them successfully. Cultivate that. By that I don't mean patronize them. There is an old saying, 'If you mix with the swill, the swine will eat you.'"

Mr. MacNaughton concluded his address by advocating loyalty. "Don't knock him [your employer] behind his back; speak well of him. Advance his interests wherever you can; boost for him; yell for him. I cannot speak plainly enough as to the loathing with which an employer looks upon a disloyal employee. Christ said, 'No man can serve two masters.'"

The students were deeply touched by the address, and felt fortunate in hearing the intimate views of a man in Mr. MacNaughton's position. Besides being an employer of many engineers, Mr. MacNaughton is a member of the Board of Control of the Michigan College of Mines.

VERMONT produces the largest quantity of tale, but the output of New York is of greater value. California ranks third in quantity and value and, notwithstanding the general decline in production elsewhere in the United States in 1918, it more than doubled its output of 1917. California produces some soapstone, but the bulk of its production is ground tale, mined in Inyo and San Bernardino counties, where it is more or less intimately associated with limestone and in part possesses a fibrous structure similar to that in much of the tale of the Gouverneur region, New York.

Mineral Production of Canada During 1919

By J. McLEISH

The War was probably the most effective agency in recent years in stimulating the development of natural resources. While it is tragic that this development should have been for the primary purpose of the destruction of life and of the long accumulated wealth of civilization, nevertheless, the result will be a rapid restoration of equilibrium and a future growth in the utilization of natural resources that will surpass all previous records. The explorations and investigations of the Canadian Department of Mines and of the Provincial Mining Bureaus have revealed some of the latent possibilities in the exploitation of Canadian mineral resources and have shown that Canada occupies an important place among the world's geographical groups as a potential source of mineral wealth.

Long before the greater production created by the War Canada had already become the world's principal source of nickel, asbestos, and cobalt, and an important producer of gold, silver, copper, lead, zinc, and a number of rare metals. Few countries possess greater resources of coal and the Canadian output of arsenic, chromite, feldspar, graphite, gypsum, mica, magnesite, pyrite, and tale, stands high in the records of world production. During the past four years under the stimulus of war demands, mineral production has increased from a total value of \$128,863,075 in 1914 to \$211,301,897 in 1918. Notwithstanding that much of the increased value indicated by this record was due to higher prices, many metals and minerals reached their highest recorded production in point of quantity during the latter year.

With the close of the War, however, came an almost immediate cessation of demand for nickel, copper, lead, zinc, and other metals, with large stocks accumulated. Mining of these metals either ceased for the time, or was greatly restricted and the year 1919 will probably be looked back upon as the transitional period between the demands of war for many products of the mine, and the ordinary requirements of industry supplemented by what we may appropriately term the demands of the period of reconstruction.

The rapidity of the change and its methods are being strongly influenced by the difficulties encountered in adjusting human relations. Production of gold, silver, and coal would have been much greater during the past year but for an actual shortage of mine-labor and the suspension of active operations for several months because of strikes. Definite records of production during 1919 will not be available for some time, but based on a broad survey of the results obtained the total value is estimated at \$167,000,000.

During the past six years the total values of mineral products have been:

	Metals	Non metallic	Total value
1914	\$39,380,619	\$69,476,156	\$128,863,075
1915	75,814,841	61,294,330	137,109,171
1916	106,319,365	70,882,169	177,201,534
1917	109,455,117	83,194,074	192,649,191
1918	114,549,152	96,752,745	211,301,897
1919	72,401,820	100,674,087	173,075,913

The mineral production by provinces for 1918 and 1919 was as follows:

	1918	1919
Nova Scotia	\$22,317,108	\$23,213,731
New Brunswick	2,141,017	1,075,006
Quebec	19,005,347	13,341,829
Ontario	94,694,093	65,842,826
Manitoba	3,220,424	2,816,565
Saskatchewan	1,019,781	1,118,055
Alberta	23,109,387	20,815,049
British Columbia	42,835,509	34,258,267
Yukon	2,355,631	1,963,965
Total	\$211,301,897	\$173,075,913

During the War the production of nickel was more than doubled; that of copper increased by nearly 60%; and zinc increased to five times its former output. Following the Armistice the prices of food and clothing continued to increase; the demand for such products could not abate as could the demand for metals of which accumulated stocks were for a time sufficient to meet current requirements. Silver and iron were two great exceptions for widely different reasons. However, stocks are evidently being absorbed rapidly and the rate of production is being increased as prices rise.

The value of the production of non-metallic products is largely governed by that of coal. The tonnage of coal produced in 1919 was 13,586,300 short tons, valued at \$54,051,720. The tonnage was less than that of 1918, but, on account of higher prices, the total value was only \$1,141,176 less than that of the preceding year.

Notwithstanding the progress that has been achieved in the development of Canada's mineral wealth, there are three great products—probably the most important upon which industrial activity is built—namely, coal, iron, and petroleum, for which Canada is dependent in large measure upon foreign supply. The total value of the imports of these products, much of the iron and steel in a manufactured form, and petroleum as refined oils, amounted in 1918 to \$286,115,000. Expressing the imports of petroleum as crude oil, and the iron and steel as pig-iron, the total would probably be not less than \$140,000,000. These figures indicate the great need for development of domestic resources, in order to effect the economic utilization of our Canadian coal, low-grade iron ore, and oil-shale; and they demonstrate the great necessity of intensive prospecting for higher-grade iron ores and for oil-fields.

COPPER AND NICKEL. Copper and nickel, followed by gold and silver, are the metals of first importance as producers of wealth in Canada. The nickel is derived from one main source, namely, the ores of the Sudbury

district. The other metals come from various localities, though the greater part of the silver is from the Cobalt district. The production of nickel in 1919 was 44,542,953 lb., which at 40c. per pound would be worth \$17,817,181, as compared with 92,507,293 lb., valued at \$37,002,917 in 1918. In 1914 the total production was 45,517,937 lb. About one-fourth of the production during the year has been in the form of refined metal, the refinery of the International Nickel Co. at Port Colborne having been in active operation throughout the year. The new nickel-refinery of the British America Nickel Corporation under construction at Deschenes, near Ottawa, is rapidly approaching completion and will be placed in operation early in 1920.

The price of nickel has not varied as greatly as that of other metals, either during the War, or subsequently. During 1918 the price in London varied from a maximum of £260 per long ton in May, to £195 per ton at the end of the year. In December 1919 the London price was from £215 to £220 per ton. The New York quotation varied from 45 to 40c. per pound during 1918, and in December of 1919 was 42c. per pound for ingots and 45c. for electrolytic. The production of copper during 1919 amounted to 75,124,653 lb., which at the average price in New York of 18.691c. per pound would be worth \$14,041,549, as compared with 118,769,434 lb., valued at \$29,250,536 in 1918. Even at this figure the copper production in 1919 was greater than that of 1914 or any previous year, and having in view the fact that the price fell from 26c. per pound in November 1918 to less than 15c. in March 1919, and the effect of labor difficulties in British Columbia, this record may be viewed as satisfactory.

In 1918 the production included 5,800,000 lb. from Quebec; 47,000,000 lb. from Ontario; 2,340,000 lb. from Manitoba; 62,860,000 lb. from British Columbia; and a little over 600,000 lb. from the Yukon district. In 1919 the production from Quebec, which is derived from the pyrite ores of the Eastern Townships was 2,691,695 lb. valued at \$1,445,577, and of that of Ontario, which comes from the Sudbury nickel-copper ores, was 24,361,934 lb., valued at \$4,443,489. The Manitoba production amounted to over 3,000,000 lb., as compared with something over 2,000,000 in 1918, and was derived chiefly from the Mandy ore deposits at Schist lake, north-west of the Pas. In British Columbia the production was 44,388,934 lb., valued at \$8,296,735, as compared with 62,956,681 lb., valued at \$15,482,560 in 1918. The production from the Yukon is estimated at 334,090 lb., valued at \$62,445, as against 618,878 lb., valued at \$152,663 in 1918, which were derived from the copper ores of the White Horse district.

Development operations at Copper Mountain by the Canada Copper Corporation, which have been in progress for several years have proved the existence of 10,000,000 tons of ore with an additional tonnage probable. This ore averages 1.74% copper, in addition to gold and silver, and compares favorably with the average ore now being mined at the Hidden Creek mine at Anyox. A

2000-ton mill is about completed, a railway eight miles long, connecting mill and mine, is under construction, as is also a power-line from Bonnington Falls. Both the last undertakings have been delayed by lack of labor and strikes, but are expected to be completed toward the middle of 1920. At Rossland active mining has, on the whole, been well maintained. The copper is now being recovered in the electrolytic refinery as refined metal. The drop in price from 26c. in November 1918, to 14 to 16c. in February, with practically no market in December and January, might easily have justified a more serious lessening in activity. But as the year progressed prices stiffened and rose to 22c. in July, though they fell again to 18½c. in December.

The continued development of larger orebodies at Hidden Creek, Britannia, and Copper Mountain; improvements in the treatment of the Rossland ore; the construction of a smelter in Northern Manitoba for the reduction of the ores from the Mandy and other mines; resumption of operation at full capacity at Sudbury; and the development of numerous lesser deposits warrant the expectation of increased copper production during the present year.

GOLD AND SILVER. The total production of gold in 1919 amounted to 767,167 oz., valued at \$15,858,749, as against 699,681 oz., valued at \$14,463,689 in 1918. This output, however, is still less than that of 1916 when a total of \$19,234,967 was obtained, and far below the output during the heyday of the Yukon, when in 1900 a maximum of \$27,908,153 was produced. In 1918 the production included \$2,118,325 from the Yukon district; \$3,624,476 from British Columbia, and \$8,516,299 from Ontario, with smaller amounts from Manitoba, New Brunswick, and Nova Scotia. The Yukon district produced 90,447 oz., valued at \$1,869,705, as against 102,474 oz., valued at \$2,118,325 in 1918. British Columbia's production of gold amounted to 165,319 oz., valued at \$3,417,447, as against 180,163 oz., valued at \$3,724,300 in 1918. The principal sources of gold in this Province are the gold-copper ores of Rossland, Phoenix, Anyox, and the Surf-Inlet mine in the Skeena district; the arsenical gold-ores of the Hedley mine, and gold ores from Sheep creek near Nelson, and from Lilloet, together with some alluvial deposits. A number of very promising undertakings are being developed in the districts near the coast and much interest has been centred in the Premier mine in the Portland Canal district in which a large tonnage assaying \$30 in gold and silver has been proved.

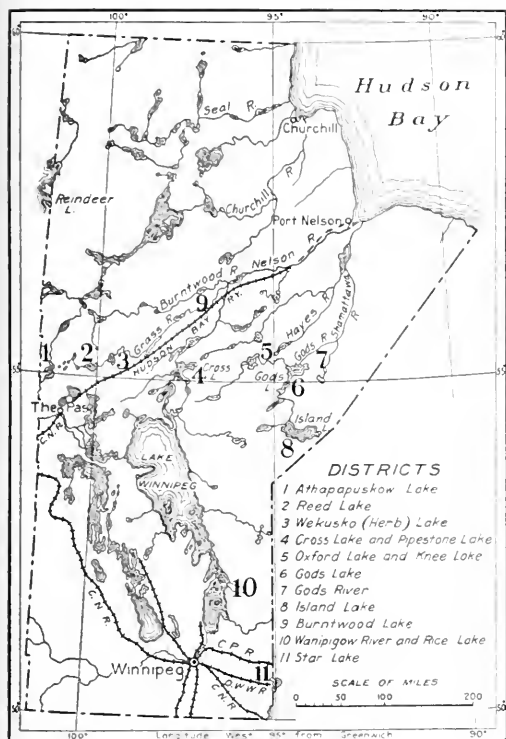

Manitoba produced 611 oz. compared with 1926 oz. in 1918 from the gold and copper ores of the Pas district, Northern Manitoba. Some spectacular finds made during the past year are attracting attention to the new districts in this Province.

Ontario's production in 1919 was 508,380 oz., valued at \$10,509,147, as compared with 411,976 oz., valued at \$8,516,299 in 1918, derived principally from the Hollinger, Dome, and McIntyre mines, with smaller contributions from the Lake Shore, Davidson, Kirkland Lake, and others. The 1919 production exceeded the record of

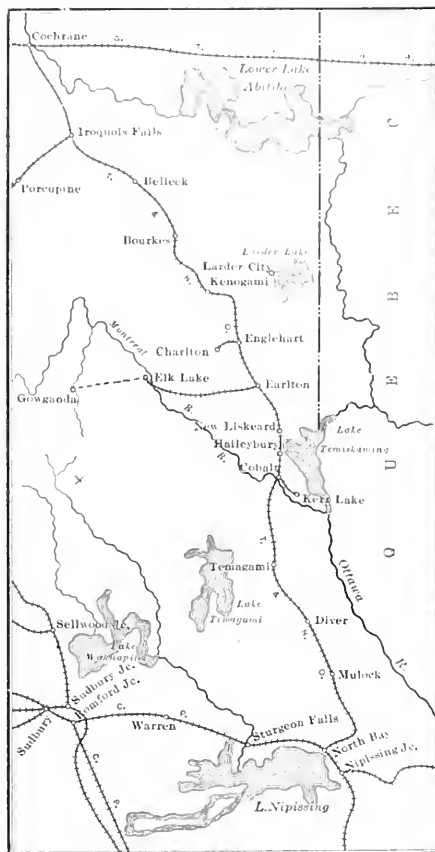

1916, which was the previous maximum. With decreasing costs of supplies and a more plentiful supply of labor greater production should be obtained. The wide extent of territory over which discoveries have been made and new gold-camps established, give excellent reason for anticipating that this Province will soon occupy a higher position among the gold-producing regions of the world.

Previous to 1908 the annual production of gold in Canada had exceeded that of silver. In 1908, with the rapidly increasing production from the new silver-producing district in Northern Ontario, the total value of silver produced exceeded that of gold and continued to

and 906,528 oz. or 5.8% was contained in blister copper. The production in Quebec amounted to 140,926 oz., as against 178,675 oz. in 1918; Ontario's production was 11,931,179 oz. or 76.1% of the total production of the Dominion. Manitoba produced 20,760 oz., as compared with 13,316 oz. in 1918. British Columbia produced 3,554,598 oz. valued at \$3,949,940, as against 3,921,336

MAP OF MANITOBA

MAP OF NORTHERN ONTARIO

remain in excess until 1914, when the growing production of the Porcupine and other Northern Ontario gold districts and decrease in the production of silver brought the value of the gold-output once more into first place. Largely because of the higher prices received for silver and the temporary restriction on gold mining because of high costs, the silver output was in excess in 1917 and 1918, also in 1919. The production of silver in 1919 is estimated at \$15,675,134 oz., valued at \$17,418,522, as compared with 21,383,979 oz., valued at \$20,693,704 in 1918.

Of the total production, 1,843,368 oz. or 75.6% was produced as bullion and refined silver; 2,925,238 oz. or 18.6% was estimated as recovered from ores exported;

and 906,528 oz. or 5.8% was contained in blister copper. The production in Quebec amounted to 140,926 oz., as against 178,675 oz. in 1918; Ontario's production was 11,931,179 oz. or 76.1% of the total production of the Dominion. Manitoba produced 20,760 oz., as compared with 13,316 oz. in 1918. British Columbia produced 3,554,598 oz. valued at \$3,949,940, as against 3,921,336

oz., valued at \$3,794,755 in 1918. The Yukon produced 24,671 oz.; in 1918, 71,915 ounces.

LEAD AND ZINC. Lead and zinc are obtained chiefly from British Columbia. Ore shipments materially declined during the early months of the year. Considerable dissatisfaction was manifested by a number of shippers with the prices and purchasing conditions offered by the Trail smelter, the only lead-smelter in Western Canada. A special committee of investigation was appointed, which was given full access to the books and records of the smelting company. Evidence was also solicited from shippers. The conclusion of the committee was that the rates imposed by the smelter's lead-schedule 'B', at the time of its going into effect, were reasonable. Many

shippers of lead, however, sought markets for their ore in the United States and during the first nine months of the year lead ore was exported containing over 10,000,000 lb. of lead.

The production of lead in 1918 was 51,398,002 lb. of which 47,594,328 lb. was obtained from British Columbia and the remainder chiefly from Ontario and Quebec, with a small production from the Yukon district. Of the total, 32,782,000 lb. was recovered as bullion, the rest being lead contained in ore exported.

Production of zinc in 1918, including actual recoveries of refined zinc at the Trail refinery and estimated recoveries from ores and concentrates exported, was 35,083,175 lb. Of this amount 2,802,928 lb. was credited to Quebec province and the remainder to British Columbia.

The production of lead in 1919 is put at 43,895,888 lb., valued at \$3,057,788, as compared with \$51,399,002 lb., valued at \$4,754,315 in 1918. The production of zinc during 1919 amounted to 31,738,859 lb., valued at \$2,328,998, as against 35,083,175 lb., valued at \$2,862,436 in 1918. The prices of both metals have been considerably less than during the last year of the War, that of lead having averaged about 5.73c. (New York) and of zinc 7.03c. in 1919, as compared with 7.4 and 8.16c. respectively in 1918.

The prospects for the future are, however, encouraging. The zinc plant at Trail is said to be operating on a much more efficient basis; large resources of ore are assured in the Sullivan mine and the Consolidated Mining & Smelting Co. that operates both mine and smelter, is reported to have successfully arranged for the marketing of its surplus zinc in Europe. This company probably has in its own mines sufficient developed ore to supply the full capacity of the Trail plant. Threatened competition of buyers from smelters in the United States would without doubt be welcomed by the independent mine operator of the Kootenay district.

OTHER PRODUCTS. Among other ores and mineral products for which particular demand was created by the War, and to the production of which Canada was able to contribute important quantities were: cobalt, molybdenum, arsenic, asbestos, chromite, magnesite, graphite, and pyrite. Returns from the operators are incomplete, but the exports of molybdenite were 113,520 lb., valued at \$84,228. Most of the production was derived from the Quyon, or Marsh mine near Ottawa. In the Black Lake and Richmond districts, Eastern Townships, four firms, with another to report, show the shipments of chromite to have been 5266 tons valued at \$224,971. In 1918 the shipments were 21,994 tons of ore and concentrates valued at \$867,122.

Canada's production of pyritic ores greatly increased during the War, rising from 158,566 tons in 1913, to 416,649 in 1917. The total shipments in 1919 were 177,487 tons valued at \$522,704. In 1918 the shipments were 411,616 tons valued at \$1,705,219. The production of arsenic in 1919 was 2662 tons of arsenious oxide and approximately 530 tons of arsenic in concentrates valued at \$508,770. In 1918 the production was 2482 tons of arsenious oxide and 1078 tons of arsenic in concentrates.

The shipments of graphite, which in 1917 reached the high point of 3714 tons valued at \$402,892, in 1919 fell to 1322 tons, valued at \$92,837, almost all from Ontario.

PETROLEUM. More than 90% of the production of crude petroleum in Canada is still obtained from the old oil-fields in southern Ontario, which have now been producing for 58 years. This production has been supplemented during recent years by a small annual production from New Brunswick and Alberta. The total production of crude oil from these fields in 1919 was 240,970 bbl. of 35 imperial gallons having a value of \$744,677, as compared with a total production in 1918 of 304,741 bbl. valued at \$885,143.

Accidents at Metallurgical Plants

In ore-dressing plants machinery was responsible for 40% of all fatalities and 18.17% of all injuries during 1918. Similar figures for smelting plants are much smaller for the reason that more machinery is used in ore-dressing plants than at smelters and the men are usually in closer contact with the machinery, as, for example, at jigs, tables, stamps, rolls, and crushers. There are many revolving shafts, a large number of which have projecting keys, moving belts, wheels, and cams within the reach of the operator. The machinery at smelting plants is usually confined to the power-house, where the blowers, engines, and dynamos are placed, and to overhead cranes, which are not a source of much danger to smeltermen.

At ore-dressing plants 17.14% of the fatalities were due to falls of persons, whereas at the smelters the fatalities due to falls of persons represented 9.52% of the total. Fatalities due to electricity represented 7.14% at smelters and 8.57% at ore-dressing plants. Haulage systems caused 30.96% of the fatalities at smelting plants and 14.29% at ore-dressing plants. Of the non-fatal injuries at ore-dressing plants 5.58% were due to haulage, whereas at smelters 9.58% were due to that cause. At smelting plants burns from hot metal and slag claimed 9.52% of the fatalities and 19.13% of the non-fatal injuries.

The number killed in the ore-dressing plants was 35, or 1.55 per thousand 300-day workers employed, as compared with 47 in 1917, when the fatality rate was 1.93. The total number of injuries was 3142, as compared with 2952 in 1917. In 1918 the number of men killed at smelting plants was 42, or 0.92 per thousand 300-day workers, as compared with 1.05 per 1000 in 1917. There were reported 6743 injuries, or 148.40 per 1000. Auxiliary works are intended to include machine-shops, carpenter shops, yards, and general construction, all of which, though forming part of the metallurgical plants, should not be included in the actual operating departments. The returns for 1918 show 18,044 men employed, with 17 fatalities and 2808 injuries. Reduced to the 300-day basis, this represents 20,111 workers, with a fatality rate of 0.85 and a non-fatal injury rate of 139.63 per 1000. A large proportion of non-fatal injuries was due to hand tools, falling objects, and falls of persons.—U. S. Bureau of Mines.

Formulas for Determining the Tonnage of Products From Metallurgical Operations

By A. H. HELLER

THREE-PRODUCT FORMULA FOR MILL-WORK. In many concentrating plants, especially in those working on complex ores, more than one product, besides the tailing, is made. In some plants the products are run into settling-tanks, or boxes, where a close estimation of daily tonnage may be obtained by measurement. This is true of many mills where gravity concentration only is used. In other plants, the concentrate is run into containers, such as thickeners, where it is practically impossible to measure the daily output; this is done where flotation is employed, and especially where selective flotation is in use. In operations where three products are made—for instance, two concentrates and a tailing, or one concentrate, a tailing, and a middling that may be rejected or stored for future treatment—it is often necessary to determine the daily tonnage of these products, in order to obtain a true idea of current metallurgical results. For example, if from a complex lead-zinc ore a lead concentrate and a zinc concentrate are made, and a maximum recovery of the lead is sought, even at a sacrifice of zinc, the result of one day's operations may show a high lead content in the zinc concentrate, yet the former may show the highest recovery of lead in the lead concentrate, owing to a smaller tonnage of zinc having been obtained. For this reason, it is necessary to know daily the tonnages of products. Having given the assays of mill-feed and products, and the tonnage of mill-feed, I have derived the following formula for determining the daily tonnage of concentrates and tailings; it should prove useful to many metallurgists having problems similar to those just mentioned.

The time consumed in making calculations by this method is not much more than that required to determine the tonnage of a single concentrate by the well-known formula:

$$\text{Tons of concentrate} =$$

$$\frac{\text{Tons of feed (feed assay - tailing assay)}}{\text{Concentrate assay - tailing assay}}$$

Assuming that the following are known:

Tons of mill-feed; and assay of each of two metals in (1) heading, (2) tailing, (3) 1st concentrate, and (4) 2nd concentrate.

If we let V represent one metal,

W represent another metal

A = V in 2nd cone. \times W in tailing

B = V " tailing \times W " heading

C = V " heading \times W " 2nd cone.

D = V " 2nd cone. \times W " heading

E = V in heading \times W in tailing

F = V " tailing \times W " 2nd cone.

G = V " tailing \times W " 1st cone.

H = V " 1st cone. \times W " 2nd cone.

K = V " 2nd cone. \times W " 1st cone.

L = V " 1st cone. \times W " tailing

M = V " 1st cone. \times W " heading

N = V " heading \times W " 1st cone.

x = tons of 1st concentrate

y = tons of 2nd concentrate

z = tons of tailing

$$\text{Then } x = \frac{(A + B + C - D - E - F)}{Y} \times \text{tons of heading}$$

$$\text{where } Y = A + G + H - K - L - F$$

$$\text{and } y = \frac{E + G + M - N - B - L}{Y} \times \text{tons of heading}$$

$$z = \frac{D + N + H - K - C - M}{Y} \times \text{tons of heading}$$

If we have the assays of each of three metals in the heading, concentrates, and tailing, a double check is available. For instance, if on a copper-iron-zinc ore, a zinc concentrate and a copper concentrate are made, and the assay of copper, iron, and zinc be known for the heading and for all the products, the tonnages may first be determined by using assays for copper and zinc, checking them by using those for copper and iron, and re-checking these by using the assays for iron and zinc. If a close check is not obtained, it is due to errors in sampling or assaying.

I have derived the above formula in the following manner:

Let tonnage to mill = 1

x = tons 1st concentrate

y = tons 2nd concentrate

z = tailing in tons

V = one metal

W = another metal

a = assay of V metal in heading

b = " " " " " 1st concentrate

c = " " " " " 2nd concentrate

d = " " " " " tailing

e = " " W " " heading

f = " " " " " 1st concentrate

g = " " " " " 2nd concentrate

h = " " " " " tailing

$$\text{Then: } x + y + z = 1$$

$$bx + cy + dz = a$$

$$fx + gy + hz = e$$

Solving the above equation of three unknowns, we have:

$$\begin{aligned}x &= \frac{ch + de + ag - ce - ah - dg}{ch + df + bg - ef - bh - dg} \\y &= \frac{ah + df + be - af - de - bh}{ch + df + bg - ef - bh - dg} \\z &= \frac{ce + af + bh - ef - ag - be}{ch + df + bg - ef - bh - dg}\end{aligned}$$

As the above formula is worked out for one ton of mill-feed, the tonnage of the products may be obtained by multiplying the values of x , y , and z by the number of tons milled.

As there is a duplication of multiplication in the above, for simplicity, I have let

$$\begin{array}{lll}A = ch & E = ah & K = ef \\B = de & F = dg & L = bh \\C = ag & G = df & M = be \\D = ce & H = bg & N = af\end{array}$$

in the equations for x , y , and z in the derived formula.

CALCULATIONS FOR DETERMINING THE TONNAGE OF PRODUCTS FROM SMELTING OPERATIONS. In practically all smelting operations there are four products, namely, a matte or other metallic product, flue-dust, slag, and a gaseous product. The formula for determining the tonnage of these is longer than that given for three-product mill-work. However, in smelting it is not possible to obtain a daily estimate of the tonnage of the products, owing to the length of time that the material remains in course of treatment. The effects of a change in the charge on a furnace may not become apparent for a day, whereas in mill-concentration a change in the character of feed will be noticeable within a few minutes. For this reason it is advisable to determine the tonnage of products from smelting only at intervals of from 15 to 30 days.

At most smelters the quantity of matte, or metallic product tapped, is determined accurately by direct weighing, but it may not represent the actual amount of matte made, since, owing to a change in the grade of ore, or a change in the matte-level in the furnace, the quantity tapped may not represent that actually formed in the furnace. A fairly accurate weight of the slag can be determined when slag is skimmed into cars of known capacity, but if the slag is granulated or skimmed directly into dams, any estimation would be inaccurate. Few plants are able to estimate directly the amount of flue-dust produced. The plants that have efficient systems for catching dust are few, and those that have, probably do not estimate the tonnage of flue-dust or fume per lot of charge. The tonnage of gaseous product can only be obtained by calculation.

To determine the tonnage of the four products mentioned above, the weight of charge to the furnace must be known, together with reliable composite assays of charge, matte or metallic product, slag, and flue-dust or fume. There are various ways of obtaining a fairly good sample of the flue-dust or fume leaving the furnace; these are known to every smelter-man.

The assays of three metals, besides sulphur, in the charge and products must be known. The following has

been my method of determining the products obtained, and I have always found that my calculated matte checked my actual production within reasonable limits.

Let tons charged to furnace = 1

$$\begin{array}{llll}b = \text{assay of 1st metal in matte} \\e = \text{“ “ “ “ “ slag} \\d = \text{“ “ “ “ “ flue-dust} \\f = \text{“ “ “ “ “ 2nd “ “ matte} \\g = \text{“ “ “ “ “ slag} \\h = \text{“ “ “ “ “ flue-dust} \\j = \text{“ “ “ “ “ 3rd “ “ matte} \\k = \text{“ “ “ “ “ slag} \\l = \text{“ “ “ “ “ flue-dust} \\m = \text{“ “ “ “ “ 1st “ “ charge} \\n = \text{“ “ “ “ “ 2nd “ “ charge} \\o = \text{“ “ “ “ “ 3rd “ “ charge} \\x = \text{tons matte} \\y = \text{“ “ slag} \\z = \text{“ “ flue-dust}\end{array}$$

$$\text{Then: } bx + cy + dz = m$$

$$fx + gy + hz = n$$

$$jx + ky + lz = o$$

Solving the above equation of three unknowns, we have:

$$\begin{aligned}x &= \frac{mgl + cho + dnk - dgo - cnl - mfk}{bgl + chj + dfk - dgj - cfi - bhk} \\y &= \frac{bnt + mhj + dfo - dnj - mfi - bho}{bgl + chj + dfk - dgj - cfi - bhk} \\z &= \frac{bgo + cnj + mfk - mgj - cfo - bnk}{bgl + chj + dfk - dgj - cfi - bhk}\end{aligned}$$

As before the values of x , y , and z must be multiplied by the number of tons charged to the furnace.

Having obtained the tonnage of products according to the above formulas, and knowing the sulphur analysis of charge and products, the difference between the sulphur content (in pounds) of charge, and the total of the sulphur contents of the products, would be the amount driven off as gas. This sulphur is exclusive of any sulphur in the form of SO_2 , which has combined with any oxide to form solid sulphate, the latter being included in the sample of flue-dust or fume and consequently in the tonnage of flue-dust, or fume.

CONTINUOUS breathing of the very fine sharp particles of quartz that constitute the dust in many metal mines produces a mechanical injury to the lungs, causing a disease peculiar to the mining industry, and known as miners' consumption, miners' phthisis, miners' asthma, silicosis, or more accurately pneumoconiosis due to siliceous rock dust. A man engaged underground should carefully avoid working in the dust.

IT IS REPORTED that the Italian government is arranging to purchase the large Abruzzi and Tannium bauxite deposits, to be worked by the Government. The probable intention is to manufacture aluminum wire to be used in place of copper in the electrification of the Italian railways. Italy's resources of bauxite are sufficiently extensive to permit production on a large scale.—U. S. Bureau of Mines.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

MILL AT DUNCAN IS COMPLETED.

BISBEE.—The sinking of the Nighthawk shaft from the 650 to the 750-ft. level was completed last week. A station has been cut on the 750-ft. level and preparations are being made to drift and prove the orebodies developed on the upper levels. It is reported that 40 ft. of oxide ore averaging 6½% copper was cut on the 550-ft. level. Two cars of this ore have been shipped. The Shattuck Mining Co. has commenced sinking the shaft from the 900-ft. level to the 1100-ft. level. A 3000-ft. Nordberg compressor is being installed at the Denn property and it is expected to be in operation by the end of April. Drifting on the 1800-ft. level has been commenced. It is reported that the Calumet & Arizona Copper Co. is to explore thoroughly by drilling the limestone below the 1500-ft. level of the Briggs mine, which is estimated to be 1000 ft. thick.

DUNCAN.—The \$150,000 mill of the Duncan Mining & Milling Co. at Mount Royal 10 miles from Duncan has been completed. It is announced that this mill is of sufficient capacity to handle custom ores in addition to those mined by the company.

JEROME.—Shipments at the rate of five tons of copper ore per day are now being made by truck from the Franco-American mine to the Humboldt smelter. This ore is said to assay 40% copper and 17 oz. silver. The Jerome Prescott Mining Co., which has taken over the old Sanders group of 32 claims, has started development work upon one claim in which there are excellent prospects of gold. The present inclined shaft is to be deepened.

KINGMAN.—It is reported that French capital is financing the Middle Hackberry Co., \$50,000 having been raised to develop the mine. Development work is to be commenced immediately.

A company to take over the Pay Roll mine at Chloride has been organized.

The Arizona Buttes Mines Co. was formally taken over by the Kingman Consolidated Mines Co. on April 1. A new boarding house and two bunk-houses are under construction at the camp near the tunnel. A larger compressor is to replace the old one, which will be moved to the Banner mine.

The Hackberry Consolidated Mining Co. and the Senate Silver Mining Co. have been consolidated. Work has been discontinued on the Senate Silver property and

the development from the Hackberry Consolidated shaft which has been planned is now under way.

PARKER.—The Mammoth Copper property, 10 miles east of Parker, is to be drilled. Copper ore, assaying as much as 10%, has been developed in a 13-ft. vein. The vein is at present opened by a 178-ft. shaft and 2000 ft. of tunneling. The work will be done under the direction of W. M. Boyce, while E. W. Brooks and Walter H. Weed are consulting engineers.

TOMBSTONE.—A Colorado company has taken a bond and lease on the Cummings-Wolcott-Cowan properties in the Courtland district. Machinery is being repaired preparatory to unwatering the mine.

COLORADO

OPERATORS AT CRIPPLE CREEK AWAIT ACTION ON PROPOSED EXCISE LAW.

CRIPPLE CREEK.—Gold-mine operators in the district, anticipating enactment by Congress of the law providing an excise tax on jewelry and manufactured gold, are

OLD DOMINION PLANTS AT GLOBE, ARIZONA

playing a waiting game. Production has been reduced to a payroll basis, and except for the corporations with a cash reserve, development is at a stand-still. April, being the first month of the second quarter, is usually a dividend month, but to date, excepting for the regular monthly dividend of the Golden Cycle company of 10 cents per share, payable on April 10, and the reduction from 2 to 1½ cents, or from \$60,000 to \$45,000 by the Portland company, no other dividends have been declared. Miners are leaving the district as rapidly as possible, and it is generally believed another exodus will

accruing following the settlements of accounts if the April pay-checks will supply railway fare. Conditions confronting the gold industry here need no further comment and unless Congress acts promptly, production will apparently continue to decrease.

T. R. Countryman, consulting engineer to the War Eagle Consolidated Mines Co., in reporting connection made on April 2 from the Blue Flag workings with the Moffat tunnel, stated that the "ventilation was thorough". The entire tunnel and Blue Flag workings are completely ventilated with pure, fresh, cool air. The draft is so strong that a carbide-lamp cannot be kept alight in the drift. The engineer further reports a streak of black sulphide in the east wall, more than six inches thick assaying \$25 in gold, with a width next to it of one foot assaying \$19.40. This is in addition to 20 in. of ore opened in the drift.

The Blue Flag Gold Mining Co., now that the contract for connection with the Moffat tunnel is completed, will continue development of its Raven Hill properties lying north-west of the Cresson mine. Carpenters are at work framing mine-timbers and the head-frame is to be raised. New cables have been delivered and the skip and other equipment are on the way from Denver. The bottom level of the Blue Flag is now 1417 ft. deep, with elevation at the collar of the shaft 9019 ft. On the 12th level, east, a good formation has been entered, with some gold content. In the south drift the ore is of milling grade, with conditions improving with each round. Cross-cutting and drifting is to be continued at both the 12th and 14th levels until orebodies known to exist east and west of the main shaft are ent.

LEADVILLE.—Exclusive of the Down Town mines, the Ibex and Yak tunnel property, more than 50 mines are again under active development, on company account or by lessees. Production necessarily is materially increased. The samplers report more ore coming in, while the fourth furnace of the smelter is now in operation.

Among the properties to resume soon are the Rattling Jack, adjoining the famous Little Jonny, and the Hartford, O'Donovan, Rossa, and Peoria Boy, under lease to the Leadville Leasing Co. The Continental Chief is to be electrically equipped and will be in shape to operate by the end of the month. The National Development company of Chicago is making preparations to start work on the Big Chicago, Ready Cash, Cora May, and the Auroras 1 and 2, in the vicinity of Big Evans gulch. Five claims near Kevin mountain, owned by W. G. Parker, have been secured under bond and lease by the National Development Co., and work will start in earnest with the disappearance of snow.

MICHIGAN

WOLVERINE TO DEVELOP NEW PROPERTY.

CALUMET.—The adoption of a policy of extension on the part of the Wolverine corporation has excited interest in Calumet. Six years ago the proposition was made to the Wolverine corporation but the management at

that time did not look with favor upon any scheme calling for the purchase of additional territory, taking the stand that the business of the company was to mine out such territory as it owned and then to quit. A tract of 480 acres, owned by the St. Mary's Mineral Land Co., the Douglass-Shelden interests, and the Union Land company is involved. The problem of mining could be worked out along the lines of the re-hoisting scheme which the Calumet & Hecla now has in successful operation handling the 'five forties' from the bottom of the Red Jacket shaft, and which will be followed out in the further development of the Calumet conglomerate lode from the 81st level. There would be less than half a mile of dead territory to go through, although the shaft would have to be put through some South Kearsarge territory. This belongs to the Osceola Consolidated company, but it is believed that there would be no difficulty in making satisfactory arrangements with that company. If not, the shaft might be sunk through the foot-wall of the lode. The fact that engineers of the two mining companies, Osceola and Wolverine, are conferring is considered significant. Wolverine shareholders are heartily in favor of any scheme which gives promise of prolonging the life of the company.

Houghton.—Practically every mine in the Michigan copper district got out a larger production in March than in February. Yet the figures do not show any material increase in the output of refined copper and the total of the district continues at 60% of normal and less than 50% of the possible output provided there were sufficient labor. Osceola produced 50,000 tons in March, compared with 49,000 in February. Of this amount 12,000 came from the old Osceola mine and 38,000 from the Kearsarge branch.

Almeek produced 68,000 tons during the month, a little less than in February. The Almeek was one of the few mines that showed a good output in February. Centennial produced 7000 tons in March as against 6525 tons in February and 7500 in January.

Allouez showed a substantial betterment in March increasing from 14,231 tons in February to 20,500 tons in March. Isle Royale kept her own three-head stamp-mill running full time in March and sent 2880 tons to the custom mill in addition. Superior got out five cars and La Salle ten cars, all in the course of development operations which are continuing at these properties with practically nothing new revealed.

MONTANA

DEVELOPMENT OF THE EDITH MAY VEIN IN THE NORTH BUTTE MINE.

BUTTE.—The North Butte Mining Co. has picked up the heavily mineralized section of the Edith May vein on the 3200-ft. level. Drifting for a distance of 50 ft. east opened a width of 15 ft. of ore averaging 6.2% copper and 3.5 oz. silver per ton. Easterly, on the level above, ore averaging 1½ ft. wide with an assay value of 21% copper and 4.5 oz. silver has been opened. To the west

on this same level 32 ft. of drifting was in ore of an average width of 2½ ft., assaying 7% copper and 3.5 oz. silver. Operations are being concentrated on the 3100-ft. level in an endeavor to pick up the high-grade ore developed on the 3200-ft. level in the Edith May vein.

Production at the Butte & Superior for March from 43,000 tons of ore milled amounted to 10,500 tons of zinc concentrate and 150 tons of lead concentrate. The zinc recovery was 11,150,000 lb., while the total silver in the ore was 210,000 ounces.

The Clark interests, operating the Timber Butte mill and the Elm Orlu mine, have contracted for \$1,500,000 of insurance on the lives of 1500 employees. The premiums are to be paid by W. A. Clark himself. The

A high-grade optical glass will be made from the mineral.

NEIHART. Production records are being established by many of the mines here. A New York syndicate has taken over the Florence mine from E. A. Shaw and Allen Pierce of Great Falls. The Neihart Consolidated Silver Mining Co. is now a steady shipper with its Hartley mine as the leading producer. Electrical equipment has been installed at the Broadwater mine and sinking of the shaft commenced.

NEVADA

RICH ORE AT MONTEZUMA SILVER MINES.

MONTEZUMA.—At the present depth of 296 ft. the shaft of the Montezuma Silver Mines Corporation has been in

CONVEYOR AND TRIPPER. ANACONDA COPPER COMPANY'S LEACHING PLANT AT ANACONDA

amount of insurance ranges from \$500 to \$2500 depending on the length of service.

The February production of the Barnes-King Development Co. was as follows: from the North Moccasin mine, 1799 tons, yielding \$7.63 per ton; the Gloster mine, 1225 tons, yielding \$9.10 per ton; and the Shannon mine, 2209 tons, yielding \$8.42 per ton; making the total production 14,377 tons.

The Butte & Plutus Mining Co. has increased its capitalization to \$1,000,000. The company's Mapleton shaft is being sunk to the 250-ft. level from which the main Norwich-Mapleton vein will be cut. Continued sinking to the 400-ft. point is planned so as to cut the rich Norwich vein at that level. This vein is 12 ft. wide in the upper workings with excellent silver content.

SPRINGDALE.—The Pittsfield Mining Co. of Billings is preparing to exploit a large deposit of crystallized calcite.

ore continuously for 45 ft. and general conditions are the same as when the find was made at 251 ft. The lowest assay secured from the entire bottom of the shaft has been \$50 and at 296 ft. the rich seam has reached the maximum width of 40 in. An assay of \$212 in silver and lead was secured from this 40-in. width. The copper and zinc content is good. The average width of the vein as exposed in the shaft is from 4½ to 5 ft., but blasts into the irregular foot-wall have opened high-grade ore and when the 300-ft. point is reached a cross-cut will be driven into this wall. Drifts will be driven at 200 and 250 ft. when compressors now at Goldfield reach the mine. Drifts to be driven at 300 ft. will be the first in the ore-shoot. Only a few years ago the claims of the Montezuma Silver were sold for taxes and the company paid \$2000 to redeem them. For years Arthur Cooper, superintendent, fought a remarkable battle to continue work on the claims, as

there have been few times when the company was not in financial straits or other difficulty. In part payment for his work he has taken 25,000 shares of stock in the company and miners employed shortly before the find was made were paid partly in stock, which has become valuable.

TELE CANYON.—Fourteen men are employed by the holders of the option on the Ingalls. These men formerly were employed at the Gibraltar, where work has been stopped. The Gibraltar and the Ingalls are controlled by the same interests.

QUARTZ MOUNTAIN.—Eastern interests are negotiating to take over the Edwards group, on which the holders of a 5-year bond and lease recently opened on the surface what is reported to be a promising vein of gold ore.

GOLDFIELD.—A promising body of rich ore has been opened in the Cracker Jack lease on the Florence and it is expected that within 10 days the management will make a statement of conditions. The ore is being blocked out and it is reported that a considerable tonnage has been broken. The tunnel being driven by the Five to One far south of the Florence is over 350 ft. long and for the last 125 ft. it has been in tale containing seams of quartz from which good pannings are obtained. It is thought the vein will be cut within 50 ft. The Florence company has connected the west cross-cut on the seventh level with the old Moore lease shaft, which so improved the air in the cross-cut that drifting can be started.

ARROWHEAD.—At 45 ft. from the shaft the west drift on the 100-ft. level of the Arrowhead for 35 ft. has been in ore assaying \$125 over a width of 3 ft. The vein is 5 ft. wide. A raise is being driven from the west drift on the 165-ft. or bottom level, and when this has been completed sinking of the shaft will be resumed and continued to the 300-ft. point. The ore-shoot east of the shaft has been opened for a length of 65 ft. and a raise between the bottom and the 100-ft. level is in ore of high shipping grade.

UTAH

SALT LAKE CITY AS A SMELTING CENTRE

SALT LAKE CITY.—Salt Lake City took first rank as an ore-smelting centre during 1919, according to a compilation showing the tonnages treated by the smelting plants of North America, prepared by H. M. Adkinson. Taking into consideration both copper and lead-silver capacities for 1919, the Salt Lake district totaled 4,430,000 tons, of which 1,830,000 tons represents lead-silver and 2,600,000 tons copper furnaces. The furnace capacity at Douglas, Arizona, the nearest rival, was reported as 3,970,000 tons, while Anaconda's capacity was 3,580,000 tons. All four of the smelters in this vicinity are in operation; the silver-lead plants being the Murray and Midvale smelters, the exclusively copper smelter being the A. S. & R. plant at Garfield, while the Tooele smelter of the International Smelting & Refining Co. handles both copper and lead-silver ores.

BINGHAM.—On April 6, all the mining companies

posted notices, announcing that wages would be increased 25c. per shift, effective April 1. Since last July, the wages paid here to underground employees have been 25c. per shift less than those paid to similar employees in the other camps of this State. This increase, therefore, puts all wages paid in Utah mines on the same base scale. Under the new scale, machine men and timbermen will receive \$5.25 per day; miners, \$5; muckers, \$4.75; and mine laborers, \$4. On the following day, the various smelters and milling plants in Salt Lake valley posted notices announcing a similar increase.

ALTA.—An unfortunate accident occurred here on the morning of April 5, when a large snowslide swept down from the property of the Sells Mining Co., and carried everything before it on the property of the Wasatch Mines Co. One miner, the steward at the auxiliary plant of the Wasatch company, and his wife were killed. For years it has been the belief of the Wasatch mine officials that the buildings at the auxiliary plant were absolutely safe from slides. They were situated on a knoll and from one direction they were protected by a gulch and then by a large clump of trees. The rushing mass, with a roar heard for miles, crossed this gulch and swept up the incline, tearing immense trees from their roots and reducing the boarding and bunk-house to kindling. It then switched its course and passed directly between several other buildings, including the compressor-house, transformer-station, powder-house, and machine and blacksmith-shop, which were not damaged. This is the third snowslide to occur in this district within 30 days; the first having been on March 7, near Lake Solitude, and the second on March 20 near the Peruvian mine. In these two slides four men were killed, making seven lives that have been lost in the three slides.

PARK CITY.—Another shipment of 'premium' spelter was made by the Judge Mining & Smelting Co. during the week ending April 3. Ore shipments for the same period totaled 2095 tons, as compared with 2206 tons for the previous week. The Ontario Silver shipped 616 tons; Silver King Coalition, 605; Judge M. & S., 440; Daly-West, 233; Daly, 108; and Naildriver, 60 tons.

As an inducement to steady work, the Judge company is now paying a bonus to men working thirteen consecutive days. Every employee who puts in thirteen days is paid for fourteen days work. It is likely that other companies here will adopt a similar plan, as the present scarcity of good miners is a great drawback. The new pump at the Iowa Copper has been placed and was started on April 4. It is being used to unwater the shaft and drift, and within a short time, work in the face of the drift will be resumed. This property is now equipped for extensive work. Owing to the deep snows, eleven days time was required to get the new pumping equipment from the station to the mine, the snow being six feet deep in places.

J. B. Allen, manager of the Glenallen property, reports that a new orebody was struck on March 31. Sufficient work has not been done to determine the size of the vein, but samples so far taken indicate first-class ore.

EUREKA.—Ore shipments from the Tintie district for the week ending April 3 totaled 151 cars, a decrease of 13 from the previous week. Inclement weather and bad roads were, in part, responsible for this decrease. Influenza at Mammoth, a section of the camp which has been immune to past epidemics, seriously checked operations at several of the adjacent mines. The Chief Consolidated shipped 39 cars; Tintie Standard, 20; Dragon Con., 20; Eagle & Blue Bell, 11; Iron Blossom, 10; Centennial-Eureka, 8; Gemini, 7; Mammoth, 6; Grand Central, 6; Victoria, 6; Colorado, 5; Bullion Beck, 3; Empire Mines, 3; May Day, 2; Ridge & Valley, 2; Swansea, 2; Alaska, 1.

During the past week, prominent mining operators of

tem would be more efficient in affording effectual action in case of emergency.

The shaft at the North Beck Mining Co.'s property has reached a depth of 1620 ft. Sinking has been discontinued, and miners are now cutting a large station on the 1600-ft. level, which is the point selected by E. J. Raddatz, manager, for prospecting. This company owns a large tract of ground which is just north of the town proper. Mr. Raddatz is also developing the Victoria Gold Mining Co. property, adjoining the North Beck, and the main inclined shaft, which was sunk to a depth of 500 ft. a few years ago, is being deepened.

During 1919, but little progress was made at the Colorado Consolidated mine, which in by-gone days was the

THE TINTIE STANDARD MINE, IN THE EAST TINTIE DISTRICT, UTAH

this district met with members of the Eureka volunteer fire department, and a plan was formulated whereby the firemen, many of whom are miners, will take special training in mine-rescue work. The mining companies will supply the equipment and will pay a competent man to train those selected to take the lead, paying the firemen for the time they spend in training and in carrying out rescue work. The fire-department apparatus will probably be used in case of serious mine accidents and, in this manner, the trained men could be sent to almost any mine in the district within a few minutes' time. Only the mines of Eureka, Mammoth, and Silver City will be interested in the proposition which has been submitted to the department, such properties as the Tintie Standard and others in the eastern part of the district being too far away from Eureka to participate in such an arrangement. The Tintie Standard will likely secure its own equipment and keep a number of men properly trained. Heretofore each mine has had its own 'safety-first' department, but the operators feel that a co-operative sys-

tem would be more efficient in affording effectual action in case of emergency. The value of the ore shipped was \$107,435. According to the annual report, the revenue of the company was spent on exploration work which did not give satisfactory results, and such work was discontinued at the close of the year. The development work done during 1919 was undertaken primarily for the purpose of determining geological conditions, which it was hoped would be of value in further search for new orebodies. The mine is now being worked under the leasing system, cleaning up old stopes.

WISCONSIN

REVIEW FOR MARCH.

PLATTEVILLE.—March carried much of disappointment in it for zinc-operators. Weather adversely suited to output, an acute scarcity of labor, and unsatisfactory offerings for ore featured the month. The spring break-up was long deferred and roads were so wretched in some districts that shipments were discontinued. The result is a large accumulation of unsold milled ore, which may in

the end prove a benefit to sellers, should a higher market develop. An acute scarcity of shovelers found owners and managers seeking other expedients, and this drawback toward more production will before very long have been obviated to a large extent. Negroes have been imported into the district for work as muckers and trammers and two of the larger operating concerns have purchased mechanical shovels for which strong claims are made on the ground of efficiency. One machine, the invention of a miner, will load, with one man in control, a 3-ton car in three minutes. It is made to work by compressed air, in drifts of any dimension that will carry the machine. The satisfactory use of this machine at three mines in the field will no doubt encourage a general demand. The chief drawback to a higher output, however, is found in the offerings submitted by purchasers for all grades of zinc ore. The base price for high-grade zinc ore the first week in the month was nominal at \$52 to \$54 per ton, according to the prices paid for high-grade blende under contract sales. This price held until the third week when the base was approximately \$52 per ton. The Mineral Point Zinc Co., through its purchasing department, upset rules by bidding up one lot of prime Western ore, about 250 tons, to \$60 per ton. This concern, regarded as one of the largest smelter organizations in the country, is largely engaged in the business of mining zinc ore as well, and the action taken in covering on a lot of high-grade ore, in open market, set operators to pondering whether or not they were receiving enough for their ore.

The lead-ore market was good but no disposition to sell freely was manifest although production was far from what might be expected under the circumstances. That a considerable tonnage of milled ore is held in bins, at various places in the field, is fairly well known. The price which held at better than \$100 per ton, 80% metal content, reached \$105 the middle of the month, and later was advanced to \$107.50 per ton in the Mo-Kan-Okla districts. It was intimated that better than this had been paid for milled lead, considered high-grade, and in one instance a seller stated that a small car had been sold at \$115 per ton. No definite price could be learned from local sources and standard publications were compelled to accept figures given out through metal exchanges. Shipments for March were extremely light when compared with reports for the preceding months of this year. Restricted milling is responsible for a lowered production, as the bulk of lead ore obtained at mills is contingent on the tonnage of mill-diet handled and fluctuates according to the volume of ore treated in wet mills. Prospecting for lead ore has been stimulated on account of the high prices, but no noteworthy discoveries have been reported.

Shipments of pyrite from separating-plants have been nil. The purchase of the Federal plant at Cuba City, adjoining the National Zinc Ore Separating Works, for the manufacture of poison gas, of a most deadly type, by the Vinegar Hill Zinc Co., affiliated with the National Separators, heralds the establishment of an important

branch of the mining industry in this field, as the plant is being made ready with a large force of carpenters, pipe-fitters, and general construction men for the making of sulphuric acid. The residue obtained at separating-plants can be utilized to good advantage in this industry and heavier deliveries of low-grade pyritic ores may be expected shortly as it is the purpose of those in control to be shipping acid by the first of next June. The gases now wasted at the National Separators in the roasting of low-grade zinc ore, or pyritic ores, will be conserved and converted into sulphuric acid.

Very little improvement was shown during March, in the output or marketing of carbonate-zinc ore, in the northern districts of the field. Some production was made at the mines of the New Jersey Zinc Co., and several new prospects have been fitted up for production, inviting a larger output during the open season in this region.

Deliveries of ore by districts, from mines to separating-plants, and direct to smelters were made for March as shown:

District	Zinc, lb.	Lead, lb.	Pyrite, lb.
Benton	9,800,000	506,000
Livingston	4,440,000
Galena	2,868,000	121,000
Hazel Green	734,000
Highland	720,000
Linden	612,000	50,000
Cuba City	166,000	206,000
Total	19,340,000	677,000	206,000

Shipments of the high-grade separator-blende, from reduction works in the field to smelters, were made as follows:

Company	Lb.
Mineral Point Zinc Co.	5,304,000
Wisconsin Zinc Co.	2,806,000
National Zinc Ore Separators Co.	2,504,000
Zinc Concentrating Co. (Cuba City)	462,000
Total	11,076,000

The gross recovery of raw ore at mills amounted to 9670 tons; net deliveries to smelters amounted to 5928 tons of blende and 360 tons of carbonate-zinc ore. On distribution the Mineral Point Zinc Co. received 3982 tons; Wisconsin Zinc Co., 2637 tons; National Separators, 2351 tons; Linden Concentrating Co., 360 tons. On high-grade to smelters, Mineral Point Zinc Co., 2652 tons; American Zinc Co., 1403 tons; United Zinc Smelters Corp., 914 tons; Grasselli Chemical Co., 571 tons; Illinois Zinc Co., 388 tons.

BRITISH COLUMBIA

PROSPECTING FOR PLATINUM NEAR GRAND FORKS.

PRINCE RUPERT.—The tunnel at the 500-ft. level at the Dolly Varden mine has struck the main orebody. The ore assays 80 oz. per ton at the point where the tunnel cut it.

The owners of the Big Missouri mine have arranged to do 12,000 ft. of boring with a diamond-drill during the present summer, and if the continuity of the orebody is

proved by this work a large concentrating plant will be erected. A quantity of machinery that is owned by the Donald Mann interests is to be moved from the Bear River district to the Big Missouri.

STEWART.—Another consignment of about 250 tons of ore has been sent to the Tacoma smelter from the Premier mine. It is expected that shipping will be carried on

nearly the whole length of the drift it is rich enough to ship. Eighteen of the 21 miles of ore is compact sulphide, mostly gray copper with a little zinc blende. It assays well in silver. Duke Harris has contracted to continue the tunnel at the Erie mine until it is under the shaft, and then to raise and make a connection

GRAND FORKS. The Provincial government has let a

THE PORTLAND CANAL DISTRICT, ON THE BORDER BETWEEN ALASKA AND BRITISH COLUMBIA

throughout the year. Machinery for the new concentrator has arrived at Stewart, and is being moved to the mine. Two engineers for the American Smelting & Refining Co. have arrived at Stewart to superintend its erection.

HAZELTON.—A drift has been run for 45 ft. on the new vein recently cut at the Silver Standard mine, near here, and the quality of the ore has greatly improved. Where the tunnel cut the vein the ore was of mill-grade, but for

contract to Mitchell & Co. for a considerable amount of diamond-drilling at Franklin, 40 miles north of here. The exploration is to be done in what is known as 'the black lead', a pyroxenite belt, which was thoroughly sampled at the surface during the War and was found to contain appreciable quantities of platinum, whether in the form of sperrylite or of native metal is not known. The first hole is to be bored between the Maple Leaf and Gloucester properties. Samples taken from the Maple

Leaf properly assayed respectively 0.15, 0.17, and 0.38 oz. per ton in platinum. The pyroxenite zone extends almost entirely across the camp of Franklin, and, together with some augite-syenite inclusions on the hanging wall forms the mineral-bearing gangue at the Maple Leaf property. Copper-bearing minerals, principally chalcopyrite, occur in bunches and veinlets through the pyroxenite and syenite and the richest platinum assays were obtained from material in association with the copper minerals. At the Mountain Lion property, however, the platinum appeared to be associated entirely with sulphides and oxides of iron.

ONTARIO

ACTIVE EXPLORATION AND DEVELOPMENT WORK IS EXPECTED AT GOWGANDA.

COBALT.—The McKinley-Darragh company is treating an average of 5000 tons of ore monthly. It is proposed to resume oil-flotation operations about the end of April, this department having been closed down in January on account of the cold weather. From the University property of the La Rose Consolidated, shipments of medium-grade ore have commenced. The development of a quantity of ore during recent months in which the average silver content is about 15 oz. per ton makes this possible. It is announced by the Crown Reserve company that the Porcupine Crown, which it controls, has entered into an agreement to merge with the Thompson-Krist company on a stock basis of two to one, the Porcupine Crown receiving 2,000,000 and the Thompson-Krist 1,000,000 shares. The Porcupine Crown retains control, and also reserves its cash from the consolidation.

The Cross Lake property has been temporarily flooded owing to the water in Cross lake having risen several feet on account of the tailing from one of the customs plants which has dammed the outlet.

Prospectors are active in the Butt township area where last year an encouraging discovery of radium-bearing ore was made. Considerable exploration work is expected to be done in that district this year.

The Cullen-Ferland-Thompson claims in Gowganda have been optioned to R. I. Henderson of Toronto for \$300,000, payable only provided ore is developed. The deal is extremely peculiar owing to it having been closed on the strength of a statement by Andrew Cullen of Haileybury that he has an instrument which enables him to discover ore deposits. The claims of the owner of the instrument are not received seriously among mining men. It is interesting to note, however, that Mr. Henderson proposes to carry out extensive exploration with it, according to report.

A discovery of silver is reported in the township of Pense, about thirty-five miles north-east from Cobalt, as a result of which a small rush has occurred and some 84 mining claims have been staked and recorded preparatory to prospecting.

The Kerr Lake has issued an interim report explaining the recent acquisition of outside properties. The company has bought a controlling interest in a Utah sil-

ver mine which has entered the productive stage, and a gold-dredging property in New Zealand, the annual income from which is estimated at about \$287,000. The company had on hand February 29 cash and Government securities to the amount of \$2,415,927.

BOSTON CREEK.—The main shaft of the Peerless has now reached a depth of 250 ft. where a station will be cut. At the 50-ft. level a drift to the west disclosed a body of rich ore which in addition to gold contained considerable bismuth. At the Kennedy-Boston mining machinery is being installed and underground work will shortly be started, involving an expenditure of at least \$10,000 in sinking and lateral work.

PORCUPINE.—The McIntyre has cut its No. 5 vein on the 1250-ft. level, at which point it is 14 ft. in width and fairly high in grade. The annual report of the Dome Lake shows an operating loss of \$94,524, the mill having been closed down since the end of June owing to a fire. During three months of operation 4433 tons of ore was treated with a total recovery of \$23,832, an extraction of 78.85%. Some changes have been made which are expected to result in increased production.

KIRKLAND LAKE.—During February the Lake Shore treated 1435 tons of ore, producing gold valued at \$40,126, being a recovery of \$27.96 per ton. The Ontario-Kirkland has made plans for the erection of a mill and will carry underground development to deeper levels to open up the downward continuations of ore-shoots occurring on the 300-ft. level. N. N. Maloof has purchased a group of six claims situated south of the Montreal-Kirkland. At the Moffatt-Hall properties comprising about 500 acres in the Lebel Township area, where several veins have been uncovered on the surface, supplies are being taken in preparatory to the beginning of work, which for some time will be confined to stripping, and prospecting with trenches and pits.

GOWGANDA.—A very active season is anticipated as development will receive a great stimulus from the bringing in of electric power and the improvement of transportation facilities. The routes for transmission lines for power from the Indian Chute generating plant on the Montreal river are being surveyed, and it is expected that several thousand horse-power will be available this year. The Northern Light Railways announce that a start will be made on the construction of its line as soon as possible. This type of railway is capable of being constructed cheaply and quickly, and will be sufficient for the requirements of the camp for some time to come. Should the extent of subsequent development warrant, it can be easily taken up and removed for pioneer work elsewhere to give place to a standard railway.

WEST SHINING TREE.—The shareholders of the Wasapika have ratified the reorganization of the company, proposed by the directors, involving the acquisition of additional territory, an increase of capitalization to \$6,000,000, and a change of name to Wasapika Consolidated. Each shareholder will receive three shares in the new company for every share of stock in the original Wasapika company.

THE MINING SUMMARY

ARIZONA

Oatman.—Cross-cutting from the 600-ft. level of the Oatman United shaft will, it is estimated, cut the vein showing on the 400-ft. level. The property is situated between the Big Jim and United and adjoins the Tom Reed.

A face of ore, seven feet wide, averaging better than \$25 per ton, is under development on the 250-ft. level of the Gold Dust. A drift is being carried west to prove the shoot and the orebody will be cross-cut at intervals of 100 ft. to prove its extent.

CALIFORNIA

Plumas County.—At the Gruss mine all efforts are being concentrated on the 400-ft. level and an order for 25 additional miners is being filled. The drift to the north has made considerable progress and the ore is widening. The south drift is proceeding in the direction of the high-grade shoot opened on the 200-ft. level at the rate of six feet per day. The cross-cut east, now out more than 95 ft., has cut another vein that pans free gold and has good copper content. This cross-cut will reach the second contact in the next 40 ft. The Gruss has now five faces of ore on the 400-ft. level, and work is adding rapidly to the mill reserve.

Redding.—A 10-stamp mill has been completed for the Juniper mine at Haydenhill. Sixteen men are employed in the mine and mill.

IDAHO

Coeur d'Alene.—Ore assaying from \$16 to \$50 per ton in lead, silver, gold, and copper has been reached in the south drift, which is being run on the 400-ft. level of the Giant Ledge mine on Prichard creek. The surveys show the vein from 60 to 91 ft. wide. The mill-frame is up, lumber is cut, and a 300-ton concentrator will be built as soon as the O.-W. R. & N. company re-builds its railroad.

Salmon.—The new volatilization plant of the Pope-Shenon Mining Co. is ready for operation, according to C. R. Bradford, secretary of the company. The crushing-plant is in condition for operation, and the smelting plant will be ready to begin work on May 1.

The crushing plant has a capacity of 200 tons per 24 hours, while the one furnace that has been erected will have a capacity of 50 tons per day. As soon as the process has been thoroughly tested, another furnace sufficient to bring the smelting capacity of the plant up to a total of 200 tons will be installed. All necessary material for this addition, except the furnace and the Cottrell treater, is upon the ground, it is said. By the Bradford process the ore is crushed to six-mesh, mixed with cheap chlorides, such as common salt at the rate of one pound of the salt to one pound of metal in the ore, and roasted at a temperature of 700° or 800°. The fumes developed from this roast are precipitated as chlorides by the Cottrell electrical separator. Crude-oil distillate is used as fuel and the collected metallic chlorides melted down to metal in a small furnace on the ground. A recovery of 85 to 90% has been made in experimental tests.

MISSOURI

Joplin.—The St. Louis Smelting & Refining Co. has completed its new mill on the Kropp land, south-west of Hocker-

ville and just south of the Santa Fe mine. The plant will be known as the Kropp mill. It was turned over for the first time about a week ago and regular production is now starting. The Kropp lease is said to be a good one and excellent results are reported from drilling operations.

The Pleasant Valley Mining Co. has been drilling at its mine on the Wyman land south-west of Carthage and has found an orebody that promises to make the mine better than it ever has been in the past. The drilling was begun to determine whether the ore was giving out or had dipped to a lower level. The drills showed that the latter was the case, but that it was better than the run on which the plant had been working. One drill-hole showed a face of ore from 128 to 148 ft. that assayed 15.25% blende, and below that to a depth of 175 ft., ore assaying 7.60% was found.

The Lucky Bill mine south of Cardin, on what formerly was known as the Cornfield lease, has become one of the steady producers of the district, making a good tonnage each week. The Lucky Bill company now is controlled by the Childress brothers of Galena, who took charge of the property last September. The mine was one of the first opened in the Oklahoma field and for some time was regarded as one of the wonders of the district. Water troubles, however, prevented full operation and it did not make the showing expected. Operations now are being conducted at about 250 ft. and at this depth the water does not interfere. One shift is being worked, both in the mine and at the mill, with a weekly production of 60 to 70 tons.

NEVADA

Eureka.—The new vein of galena ore cut in the Eureka-Holly mine last week has widened into a body of high-grade shipping ore seven feet thick, and continues to widen as development continues. Three carloads of high-grade ore were shipped from the mine to the Utah smelters last week. The circulating water tanks for the two new crude-oil engines recently erected were received this week.

Virginia City.—Alexander Wise, presumably representing the Humphrey-Wingfield interests, has acquired the exclusive right to mine the Best and Belcher, Gould and Curry, and Savage mines above the 300-ft. level by the terms of a long lease. The area embraces about 2100 ft. of the Comstock Lode, and a comprehensive sampling of the workings was made before culmination of the deal. To each company a rental of \$8000 has been paid. Development of the lower workings will continue to be done by the owning companies. It is reported in local mining circles that a mill is planned to crush the product from the leased area and other mines controlled by the syndicate. The Humphrey-Wingfield interests are actively pushing work at the Consolidated Imperial, Alpha, Exchequer, Challenge, and Confidence properties, with principal attention devoted to the Imperial. In this property extensive deposits of ore have been exposed and the outlook is good.

Ore sampling \$55 per ton is being mined in the winze recently sent down from the 1800-ft. level of the Con. Virginia. This work is opening up new territory of exceptional promise. Good ore is also under development in other parts of the property and approximately 500 tons per week is going regularly to the Mexican mill.

WASHINGTON

Keller. We expect our mill at the Iron Creek mine to be completed and ready for operation by May 15," said J. E. Anderson, manager of the property. "Ten men are at work on the property and all the equipment is across the river and on the other side of the ground. Bad roads interfered with the haul. Our compressor will be ready in two or three months. We do not need this now, for we are in soft ground. We have about 200 tons of ore on the dump ready for the mill. The mill will handle 50 to 60 tons per day, but we do not expect to run at full capacity at first."

Northport. The Gladstone Mountain Mining Co., owning a group of claims near Northport, has sent 46 tons of ore, valued at \$4039, to the Consolidated Mining & Smelting Co. at Trail. Several more carloads of ore were hauled from the mine, but not to the loading point at Boundary, the condition of the roads making progress of the trucks impossible.

Oroville. A drift on the 300-ft. level of the Kaaba mine has cut a 14-inch vein of high-grade ore that runs parallel with the larger vein on which a shaft is being sunk. The find is considered important as not only adding materially to the quantity of ore in sight, but also on account of the greatly improved grade of the ore.

MEXICO

A. J. McQuatters, president of the Alvarado Mining & Milling Co., which owns a group of mines at Parral, is quoted as saying: "Our plants have operated almost continuously since they first started in 1911, and during 1918-19 we operated without interruption of any consequence. Furthermore, there is not a smelter of any importance in Mexico that has suspended operations as a result of political conditions."

PERU

Oroya.—The Cerro de Pasco Copper Corporation has broken ground for construction of its new smelter to take the place of the old plant at La Fundicion. The plant will have twice the capacity of the old one and be able to handle a daily minimum of 2500 tons. The cost of all improvements is estimated at \$9,000,000. The building will require over 13,000 tons of structural steel and an estimated personnel of 200 to 300 Americans and a large number of native workmen. Two years is the time set for completion of the plant.

QUEBEC

Temiskaming County.—An important discovery of molybdenite in La Corne township is reported. Robert Clark, a Buffalo prospector, has located a block of claims covering 3000 acres stated to contain one of the largest deposits of molybdenite in the region.

MINERALS SEPARATION

The complaints lodged two years ago by the Federal Trade Commission against the Minerals Separation North American Corporation will soon be given a hearing. The complaints charged the Minerals Separation with stifling competition in certain phases of ore concentration; discrimination as to royalties exacted from mine operations, between favored operators and others whom they desire to "discipline," punish, and make examples of; and a number of other matters alleged to be detrimental to the mining industry. The defendants were also charged under the Clayton anti-trust act with making exclusive purchase-selling contracts, fixing prices, rebates, or discounts on condition that the purchasers should not deal in or use commodities of independent competitors. With the exception of the Jackling group of porphyries, the Butte & Superior company, the Magma Copper Co., and a few others, most of the larger mining companies have taken out licenses from the Minerals Separation company.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Rowland C. Feilding is in Canada.

C. A. Banks has returned to British Columbia.

R. A. Archibald has returned to London from Nigeria.

W. A. Noyes has been elected president of the American Chemical Society.

W. A. Howard, manager for the U. S. Smelting company at Salt Lake City, is in New York.

O. B. Smith, owing to ill health, has resigned as general superintendent for the Granby Mines.

E. Mackay Heriot has been appointed manager of the Pena copper mines, in southern Spain.

C. B. Lakenan has returned to McGill, Nevada, after spending a few days at Salt Lake City.

H. B. Tooker, traffic manager of the Jackling properties, was in Salt Lake City and Ely recently.

H. C. Goodrich, chief engineer for the Utah Copper Co., is making a business trip to Chicago and Duluth.

G. Gordon Thomas has been appointed manager for the Jos Tin Area (Nigeria), Ltd., and is now at the mine.

L. K. Armstrong and John C. Semple have formed a partnership as consulting engineers, with offices at Spokane.

John S. Stewart has become assistant smelter superintendent for the Katanga Copper Co., at Elizabethville, Belgian Congo.

Shingo Tanaka, of the Department of Finance for the Government of Japan, at Tokyo, is investigating salt industries of the United States.

Charles Janin will sail on the 'Tenyo Maru' on June 17 for the Orient. He expects to be away for five months, and will return by way of London.

Jules Labarthe, of Bradley, Bruff & Labarthe, has just returned from a three months trip to the interior of China, where he has been on professional work.

J. Benton Leggatt, president of the Argyle Silver Mining Co. in the Vipond district, Montana, has returned to Salt Lake City after an inspection trip to the property.

C. E. Nighman, formerly superintendent of hydraulic filling and fire work for the Anaconda Copper Mining Co. at Butte, has become superintendent of the company's phosphate mines at Soda Springs, Idaho.

William G. Devereux, consulting engineer for the W. C. Duncan Contracting Co., and William H. Mader, of San Francisco, are at Susanville examining the tunnel site of the Leon Bly Eagle lake irrigation project.

Gus. Scogland succeeds John Seward as manager in Salvador of the various properties of El Salvador Silver Mines Co. Mr. Scogland has been manager for the Butters Salvador mines at San Sebastian, El Salvador, for the past five years.

George E. Farish, managing director of El Salvador Silver Mines Co., left El Salvador on March 16 on a business trip to San Francisco and the West, and expects to be in New York during the month of May, returning to El Salvador in the early part of June.

William Weston, well-known mining engineer, and the discoverer of the Camp Bird mine, at Ouray, Colorado, died at his home in Denver on March 30. He was born in London 79 years ago, and came to Canada when 14 years old. He came to the United States in 1870, and became general traveling agent for the Kansas Pacific railroad. He was later associated in mining with the late David H. Moffat and was widely known throughout Colorado. He leaves his wife, a son, and a daughter.

EASTERN METAL MARKET

(By wire from New York)

April 12.—Copper is quiet and steady. Lead is quiet and steady. Tin is dull but strong.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it. Being a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, free trade in quotations. During the restricted period, the British government fixed the maximum price five times the last being on March 25, 1919 on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 lines) in British currency is 16 1/2 pence per ounce (92.5 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

The rise in sterling has been due to several factors. First, and most important, is the report from London officials that for February, 1920, the balance of trade was a credit of \$400,000,000 more than her visible exports. But invisible exports more than made up this difference. Secondly, United States imports were low in the recent past have been receiving goods from the United States are now importing goods from England. Payment for these imports created a demand for sterling bills, with the result that sterling has risen to new high levels.

Although the foreign exchange market for the past few years has been a sympathetic one to the United States, when sterling advanced so did the Continental exchanges, and vice versa. A reversal has occurred the past few weeks. Sterling advanced to new high levels for the present movement, while here at home were depressed, and other Continental exchanges declined substantially. The third factor has been the shipping of gold from London to New York. This step has been continued as an indication that England is in a strong financial position, and may, in the near future, resume her regular gold shipments.

With metal shipment of approximately \$9,000,000 British gold bars now in hand bank reserves Wall Street is speculating as to how large the movement to this center will be. The banker who gave the early information that an extensive gold movement was about to begin in connection with maturity of the Anglo-French loan says that the two shipments reported amounting to about \$20,000,000 are only a small part of what is scheduled to be shipped here during the next few months. He says gold will be coming in in payment has been sent to provide payment for the Anglo-French loan in October. It is estimated that at least \$100,000,000 will be sent here by Great Britain and that possibly as much as \$150,000,000 may be forwarded.

Britain's share of the Anglo-French obligation is \$75,000,000. This does not necessarily mean that England must ship gold here to that amount. She does not necessarily need to have some balances in America. She also holds a large amount of American securities, estimated at over \$300,000,000. In international banking circles it was said that if Britain makes substantial gold shipments here it will naturally cause uneasiness in security prices and gold shipments here will afford England an opportunity to dispose of some of her American securities at higher prices and thus build up credit to meet bond maturity in the fall. The more New York balances she can establish in this way the less gold she will have to ship.

No other word has been received as to what action France will take in regard to her share of the obligation. It is felt she too will ship gold to this port. A sympathetic influx of yellow metal from abroad is much expected to add to the credit balance of the United States. If importations of gold should be substantial this would be a great help to offering a larger amount of Treasury bills. The result of the operation of these Treasury bills is to be seen in the market. The New York office has approximately \$100,000,000 in gold in its own vaults and in the vaults of the San Francisco.

Foreign quotations on April 15 are as follows:

Sterling dollars	100	3.96
French francs	100	3.45
Italian lire	100	5.94
Spanish pesetas	100	3.90
Portuguese escudos	100	2.10

Eastern Metal Market

New York, April 7.

The markets are all only moderately active largely as a result of the Easter holidays.

Demand for copper has been heavy and prices are higher.

The tin market is quiet, especially so because of the extended Easter recess of three days in London. Prices are strong.

Demand for lead continues in excess of supply and the market, though just now quiet, is very firm.

Buying of zinc is light but prices are steady.

Antimony is dull and slightly easier.

IRON AND STEEL

Increased production, better car supply, sustained consumption both at home and abroad, and lack of evidence in actual transactions of any yielding in the prices at which independent steel companies have been selling finished steel, are the outstanding facts of the week, says "The Iron Age".

In spite of all handicaps in cars and fuel, the pig-iron output again increased in March. The total was 3,275,907 tons, or 108,900 tons per day, against 2,978,879 tons in February, or 102,720 tons per day. The March rate means 40,000,000 tons per year, whereas the record for the calendar year 1916 was 39,435,000 tons.

Against the Steel Corporation's bookings for six to eight months ahead, the independent companies have three to five months' business on their books in such lines as bars, pipe, plates, and structural material.

At the annual meeting this week of the Consolidated Steel Corporation, the export company made up of 19 important independent producers, reports showed that March shipments were the best of those of the 15 months since the company was formed. Sales were also better than in February.

COPPER

There have been published estimates in the daily press of total sales of copper in March as high as 400,000,000 lb. These figures are impossible of verification. In reply to a question, the representative of a leading producer said that the sales might have been 400,000,000 or 300,000,000 lb.—"we do not compare notes"—but it is freely stated that purchases have been tremendously heavy, both for domestic and foreign account. The leading producers have advanced their quotations to 19.25c., New York, for electrolytic for April-May delivery, with a slight premium for June, and are not inclined to quote for third quarter, for which at least as high as 19.50c. would be asked. Lake copper is also strong at 19.50c., New York, for early delivery. These prices have been established by sales, though demand just now is lighter as a result of the Easter recesses. The plan for financing foreign purchases is said to be making good progress.

TIN

Due largely to the extended Easter holidays in London, where the market was closed from Thursday to Monday, and also for a shorter period here the tin market has been, and is, quiet. Very little business has been recorded and quotations are largely nominal. Prices have been fairly high, due in part to higher values for exchange. The attitude of consumers and buyers is to purchase on all recessions in values and to remain aloof on all advances. There is a dormant inquiry which will manifest itself, it is felt, on any favorable situation. Yesterday values in London were slightly lower than the day before, spot Straits having been quoted at £355 per ton, or about the same as a week ago. The quantity of tin delivered into consumption in March was 5130 tons with the metal in stocks and landing 2848 tons. The

tin afloat is reported as 2315 tons, which, with that in stock, makes only 5163 tons evidently available for April consumption. It is pointed out that should April consumption be normal then there is likely to be a shortage of supply with premium prices for prompt or nearby delivery. This is due largely to selling tin held at below import cost which has obtained for several months. Tin imports to April 1 have been 13,650 tons against 6341 tons to April 1, 1919. Of this year's imports 10,995 tons came from the Straits.

LEAD

Quietness pervades the market but values are firm—a little firmer than last week if anything, the easing tendency, particularly at New York, having disappeared. This is owing partly to a new harbor strike but also to the disappearance of the cheap sellers and those who are cutting prices. The main feature of the situation in general continues to be a shortage of supply. It is still evident that production is not keeping pace with consumption. Quotations in the outside market are back to 8.75c., St. Louis, or 9c., New York, with those of the leading interest unchanged at 9c., St. Louis, or 9.25c., New York.

ZINC

The market has been exceedingly quiet the past week compared with the erratic conditions of previous weeks. The London market has been less of a factor; it has also been quieter. Producers here are in such a comfortable position that most of them are not interested in selling at present prices. Prime Western for second quarter is quoted at 8.60c., St. Louis, or 8.95c., New York, with one seller offering at 8.50c., St. Louis. Brass special is commanding about 1c. premium and Grade A about 1c. premium over prime Western. One prominent producer predicts 10c. zinc by the middle of the year and is very bullish on the outlook. He expects much heavier buying by galvanizers and continued consumption by England.

ANTIMONY

The market for the better grades is slightly easier but quiet. Wholesale lots for early delivery are quoted at 11.37½ to 11.50c., New York, duty paid. Other grades are quoted at 10.50c., New York.

ALUMINUM

Quotations continue unchanged at 33c. per lb., New York, from the leading maker and at 31c. from outside interests for wholesale lots for early delivery.

ORES

Tungsten: There is a growing feeling that the tariff bill will be passed and as a result prices are firmer and inquiry is better. The minimum in low-grade ores seems to be around \$6.50 per unit.

Ferro-tungsten is quoted at 85c. to \$1.15 per lb. of contained tungsten.

Molybdenum: Quotations are nominally unchanged at 75c. per lb. of MoS₃ in regular concentrates in a dull market.

Manganese: Foreign ore for early delivery has sold at 80c. per unit, seaboard, and demand is good from one or two interests who contemplate making ferro-manganese.

Manganese-Iron Alloys: Domestic electric ferro-manganese has sold for spot delivery at \$250, delivered, and a small amount of British alloy also. Quotations for the last half remain at \$200, delivered, for American alloy. Only a limited amount of British alloy is available for delivery from August on, at \$195, seaboard. The market is strong but not active. A sale of 250 tons for export to Canada at \$250, furnace, is of decided interest as showing the scarcity of British alloy. Spiegel Eisen is firm at \$62, furnace.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A MODERN ELECTRICAL PRECIPITATION PLANT FOR SILVER-REFINERY FUMES

The electrical system of precipitating fine particles is now used to collect smoke, fume, and dust in a variety of industries, but it is especially useful in connection with metal-refineries because of the high value of the materials recovered. A plant has recently been built in the silver refinery of the U. S. Metals Refining Co., at Chrome, N. J., which is

Fig. 1. Electrical Precipitation Plant

of special interest because it is both a successful commercial plant, and an advanced development of precipitating apparatus. Plants of this type present many engineering difficulties, for not only must practically all of the fume be recovered, since every particle escaping represents a loss, but the material precipitated in the tubes is particularly troublesome. This substance is not a fine, dry, easily-handled dust, as is the case with cement-kiln fume, for example, but a semi-liquid sludge, that is hard to remove, and is especially liable to build up on the electrodes and cause grounds. It also contains a considerable proportion of selenium compounds, which not only attack iron and steel, but ordinary commercial lead also, and only lead free from antimony can withstand selenium-carrying gases. Hence, every part of the equipment with which the fumes come in contact must be covered with chemically pure lead.

The nature of this process is generally known; it consists of passing the dust and fume-laden gases through long pipes; in the centre of each pipe is suspended an electrode charged with uni-directional current of a very high potential (in this case, 65,000 volts). The solid and liquid particles

become electrified in passing through the strong electrostatic field and are attracted to the walls of the pipes, which are grounded. The plant is shown in Fig. 1.

The treater itself is supported on a structural steel framework and consists of three units of 30 lead-lined tubes each. The electrodes contained in the tubes are rigidly suspended from the top so that bottom insulators can be dispensed with.

The gases from the furnaces are first passed through scrubbers and sprayers, which remove a portion of the fumes and cool and moisten the gases to the proper degree. They then pass into the top of a large header, into which the precipitating tubes project several feet, so that irregularities in the gas-flow are prevented. The pipes are heated to the same temperature, and a uniform flow is established through each pipe. After passing through the pipes, the gases, now free from fume, escape into the atmosphere. As soon as the maximum permissible amount of precipitate is collected in the pipes of any unit, the gas flow and the electric current to that unit are cut off, and the precipitate is flushed out of the pipes by a washing system.

The electrical equipment which produces the high-voltage direct current is shown in Fig. 2. There are two units, one for regular operation and one as a spare, each consisting of a motor-generator set, a high-voltage transformer, and a

Fig. 2. Motor-Generator Sets and Rectifiers

mechanical rectifier. The motor-generator set is made up of a 40-hp. 220-volt Westinghouse direct-current motor, and a 25-kva., 220-volt, 60-cycle Westinghouse alternating-current generator. The motor is driven from the power-circuit of the plant and the generator supplies the current for the precipitation system.

The low-voltage current from the generator goes to the transformer, which is of a special design made by the Westinghouse company. It is of 25-kva. capacity; takes low-voltage current at 220 volts, and has taps in the low-tension winding for transforming the current to 55,000, 65,000, 70,000, and 75,000 volts respectively. Its high voltage ter-

minals are of the well known condenser type to protect the transformer-windings against grounds caused by high over-voltage surges during operation. After the low-voltage alternating current has been transformed to high-voltage it goes to the mechanical rectifier which is a simple form of commutator and is kept in synchronism with the current by being mounted on the generator-shaft, changing the high-voltage alternating current into uni-directional current of slightly lower voltage. The high voltage uni-directional current then goes to the treater.

One of the difficulties that must be overcome in this system is the occurrence of high-voltage surges, which originate in the treaters and, if not damped-out, will pass on through all the apparatus in the circuit. To prevent this, carborundum resistance-rods are connected in series with the high-voltage D.C. circuits, and the transformers are protected by means of choke coils mounted within the cases. As the treater circuit is electrically distinct from the power-circuit of the plant, these surges cannot pass back into the latter circuit.

For the convenience of subscribers and others requiring technical books the Book Department of 'Mining and Scientific Press' has prepared a 72-page catalogue of books carried in stock at San Francisco. A copy will be mailed upon request to those interested. A summary of the contents of each book is given and in addition to an index by authors the following grouping according to subjects is made: Assaying, Chemistry, Civil Engineering, Concrete Construction, Cyanidation, Electrical Engineering, Electro-Chemistry, Engines, Geology, Hydraulics, Iron and Steel, Irrigation, Law, Machine Shop and Foundry, Mathematics, Mechanical Drawing, Metallurgy, Mineralogy, Mining Practice, Miscellaneous, Miscellaneous Engineering, Ore Deposits, Ore Dressing, Petroleum, Placer Mining, Prospecting, Scientific Management, Smelting, Structural Engineering, Surveying, and Water Power.

COMMERCIAL PARAGRAPHS

The manufacturing sales-department of the **Wellman-Seaver-Morgan Co.**, which handles the company's sales of rubber equipment and machinery, and which is in charge of L. N. Ridenour, moved on March 31, from the company's Akron office to its general offices at 7000 Central Ave., Cleveland.

D. Gleisen, manager of the industrial bearings division, **Hyatt Roller Bearing Co.**, announces that his office has been moved to a new building at 100 West 41st St., where much larger quarters have been secured for the advertising, sales, and engineering departments of the division. The new building is conveniently situated and customers are cordially invited to use these offices as their headquarters whenever they are in New York.

'Power Transmission in Principle and Practice' is the title of a neat new publication from the **Main Belting Co.**, manufacturer of Leviathan and Anaconda belts. It presents in concise form the standard formulas and data developed by leading transmission engineers for the selection and use of belts. The service required of a belt determines what kind, grade, ply, and size of belt should be selected. The pamphlet supplies this information in a convenient way.

Charles C. Phelps recently became associated with the **Fehling Instrument Co.**, 71 Broadway, New York, combustion engineers and manufacturers of fuel-economy apparatus. He is devoting most of his attention to research work in connection with the efficient combustion of fuel-oil in boiler-furnaces. It is estimated that nearly \$100,000,000 is wasted unnecessarily every year, due to improper methods of burning fuel-oil, which fact shows the importance of this field of investigation. Mr. Phelps graduated from Stevens

institute of Technology with the degree of mechanical engineer and has since spent several years studying power-plant problems. Mr. Phelps is an associate member of the American Society of Mechanical Engineers.

The **Denver Quartz Mill & Crusher Co.**, of Denver, has received the following orders: from the Bolivian Mines Co., La Paz, Bolivia, two No. 2 Denver quartz-mills, two No. 2 Denver ore-feeders, and one 8 by 12-in. Denver steel-crusher; from Teats & Co., Paramaribo, Dutch Guiana (second repeat order), one No. 2 Denver quartz-mill and one No. 2 Denver ore-feeder; from M. McCormick Co., Stockton, California (repeat order), one No. 2 Denver quartz-mill and one No. 2 Denver ore-feeder.

'Little David' pneumatic drills, grinders, and saws are described in a recent catalogue issued by the **Ingersoll-Rand Co.** The company claims that the 'Little David' drill will do more work per unit of power and will take a greater load without stalling than any other drill built for equal duty; that it has at least one-third fewer parts than any other similar drill; and that it requires less attention and costs less to repair than any other drill. It can be disassembled in one-third of the time required by any other make.

To meet the rapidly growing demands of its business the **A. H. Simpson Co.** is enlarging its machine-shop, installing about \$10,000 worth of new apparatus, and greatly increasing its facilities to ensure immediate delivery of re-built equipment. The new installations, which include a \$4800 lathe and a \$3000 miller, will permit the handling of much heavier work than could have been taken care of in the past. A part of the new equipment will be largely devoted to the manufacture of a new carburetor for use with a low-grade fuel. This carburetor has been in use under various severe tests and conditions and, according to the manufacturers, has satisfactorily demonstrated a marked superiority over present devices for carburetion of low-grade fuels.

A new grain elevator recently finished near Baltimore has a capacity of 4,257,000 bushels, whereas the other seven elevators now in use there have a total capacity of only 10,000,000 bushels. The grain storage capacity at the railroad terminals therefore will be increased nearly 43%. This monster grain elevator is equipped throughout with elevator and conveyor-beltting made by the **B. F. Goodrich Rubber Co.** This represents the largest single order of beltting ever shipped and it required seven box-cars to transport it from Akron to Baltimore. The beltting totaled 44,254 ft.—approximately 8½ miles—and weighed 131 tons. The capacity of one of the 48-in. horizontal carrier belts is 350,000 bushels in a ten-hour day. Accommodations are provided for the loading of five ocean liners at once, and with the new apparatus for loading that has been installed, the ships can be loaded within 20 hours.

The **Flexible Steel Lacing Co.** points out some of the reasons why steel belt-lacing is recommended instead of the older kinds. Probably the most important is the feature of time saving. While cemented belt-ends have great strength, the requirement of time and the services of an expert to make repairs have stopped the use of cemented belts wherever they can be done away with. Leather lacing is still in general use, but is constantly losing favor because of the difficulty and delays in making the joint and because of the low proportion of strength which the lacing gives as compared with that of the belt. Alligator steel belt-lacing has the advantages of (1) time saving—the delay caused by a broken belt is practically negligible; (2) strength—the strength of Alligator lacing averages 60% of the breaking-strain of the belt while the average working-strain on a belt does not exceed 20%; (3) high efficiency—permits use of either face of belt in contact with pulley, gives the greatest arc of contact with pulley, is thoroughly adaptable to use on all belts and pulleys of both large and small diameter.

T. A. RICKARD, . . . Editor

THE Modern Language Association of America has withdrawn its approval of simplified spelling and abandoned the use of it in its own publications. For eleven years the Association has endeavored to reform spelling on the basis of 'simplified' propaganda. We congratulate the Association on its good sense.

RECENT insurgent strikes among the railroad-workers have shown how undisciplined are the ranks of labor. Apparently a radical group made an attempt to disrupt the railroad brotherhoods and the American Federation of Labor. The Attorney General is quoted as having said that he has evidence to prove that the walk-out was "designed to capture American industry, overthrow the Government, and set up a dictatorship like that of Russia". This is a strong statement and we hope that Mr. A. Mitchell Palmer will not delay in giving publicity to his proof of it. The capture of a courier from Lenin to the agitators responsible for the strike is another sensational item that should be either proved or disproved. Loose assertions in such serious matters are much to be deprecated especially if made by Government officials. Apparently the attempt was a blow at unionism as well as industry; it was not preceded by any demands, and no leaders were identifiable; it was a stab in the dark, an act of social sabotage such as we have learned to associate with the enemies of orderly progress in Russia and elsewhere. It is fortunate that the recognized leaders of labor were able to assert their authority and that the force of public opinion killed the revolutionary movement so quickly. We must recognize once and for all that the general strike is tantamount to a revolution; it is a revolt against government in any form; it is the suicide of democratic institutions.

INNATE optimism nourishes the belief that certain silly notions about mining have been outgrown. The doubtful cynic need go no farther than Tule canyon, near Goldfield, to find tangible and ample evidence to the contrary. There he will find a recently finished stamp-mill, completely equipped for operation, with a 24,000-gallon water-tank conveniently situated on the near-by hillside. He will observe also a neat head-frame and hoist, and a dump of excellent rhyolite, which has come from an entirely respectable 60-foot shaft which is as plumb and true as any that ever was sunk. Everything

appears to be in readiness to start hoisting ore. In imagination he hears the stamps falling; he sees the battery-man dressing the plates, and finally he pictures the proud superintendent admiring a big bar of shining yellow gold! Gold? We all know the idea cherished by many old-time prospectors that a particular brand of nature's gold has the amazing faculty of eluding the assayer in some mysterious manner, although its presence in gravel or quartz can readily be 'proved' by the simple manipulation of an ordinary iron pan. Many an assayer has been branded as a fool or a crook because he reported a 'trace' in an 'ore' that had strung the old digger's pan half-way 'round. That is the kind of gold they have at this mine in Tule canyon, and the remarkable part is that after assays actually had been reported as blanks the original owners persisted in backing the evidence of their panning. But that is not all. They needed capital and they finally interested some people who thought it would be romantic to own a mine. These backers fell directly into another blunder which we thought was a memory of a forgotten past. They saw a wonderful opportunity for 'economy'. Why pay a high-priced engineer for looking into so simple a thing as a gold mine? There was the gold, one could see it in the rock! They 'saved' a \$500 fee—and sunk 15 or 20 thousand dollars where they will never get it back. Yes, and another is being born every minute.

ALASKA is a subject that interests most of our readers. We are glad therefore to give space in this issue to an article on 'The Future of Interior Alaska' by that veteran geologist, Mr. R. H. Stretch, whose book on 'Prospecting' has made his name honorably known throughout the West. The physiography and economics of the great mining territory in the north-western corner of this continent are too little understood, even by those engaged in the exploitation of mineral deposits. Mr. Stretch presents the salient facts in a clear and informing manner. We are glad to know that the mismanagement, verging at times on misrule, from which Alaska has suffered, owing to the confusion created by conflict of authority between various Federal bureaus, is shortly to be remedied by submitting Alaskan affairs to a central advisory body. As an example of the annoying and absurd division of authority we may mention that the brown, or Kadiak, bear is under the protection of the

Department of Commerce while the other bears are within the domain of the Department of Agriculture. Mr. Stretch makes a plea for the prospector and suggests the preparation of a map especially suited to his needs. One must acknowledge, however, that the U. S. Geological Survey, more particularly the Alaskan division under Mr. Alfred H. Brooks, has done yeoman service to this mineral region. If therefore any new map is needed or desired by those engaged seriously in exploration or development, we feel sure that it will be provided in due course. No mining territory, it is safe to say, has ever received such persistently valuable scientific assistance as Alaska has received from the Geological Survey. If the other departments of the Government had supplemented that assistance by a properly co-ordinated scheme of administration, Alaska would be in a much better position than it is now. We look forward to an improvement in that direction.

IN this issue we publish the first of a series of articles by Mr. Walter S. Weeks, Associate Professor of Mining in the University of California, on the important subject of ventilation in metal mines. This is a phase of mine operation that has only recently been given proper consideration: it deserves earnest study and we are glad therefore to note that those specializing in this branch of mining engineering are winning an important place in the organization of metal mines. Work in a vitiated atmosphere has been responsible largely for the prevalence of sickness and for the premature breaking down of miners; the necessity for the conservation of manpower and humanitarian considerations alike dictate an effort to maintain good air underground. But there is another and more immediate angle to the problem which is being more fully recognized as a result of intelligent study, namely, the increased daily accomplishment of the miner who is working in a reasonably pure atmosphere and the consequent reduction in the cost of mining. In several mines the introduction of an adequate ventilating system has been given credit for raising the efficiency of operation as indicated by the tons-per-man output by as much as 100%. Other things may have entered into this improvement, but the introduction of suitable ventilating equipment is given as the major factor. It is not always essential to use large and expensive blowers, although a few small mechanical units are generally necessary in order to reach isolated points. Quite frequently fresh air naturally enters the workings through down-cast shafts in sufficient quantity to maintain a satisfactory condition throughout the mine if it be properly distributed. We have known mines where miniature hurricanes raced through the principal connections between the down-cast and up-cast shafts, but where the air in many of the stopes was decidedly poor. The same condition may exist where a large central blower-station draws a good supply of new air into the mine. The problem of getting fresh air into the stopes is complicated by the intricacy of the passages. The position of bulkheads and doors and the adjustment of regulators can only be determined after

careful study; in new work subsequent difficulty can be avoided by driving cross-cuts and raises in accord with the future requirements of a systematized plan of ventilation. The principles of mechanics and physics underlying problems in ventilation are not complicated, but the available data derived from the practical application of these principles are meagre. The present excellent articles are the work of a technician familiar alike with scientific principles and the application of them underground; they will be made more valuable if they form the basis of discussion and elicit information from those in charge of mines, as well as from consulting engineers.

The Revolt of Sonora

Interest in Mexican affairs has been revived by another revolutionary outbreak. Something of the kind was to be expected, of course, because it is customary on the eve of a presidential campaign in Mexico for the candidate opposed to the party in power to protest, usually not without reason, that the purpose of the ballot is being defeated by corrupt proceedings, commonly a tyrannical interference with the process of election. The latest insurrection against Carranza's regime takes the form of a secession of the State of Sonora, under the leadership of General P. Elias Calles. Not content to declare the independence of Sonora, this *revoltoso* has already invaded the neighboring State of Sinaloa and appears bent upon breaking Carranza's rule in northern Mexico. Several States are said to have joined Sonora, and sundry detachments of Carranzista troops have gone over to the rebels. This outbreak, it is reported, has been organized in support of the candidacy, to the presidency, of General Alvaro Obregon, who is expected shortly to assume the direction of the military campaign against Carranza. This, of course, is an old story; some such revolt was anticipated; but it has an interesting phase, because it suggests another Texas. It appears possible that a group of northern States, say, Sonora, Sinaloa, Chihuahua, and Coahuila, may secede from Mexico and form a separate republic, under the friendly protection of the United States. Later either another revolution or an attack from southern Mexico might lead to annexation or absorption of northern Mexico into the American Union. We are not informed concerning the foreign interests that may be supporting General Calles, but inherently it is probable that American mining operators and others on this side of the Rio Grande are giving assistance to the development of a situation likely to bring about conditions favorable to orderly government and the peaceful industry dependent upon such government. Certainly we sympathize heartily with the representatives of Arizona, Senator Ashurst and Governor Campbell, in their protest against allowing Carranza's troops to cross into American territory for the purpose of expediting an attack upon the Calles forces in Sonora. Carranza and his government have forfeited any claim to friendly consideration at this juncture, nor is it in the least desirable, or even endurable, that Mexican troops

should conduct any part of their operations on our soil. To the mining public it would be satisfactory if the northern States, constituting a mineral region of prime importance, were to be separated from the rest of Mexico and placed under a stable government of any kind. In these matters, however, we do not forget that the welfare of the mining business, even the interests of our own readers, must be subordinated to the wellbeing of the United States as a nation. We look askance at any steps that may involve the addition of a large Indian stock to the unassimilated elements that retard the Americanization of our existing population. The inhabitants of northern Mexico are 80% Indian and 80% illiterate; it is to be hoped that before they are driven by the logic of events under the American flag they will have been prepared in some measure for citizenship. Mexico needs an army of Boston schoolma'ams more than an incursion of doughboys. The establishment of a northern republic between the Rio Grande and the rest of Mexico would serve as an intermediary process for benevolent assimilation. The task of true statesmanship is not to expedite, but to delay, the extension of American domain southward and to do it by giving sincere assistance to our neighbors, so that they may educate themselves slowly to a condition rendering possible some form of government better than that of military dictatorship, which, as yet, seems to be the only one applicable to an illiterate people.

Geologists in the Courts

During December and January we referred to apex suits and to the participation of geologists as expert witnesses. This was apropos of the suit then being heard at Salt Lake City, but it referred to a system rather than to an incident. Unfortunately we used a phrase, and we used it twice inadvertently, that has offended several real friends among the scientific men that took part in the Bingham suit. The offending phrase made reference to six good men on one side testifying that something was black while six other good men swore that it was white, that is, that the evidence of honorable geologists was not infrequently so contradictory as to discredit the science of geology and the whole system of juridical procedure, in apex suits more particularly. This criticism was not liked by some of the geologists, and the apposite phrase itself was taken in a sense never intended. It was taken as a personal attack, and it should not have been. We might mention names just to emphasize the absurdity of any charge of a lack of integrity on the part of men for whom we have the highest personal regard, but it would be impertinent. The fact is that nobody likes to be criticized even indirectly and not many remember when their actions are discussed, even as the innocent part of an objectionable system, that the editor's function is to criticize. Literature is a criticism of life; technical literature is a criticism of the life and doings of technicians. We were attacking a vicious custom, one to which the geologist is related as its victim as well as its beneficiary; we hoped by criticism to help in provoking

the demand for a change, in order to criticize we had to run the risk of annoying some good friends. We took that risk, which is the greatest risk an editor incurs. The dozen men we had in mind are professors and practitioners in the front rank of the profession; they are in the grip of a system the defects of which they will be the first to acknowledge. Those engaged in operating mines are becoming sensitive to the absurdity of current procedure in the courts; many of them have written to us urging us to ventilate the matter. To do it effectively we shall need the aid of the geologists themselves. One of them, Mr. Augustus Locke, has acknowledged that there are two kinds of geology, that which concerns itself with the search for ore and that which is devoted to the confusion of the law of the apex. Here we may say that the suggestion has been made that our interest in the matter has been prompted by a noted authority on mining law, whom indeed we can specify as the most authoritative writer on the subject. The suggestion is entirely erroneous; it is as erroneous as it can be. That must suffice. Several mining engineers have discussed the question with us, for it is becoming recognized that much the same group of experts appear in successive cases and that the failure of mining companies to avail themselves as much as they might of the advice of consulting geologists is due in part to the spectacle of conflicting views as aired in the courtroom. Further, the prejudices engendered by partisanship in these apex suits entails a loss to geology in so far as they involve any departure, however unintentional, from intellectual honesty. Can one be partisan and yet intellectually honest in the scientific sense? Can one be a 'good' witness without being partisan? We could not. Lawyers tell us that witnesses usually espouse the cause of the side that calls them. It is human to take sides, even when watching a game, much more when taking part in a contest.

Is it not practicable to devise a method by which witnesses will not be pushed into the attitude of advocates? We think there is, provided those concerned are sincere in their efforts to find an escape from current practice in the courts. Would it not be possible for the two litigants to agree, with the concurrence of the judge, to try their case with the aid of one geologist on each side and a third geologist to be selected by the other two, this third geologist to be attached to neither side, but to aid the judge in clarifying the testimony in so far as it relates to the facts in the case? Or make it two on each side, with a fifth to serve as a detached expert. The geologist thus selected would be chosen for his intellectual honesty, a quality infinitely rarer than commercial honesty and rare even among the best of men; he would be in a position offering no temptation to be otherwise. The procedure would require no act of legislation; it could be adopted by consent of the parties at issue, if the judge concurred, as probably he would, because it would facilitate his purpose, which is to arrive at the truth. It were better to allow the selection to be made by the other geologists than by the judge, because they would be better able to make a good selection. If left to the judge, he would have to

seek advice from among his acquaintances, and thus pass the responsibility to some casual person, probably not without prejudice, personal or otherwise. After all, what is needed is the ascertainment of fact—that is, of such facts as are determinable—for a juridical decision. Usually the harassed judge is asked to deliver a legal opinion on a maze of contradictory statements, dealing with the highly technical phases of a subject with which he is unfamiliar. More than once the court has expressed surprise and chagrin at the contradictions involved in expert testimony from opposing litigants, and acknowledged the difficulty of reaching the right decision upon such an insecure basis. We are confident that mine operators and consulting geologists will find the courts not unwilling to give a favorable hearing to the suggestion of any method that will expedite their work and facilitate their function. One thing is sure, the descriptions and explanations of such a court geologist, that is, of one selected to be non-partisan, would at once become valuable technically; they would form the basis for a reference library of mining geology, in a manner quite impossible so long as men of the highest character are marked as partisans from the start by the fact that they appear in court to support one side of a controversy. We commend the subject to the attention of our readers, especially those most concerned, and we hope to receive a statement of their views for publication.

Complex Ores in California

The recent closing-down of the Afterthought mine, in Shasta county, again calls attention to the fact that scattered along the Sierra Nevada in California are large and small deposits of complex sulphides that are not being exploited. These ores carry gold, silver, zinc, copper, lead, iron, manganese, calcium, barium, and other elements in subordinate amounts, the precious metals in some instances being present in quantities sufficient to be attractive even when considered apart from their base associates. Inasmuch as none of these properties are being operated at the present time, although some of them are equipped with extensive plants of expensive machinery, it can be assumed that the metallurgical methods used did not produce satisfactory commercial results, particularly as ample capital was provided for all requirements. If this deduction is correct the question then arises: Wherein have the metallurgical processes adopted been at fault? Taking the Afterthought mine as a typical example of these Californian complex sulphide deposits, reference to the files of the 'Mining and Scientific Press' shows that a number of methods of treatment have been tried at intervals, and as each effort resulted in a shut-down, it can only be assumed that conditions at the property were not met successfully. The presence of a large amount of zinc in the ore interfered with the recovery in two ways; (1) it made smelting difficult, if not impossible when the output of the mine as a whole is considered; and (2) the value of the contained zinc was proportionately too great to permit the

ore being treated for the other metallic contents alone. The zinc in these ores must be put in a form in which it will contribute to the economic result and cannot be thrown into the discard. In addition to its separation from the associated metals, it must itself become an asset, and not a liability, if mineral deposits of this character are to be profitably exploited. It will be noted, in reviewing published accounts of metallurgical operations on complex sulphide ore in California where zinc is a prominent feature, that in almost all cases a concentrate was produced that had to be shipped to some distant point for further treatment, or else an attempt was made to convert the metal into spelter. In only a few instances, in this State have the salts of zinc, such as zinc oxide, zinc sulphide, and zinc chloride, been manufactured. In California there is a comparatively light demand for spelter, but, on the other hand, the oxide is used in large quantities, as is also the chloride, and the outlook for zinc sulphide as an important ingredient of 'rubber' tires is promising. Zinc oxide is brought from New Jersey or Kentucky. The problem of the complex zinc sulphides will be solved sooner or later, and, in view of what already has been done in this direction, the proper mode of procedure would seem to be to convert the metal from ore into salts of zinc which command a higher price per pound of contained metal than is paid for it as spelter. In the case of the Afterthought, determined efforts have been made to discover some means of utilizing the large body of complex sulphides locally available. Evidently, from published accounts of what has been done recently, flotation methods were not successful. Flotation simply produced a concentrate that found its nearest market in Oklahoma. We presume that the management, before closing down, carefully considered all means of keeping the plant in operation, if for no other reason than to avoid such rapid deterioration as inevitably overtakes an idle metallurgical establishment; but we have not seen in any account of the operations to what extent zinc can be removed from the 'collective' concentrate by giving it a sulphatizing roast followed by leaching with acidified water derived from passing the roaster-fume through suitable towers. Once a portion of the zinc is obtained in soluble form, it can be thrown down as any desired salt by chemical precipitation, and, if not the whole, at least enough of the metal can be recovered in this way to release the associated metals for furnace treatment. Objections to the sulphatizing roast, if set forth under 'Discussion', might elicit other suggestions on the part of our metallurgists which would assist in solving the difficulty. As it is a function of a publication devoted to mining and scientific matters to lend what aid it can to the furtherance of the interests it represents, a frank and free discussion of the causes that have led up to the shut-down of the Afterthought, and similar properties, cannot but be beneficial to all concerned. The idleness of these mines is a serious detriment to the mining industry on the Pacific coast, and we believe a remedy can be found if the cause is purely metallurgical. We invite discussion.

The Future of Interior Alaska

By R. H. STRETCH

INTRODUCTION. Since the first day in which the Territory of Alaska was recognized as a valuable asset of the United States, it has been the custom to speak of it as a unit. As a matter of fact there are three Alaskan territories differing so radically in topography, climate, resources, and social conditions that no general description will convey a true conception of any one of them. The Alaska Bureau of the Seattle Chamber of Commerce has done magnificent work in dissipating the old erroneous conception of a worthless frozen land of ice and snow, stupendous glaciers, and terrific blizzards, but it has not dwelt on the essential differences between the coastal region and the interior. The purpose of this article is to supply the deficiency. The vast majority of tourists see but one side of the picture, and but little of the economic questions that bear so heavily on the other.

COASTAL ALASKA embraces all the region from Ketchikan in the extreme south-west to Unimak island in the extreme south-east, a distance of 1500 miles, and extends inland to the summit of the Alaskan range. It is essentially a mountainous area, with varied resources; immense fishing industries, valuable mines of coal, oil, gold, copper, lead, zinc, marble, gypsum, and barite; extensive forests and potential wood-pulp enterprises, with considerable areas of agricultural land in the Chilkat, Copper River, and Suisitna valleys, as well as many spots suitable for truck-farming among the islands of the Alexander archipelago; but it is not primarily a farming region.

ARCTIC ALASKA lies north of the Endicott mountains, and all its streams flow into the Arctic ocean. Although known to possess coal, asphalt, oil, and more or less gold and copper, its present commercial resources are furs and whales, which have no bearing on this discussion.

INTERIOR ALASKA is co-extensive with the entire basin of the Yukon river and its tributaries, from the Endicott mountains to the Alaskan range, and from the Canadian boundary to Bering Sea, into which the river system empties. Aside from furs, its exports to date have been chiefly gold, with small amounts of tin, antimony, and tungsten. There are enormous deposits of lignite, but no known deposits of iron, neither are there forests of commercial timber so that the outlook for manufacturing industries is not promising. It has, however, wide areas that have been proved capable of growing most of the products of the temperate zone, including the hardier cereals. These conditions point to the development of its farming resources as the road to prosperity. While Coastal Alaska has a heavy rainfall and a moderate range of temperature, Interior Alaska has only a light rainfall, with long cold winters and hot summers, or, in other words, a climate of the continental type. Its ocean front-

age on Bering Sea and its entire river system are frozen for at least half the year and communication with the outside world in winter has been possible only through three passes (practically one) in the southern mountain barrier; by dog-team in the olden time, by horses at a later date, supplemented today by automobiles. Importation of heavy goods in winter has been impossible and mail-service has been cut down to letters and a very limited amount of printed matter. Daily communication is maintained by telegraph and wireless.

AREA. The total area of Alaska is a trifle less than 600,000 square miles, equal to one-fifth the total area of all the other States combined, twelve times the size of the State of New York, or ten times the area of England! Leaving out the islands it is a compact body of land roughly 700 by 800 miles. The portion occupied by the Yukon Valley or Interior region is probably about one-third the whole.

POPULATION. On account of the migratory character of the population, due to the rise and fall of mining centres, it is difficult to arrive at an accurate estimate of its numbers. An analysis of the so-called white population (usually given as 45,000 to 50,000 in a normal year before the War) indicates a population of from 12,000 to 15,000 persons in the Yukon Valley and Arctic Alaska. It is not easy to say how many of these should be assigned to Nome and the rest of the Arctic zone, but it seems safe to say that not more than 12,000 were settled in the Yukon Valley. This means one person per 17 square miles. Since the War the population has been depleted, so that there is small chance of this sparsity being exaggerated. The census will give no idea of the summer population, because every miner who could do so has apparently gone south for the winter and will be counted in some other community.

This handful of people, it is scarcely correct to call it a community, is isolated from the rest of the world by a wilderness, so that its only contact with the outside world is by ocean and river steamers and the 110 miles of the White Pass & Yukon Railway. Every link in these lines of transportation is handicapped by physical and social conditions unfavorable to an economical service. Nowhere is it possible to get the full measure of efficiency from any of the costly equipments. Especially is this the case in the Yukon Valley, where the boats are idle more than half the year, with a long list of fixed overhead charges to be borne by a traffic that is one-way only, as far as freight is concerned. Omitting gold, Alaskan exports for October 1919 exceeded \$19,000,000, but not one dollar of this came from the Yukon Valley!

No distributing industry can be run to the full capacity of the plant under such conditions, when its life de-

pends on the patronage of the public; high prices for the service must inevitably result. The newspaper can just as well run off thousands of copies instead of an edition of a few hundred; the cook in the restaurant is never busy to his full capacity; the movies can as easily serve audiences many times larger, and the light and telephone system a much greater clientele, while every merchant is expected to keep a good assortment on his shelves in spite of his small daily turnover. These are conditions incident to all small communities far from large centres of population and are not peculiar to Alaska, but perhaps they are felt there more acutely because the population is largely made up of miners who demand the best of everything. This is reflected in the fact that until quite recently the smallest coin in circulation was the 25-cent or 'two-bit' piece. The use of lesser denominations was looked upon as the end of the good old times, a sign of decay! It seems likely that while natural obstacles may have affected freight-rates, the difficulties attending the distribution of the freight and the necessities as well as the luxuries of life to the ultimate consumers, so few and so widely scattered, may be the dominant cause of the high cost of living, that is simply intensified in the interior.

We call these Alaskans 'pioneers', and in the sense that they are on our last frontier they are entitled to the honorable name, but the present generation is in no other sense comparable with the men who pushed westward into the great unknown a hundred years ago. Those were building homes for themselves and their descendants—the Alaskan pioneers have been more like Kipling's 'Gentlemen Rovers', leaving expensive tin-cans along the trails instead of their homes. The present race wants good clothes instead of homespun and buckskin; they have tasted the luxuries of civilization and must have the fruits of the tropics as well as the produce of their own acres; electric lights instead of a home-made tallow candle; the daily newspaper instead of the gossip of a chance wayfarer; automobiles instead of an ox team; the whole gamut, in fact, of modern inventions and appliances in place of the humdrum life of their prototypes unrelieved by anything more exciting than a house-raising bee for a new settler. Those men were content to be out of the world and by the world forgotten; their successors in the north must have a digest of the happenings of the entire world on their breakfast table, or feel that they have been cheated out of their just rights; and what is more, they want these things at a much lower price than they are now paying for them. Unfortunately there seems but small hope of their wishes being realized for years to come. Few of these men went to Alaska with the intention of becoming attached to the soil. Like all the rest of their fellows they sought a competence where apparently it was to be found as promptly as possible, and it is nothing to their discredit that when successful they should select a home for their mature or declining years on the 'outside'. They cannot be called quitters for they never intended to stay, neither can they be expected to stay when they can so easily become part and parcel of

the surging humanity of more crowded centres and more genial climes. When in Alaska they naturally drop into four classes or groups: miners, farmers, merchant distributors, and operators of public utilities. The last three at this writing are entirely dependent on the first; when mining is prosperous all share in the prosperity; when the mining population decreases there are fewer mouths to be fed from the surplus products of the farms; there is a lessened demand for clothing and imported articles, and less money to spend on telegraphs, telephones, light and water service, newspapers, and theatrical amusements. When any purely mining camp is dead all dependent life dies with it.

The building of the Government railroad from Seward to Fairbanks, while projected as a business enterprise to open up the coal deposits, was undoubtedly underlain by an altruistic idea that easy flight from the long winter nights might stem the tide of annual migration on the theory that when you find that you can easily do what you wish to do, the desire to do it fades away. It is too early to say what the result may be in holding the present population of the interior or of increasing the same, but it may be profitable to see if it is likely to accomplish this result in any appreciable degree by reducing the cost of living and operating.

Three definite ideas underlaid the scheme. First, the opening of the Matanuska coal-field; second, the opening of the Susitna valley; third, the relief of the interior by building a railroad from Broad Pass to Fairbanks, a distance of about 150 miles. As the road is less than 500 miles long, and is costing \$52,000,000, it is not unfair to assign \$15,000,000 as the sum to be accounted for by the Interior Zone, or Yukon Valley. Interest on this sum at the rate of 5% and depreciation at the same rate, together with yearly maintenance and operating costs, to say nothing about interest on the millions lying idle during the period of construction, will easily range somewhere between one and a half to two million dollars, while the imports to the interior, as shown by the Custom House returns for the fiscal year ending June 30, 1914, were \$2,603,123; for 1915, \$2,176,668; for 1916, \$3,533,206; for 1917, \$4,561,526; and for 1918, \$1,839,173. In 1916 and 1917 the figures were swelled by large amount of railroad-construction material sent to the interior end of the line, which cannot be included in the ordinary demand, leaving an average for the other three years of \$2,172,988. As there is no important source of return freight in sight it is clear that unless we are prepared to meet a heavy deficit, the freight charges must be nearly equal to the declared value of the goods to say nothing of the ocean freight and charges on the southern portion of the line.

This is, however, only a part of the story. The railroad merely takes goods from the outside to a point in the interior, by a new route on which vastly more money has been spent than was invested in the old, and must then depend on the old river transportation system, over which it has no control, for their distribution. So far as appears from the above facts the chief advantages accruing to the Yukon population will be more convenient ways of

getting out of the country, and the saving of money due to their ability to carry smaller stocks and replenish them at any season of the year. In all other respects winter conditions will remain the same until east and west lateral railroad lines afford new facilities.

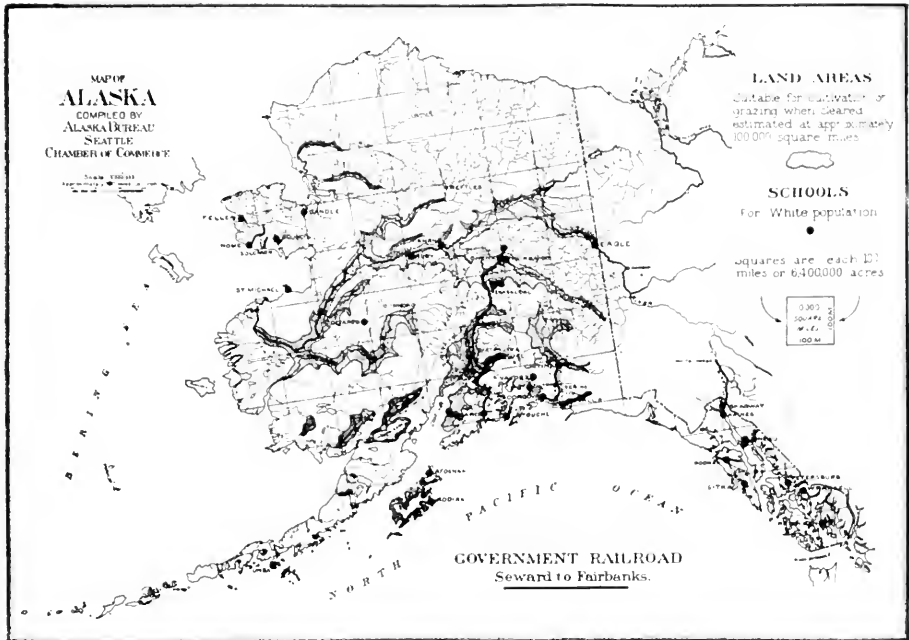

Through the irony of fate, a project based on the improvement of conditions round Fairbanks has resulted in no small part of that town moving bodily to the new town of Nenana, where the railroad first strikes the valley. Fairbanks is no longer the central distributing point. It is time that we take an inventory of the assets of the Interior Zone, so that we may intelligently undertake its future development.

PRESENT STATUS OF MINING. Were it not for the discovery of gold the Yukon Valley would still be a wilder-

would not have changed the figures so suddenly. The richest and most accessible deposits only, can be worked today, the ability to work the poorer ones when better transportation facilities were available has been lost in the steady advance in the cost of living. The oft quoted 13c, as the average yield of dredging in California is no longer the keynote.

These things have also borne heavily on lode-gold mining near Fairbanks, causing suspension of work at many mines. Finally, the interior has been rapidly depopulated by the demands of the War and the abnormally high wages paid in war industries; the population is yet far from the normal 12,000 to 15,000, although it is increasing slowly.

The agricultural industry is so intimately dependent

ness. It was the placer gold that attracted the first adventurers, and placer mining today is the dominant industry. As it prospers, so do all others; as it declines, the others wane. Lode mining for gold is conducted on a limited scale near Fairbanks under harsh conditions, and small shipments have been made of tin, tungsten, and antimony, but the price of the last two metals has fallen to a figure rendering export unprofitable, while the increased costs of all materials employed at the placer mines, as well as the higher cost of labor, have rendered much ground valueless that in normal times might have been economically worked. These things are curtailing the gold output all over the world and the Yukon Valley is not the only sufferer. A material reduction in the annual shipments, due to gradual exhaustion as indicated by the returns, was to be expected, but this cause alone

on mining that anything affecting the prosperity of the one is reflected in the status of the other. Farming in the interior of Alaska is confined to truck-gardening, the eatable vegetables being sold to the adjacent mining community, while the hay and grain is fed to the stock on the farms or at the mines. The extent of the industry may be judged from the following data. Allowing an average consumption of 1000 lb. of farm products per capita, and an average yield of only 5 tons per acre under intensive cultivation, we have a required production of not to exceed 7500 tons, requiring 1500 acres for the total quantity, equal to 15 farms of 100 acres or 150 farms of 10 acres. This area is about $2\frac{1}{2}$ square miles out of an estimated available area of 50,000—showing clearly that the industry is in its babyhood. To load a vessel of 3000 tons burden with cereal products, we must have a 25-bushel

top weighing 60 lb. per bushel on 4000 acres. It is evident that some years must elapse before this is possible, as the land is not yet cleared; it is also evident that the mining communities must enlarge greatly to furnish a living to the farmer while this is being accomplished.

Betterment of the mining industry is the first thing to be attempted. As the prospector is today, as he has been in the past and will be in the future, the searcher for new mineral, anything that will guide him in his arduous labor, preventing lost years and useless wandering in regions where neither mineral lodes nor placers are likely to be found, is of prime account. The short summer, the generally inaccessible character of the country to be explored, the absence of trails, and the dense vegetation make his task anything but a picnic. He may be an intelligent man yet unable to understand the technical language of science while perfectly able to read a good map, so that a graphic illustration, with a lucid explanation in simple English, will be of greater service than a library of scientific bulletins. The following suggestion appeals to me.

It is an accepted proposition among scientists that the upward thrust of bodies of molten or plastic rock into the overlying stratified or water-laid rocks has played a most important part in the mineralization of the latter through the solvent action of the superheated water or steam in the former. We may safely accept the truth of this axiom without going into the question as to how the minerals were dissolved by the water or precipitated therefrom. It is here sufficient to say that the staff of the U. S. Geological Survey accept this view, and that the gold deposits of Alaska owe their origin, in large part at least, to tremendous intrusive action in the early part of what is known technically to geologists as the Mesozoic era, which word means 'middle life' and indicates that the time was mid-way in the history of life on our planet. Rocks laid down later than that time could not have been affected because they were non-existent. The older rocks have therefore a special interest for the prospector and mining geologist as being most likely to contain metallic deposits of value.

Through years of patient labor, which only an enthusiast can appreciate, buffeted by storms as they forced their way through the unbroken wilderness, the staff of the Geological Survey have delimited the area of these rocks with accuracy sufficient for our purpose, and a map of the Yukon Basin showing these delimited areas would be a most valuable step in forming an estimate of the probable future of the gold industry in the Interior Zone, valuable alike to the prospector and the operator. The position of the intrusive rocks should be shown in strongly contrasting color. In a more subdued tint it would be well to show the areas of the consolidated rocks laid down since the Mesozoic disturbance, for while they could not be affected by it, later intrusions may have mineralized them to some extent and along different lines. In both areas all mineral deposits should be indicated of which mention is made in the bulletins of the Geological Survey, and the streams that have yielded placers might

be brought out prominently by a heavy black line. The rest of the map would be left uncolored. Such a map would probably be a surprise to many people who imagine that gold is to be found everywhere in Alaska, but while it is true that 'float' gold in small particles is carried by the streams in flood-time and widely disseminated, there are large areas in which the probability of finding 'pay' is so slight that prospecting in them would be a waste of time and energy. A broken line might show the limit of recent glaciation.*

The dominating idea should be to make the map as simple as possible, but a long step forward would be made, through the aid of the Agricultural Department, if those lands suitable for the plough, as distinguished from grazing, could be shown in light hatching. We could then see at a glance the economic relation between the two industries, a point of no small value when we stop to consider the dependency of one on the other. If such a plan should be found too complex, the same base map might be used by each department, on which to impose the necessary coloring, so as to avoid the annoyance of consulting the scale of the respective maps.

The Agricultural Department would do good work by issuing an economic bulletin to accompany the suggested map. It has done magnificent work and is deserving of unqualified praise, but in the very nature of things, the plots of ground on which the experimental stations were established were selected because of their supposed suitability as regarded soil, sunshine, wind, and date of killing frosts. They have demonstrated what will grow; what we now want to know is the whereabouts of similar lands, especially in the area surveyed and subdivided by the Government, so that we may be able to judge of its proximity to local markets and the northern terminus of the railroad line; the time necessary to clear an acre in terms of day-labor; the amount and type of fertilizers, if such are needed, to correct soil-acidity or other defects; the average yield per acre of the various cereals, vegetables, and root crops; the frequency with which a crop-failure may be expected, and what pests or diseases must be held under control or exterminated. The information contained in the bulletins on soil-surveys should be condensed into the language of daily life bereft of scientific technology as completely as possible, and the information furnished by voluntary observers scattered through the agricultural reports should be collected and tabulated. Crops for fodder should have a special notice, as also the small fruits that grow luxuriantly and might possibly furnish exportable products. Dairying in all its

*With such wide distribution of the metal it seems strange that the natives did not know more about it. When compiling a map of Alaska in the autumn of 1897, to supply the demands of the gold-seekers, I used the narratives of Schawtka, Dall, Allen, Stoney, Townsend, and others, and found no reference to it. Stoney foreshadowed the discovery of asphalt in the Colville region, Dall intimated the occurrence near Goodnews Bay of rocks similar to those near Dawson; and Townsend mentions iron and a contact of slate and granite rocks near the headwaters of the Kobuk river, on the strength of which I indicated that region as a possible gold district.

branches should be discussed for similar reasons, with information on silage crops and the cost of wintering not only cows and horses, but hogs and chickens; in fact, the bulletin should cover all topics relating to the food supply of the community.

Returning to the prospector, it should be remembered that there have been no inducements to seek for metal lodes. When large and low-grade they offered little inducement to large capital on account of the excessive cost of transportation and development. The effort to work the known lodes has been confined almost entirely to Fairbanks, and in that district the veins are of a type that calls for the closest economy in the management and a thorough knowledge of practical mining. While the grade of the ore is good, the tonnage has been small and most of the properties are waiting for brighter days. Good prospects in the Kantishna have been unproductive

In my opinion a great mistake was made when a standard gauge was a lot of beyond Matanuska Junction. A potential heavy traffic from the coal-fields was expected from that point south to the seaboard, but from the junction northward the line was purely exploratory, and a 3 ft. gauge like that of the White Pass & Yukon line, would have doubled the mileage for the same amount of money and have supplied a greatly increased area. Action must be prompt and liberal so as to get the good work started before the completion of the main line, because that will result in the dispersion of the working gang and a material decrease in the number of mouths to be fed by the local farmers. How complete this dispersion is and how great may be its effect on local interests was exemplified at Cordova when the railroad from that point was completed. The number of saloons dropped from 27 to 2, and other business suffered equally.

CHICKALOON MINE IN THE MATANUSKA COALFIELD, ALASKA

since their discovery a good many years ago. The prospector cannot afford to pay the fee and expenses of an expert whose report would command attention, and the capitalist will not listen unless he has such a statement before him, so that a lode-claim is to the prospector like the gift of a white elephant.

The interests of the farmer must also be studied and every possible inducement given to locate in the north. Land should be absolutely free and untaxable for a number of years. Seed of the crops best suited to each locality should be furnished free of cost by the experimental stations and farm machinery made available, as for some years to come there will be a scarcity of human labor at crucial periods, because harvest-time comes just when the placer miners are working at their seasonal clean-up.

This measure of success can alone justify the building of the Seward-Fairbanks railroad unless we look at it as a military necessity. That it must be finished and with all possible speed goes without saying, but its effect on the community will be very limited until trails and roads have been built into the mining districts; and good roads or even branch railroads into the agricultural sections.

We must be prepared to show many of these workers why they should remain in the country.

That there is a wonderful potential wealth of agriculture in the Interior Zone is beyond doubt. The difficulties in the way of making it available to the nation have been submitted to the limelight to see if they actually cast impenetrable shadows, or if we might thread our way between them and realize our hopes. No worthy enterprise has suffered from the truth being told, but so that there can be no possible misunderstanding I repeat that this article deals only with the central portion of Interior Alaska and must not be taken as a statement of conditions existing in the Littoral Zone, in which they are entirely different and infinitely more favorable at this date. The Interior Zone has produced for export only gold and a small amount of other minerals; the Littoral Zone has sent out gold and a large amount of other metals and fed hundreds of thousands from the products of the sea. All Alaska, however, suffers equally from the fact that a pitifully small portion of the wealth taken both from land and sea remains within its boundaries. The vast bulk has gone outside to build up other communities.

By-Product Coke-Ovens of the Granby Consolidated Company, at Anyox, B. C.

By W. A. WILLIAMS

*The Granby Consolidated Mining, Smelting & Power Co. is the largest producer of copper in British Columbia and consumes an average of 250 tons of coke per day. Beehive-oven coke was formerly bought, and the shipments were often considerably delayed and the proportion of breeze was excessive, causing great inconvenience in the operation of the smelter. To secure a more reliable supply, the company decided to produce its own coke. A modern coal mine was put in operation at Cassidy, a few miles from Nanaimo on Vancouver island, and a coking-plant built at the smelter. The coal is screened at the mine, the marketable sizes sold, and the slack washed and shipped to the coking-plant.

Barges holding about 2000 tons carry the washed slack to the coke-plant, where it is unloaded by a steam-hoist operating a one-ton bucket having a capacity of 120 tons per hour. The bucket is emptied into a hopper, from which the coal is carried by a 30-in. belt to the top of the 12,000-ton storage-bin, where it is distributed by another belt running along the top of the bin. The bin, built entirely of wood, is 300 ft. long and 51 ft. wide, with a V-shaped bottom. From the bin, the coal is taken by belt-conveyor and elevator to the crusher, which is one of the swing-hammer type and has a capacity of 50 tons per hour. The coal is crushed so that at least 90% will go through a $\frac{1}{2}$ -in. screen and 80% through $\frac{3}{4}$ in. A bucket-conveyor takes the coal from the crusher to the 500-ton bunkers over the ovens. The coal is drawn from the bunkers into a lorry equipped with four cone-shaped hoppers, the combined capacity of which is 13 tons, just sufficient to charge one oven.

The 30 ovens, having a capacity of 270 tons of coke per 24 hours, were designed by the Gas & Coke Oven Co. of America. Their special feature is the substitution of vertical flues for horizontal flues. The dimensions of the coking-chambers are 37 ft. 4 in. long, 9 ft. 10 in. high, 18 in. wide at the pusher side, and 21 in. at the coke side, with a capacity of approximately 13 tons of coal. Regenerators are situated under the ovens, one regenerator-chamber under each oven. A heavy wall separates the regenerator-chambers from each other and upon this wall rests the oven-heating wall. This oven-heating wall is made up of 30 vertical flues, each two adjacent flues forming a complete unit. Situated beneath these vertical flues are two ducts that feed gas to them through removable nozzles. These horizontal ducts are so divided that 14 of the vertical flues receive their gas from the coke side and 16 from the pusher side. The regenerators are

connected to waste-heat flues paralleling each side of the battery, and are so divided as to furnish air to, and receive the products of combustion from, these flues, receiving gas from the same side.

The regenerators are divided into an upper and lower section by means of a horizontal partition extending from the front of the generator chamber to within 18 in. of the back wall. Thus any tendency of the air and products of combustion to short-circuit is avoided and their travel increased. The efficiency of the generator system is greatly augmented by having this regenerator-chamber, through which the combustion air is being drawn, sandwiched between regenerators, through which the products of combustion escape, thus effecting what might be called a combined regenerative and recuperative system.

The pusher was built by the Atlas Industrial Car Co. of Cleveland, and comprises door, extractor, pushing-ram, and leveling-bar. The coke guide and door extractor on the coke side are hung from an overhead track. The quencher-car, with its load of red-hot coke, reaches the quenching station; the water is automatically turned off when the car leaves the station. After quenching, the coke is taken directly to the screening-station where it is separated into furnace and breeze coke and loaded directly into cars. The handling is greatly facilitated by the fact that, owing to difference in elevation of the quencher and loading-tracks, the cars are loaded by gravity.

The gas is reversed each half-hour, burning in one flue of each unit for half an hour, and in the other flue for the next half-hour. Thus we have combustion taking place in every alternate flue the whole length of the oven-wall. The size of the opening connecting the two flues comprising a unit is regulated by a slide-brick, thus controlling the air-supply to that particular unit. Above each flue is a hole through which the condition and temperature of the wall may be observed. The openings leading from the regenerator to the stack-flues are provided with dampers so that the draft to each regenerator may be regulated.

The incoming combustion-air is regulated by the use of finger-bars. There is a damper in each stack-flue just before they unite into a single flue at the stack-end of the ovens. The single flue that leads to the stack also contains a damper. The stack is built of radial brick. It is 177 ft. high and 9 ft. 8 in. diam. at the bottom and 7 ft. diam. at the top.

The gas is conducted from the oven-chamber through 14-in. cast-iron ascension pipes to the collecting main, which is 4 ft. 4 in. wide, and 4 ft. 9 in. deep at one end

*A paper read before the Canadian Mining Institute at Vancouver on November 27, 1919.

and 5 ft. 8 in. deep at the other, with a semicircular bottom. The uptake main is 28 in. diam. and continues just beyond the bunkers, where it enters the downtake, which is 24 in. diam., and thence along the ground by the by-product building.

A hand-valve to control pressure in the collecting-main is placed just before the downtake. The temperature of the gas is considerably reduced in the collecting-main and the heavier particles of tar and liquor condense and escape as a liquid. To keep the main free from thick tar and pitch, fresh tar is continuously circulated through it.

On reaching the by-products building, the gas enters the primary coolers, of which there are three, each containing 594 three-inch outside-diameter lap-welded steel tubes 17 ft. long. The water flows through the tubes and the gas around them. The temperature of the gas is re-

duced to 32°C . and most of the tar and liquid is deposited. The gas now enters the exhausters, whose function it is to maintain an even pressure in the collecting main and to force the gas through the remaining apparatus. The exhausters, three in number, were built by the Commersville Blower Co., and are driven by 10 by 10 in. vertical self-oiling Troy steam-engines, equipped with Hunton float-governors so as to maintain a pressure of 1 to 2 M.M. in the collecting main.

The exhausters have a displacement of 17 cu. ft. per revolution and are designed to operate at 250 r.p.m. against a total plus and minus pressure of $2\frac{1}{2}$ lb. per square inch.

After leaving the primary coolers, the gas still holds tar in suspension in the form of minute globules called 'tar fog'. The removal of these last traces is accomplished by means of a P. & A. tar-extractor, which consists of a series of perforated steel plates, so arranged that the gas passing through the first plate will impinge upon the non-perforated part of the second plate. The impact causes the very fine particles to coalesce and run down the plate.

From the extractors the tar free gas goes to the saturators, which are lead lined cast-iron containers, where it is made to pass through a bath containing 5% to 7% sulphuric acid. The ammonia in the gas reacts with the acid to form a white crystalline salt, ammonium sulphate, which settles to the bottom of the saturator and is removed to the drain table by means of an air-ejector. From the drain-table the salt is conducted to a centrifugal dryer, where it is washed with water to remove the free acid and then dried.

The liquor and the tar which condenses owing to cooling of gases in the various parts of the process are pumped to a separating-tank of 45,000 gal. capacity, where the tar and liquor separate by specific gravity. The liquor overflows into a 50,000-gal. tank and the tar is drawn off from the bottom to a 200,000-gal. tank. The tar is pro-

THE COKING-PLANT OF THE GRANBY CONSOLIDATED COMPANY, AT ANYOX, B. C.

duced at the rate of eight gallons per ton of coal.

The liquor, which contains about one-fifth the total ammonia produced, is treated in a continuous still where the ammoniacal vapors are liberated. These vapors are also passed through the saturator, which is so constructed that the waste gases that accompany the ammonia vapor from the still may pass into the main gas-stream, leaving the saturator, or to be conducted into the atmosphere.

The free leg of the ammonia still is made up of three 21-in. cast-iron sections and one 15-in. section, all resting upon the liming-chamber, which is 6 ft. high. The internal diameter of all sections is 4 ft. 3 in. and the total height of the free leg is 15 ft. The fixed leg is made up of two 21-in. sections and one 15-in. section of the same diameter as those comprising the free leg. Each section is provided with a vapor-passage through the bottom, covered with serrated edges, and an internal overflow for liquor passing to the next lower section.

Each section is provided with hand-holes by means of which access can be had to every part of the interior so that the apparatus may be readily inspected and cleaned.

The liquor enters the top of the still and drops from section to section; the steam which enters at the bottom, as well as any liberated vapors, pass through the vapor passages and bubble through the liquor at the edge of the food. The boiling liquor from which the free ammonia has been expelled, is mixed with milk-of-lime in the lime-chamber and caused to flow into the fixed leg where the remaining ammonia is liberated. The escaping liquor contains 0.033% to 0.007% ammonia.

The saturator is provided with a heater for the mother-liquor; this may be used to maintain the temperature of the bath in case the still is not running or to heat the bath when starting a saturator. Under normal working conditions the heat of the ammonia vapors from the still and the heat of dilution of the sulphuric acid, are sufficient to maintain a temperature of 45 to 50°C. The salt produced averages more than 20 lb. per ton of coal, and contains at least 25% ammonia and less than 0.2 of 1% free acid.

From the saturator the gas passes into the final coolers, which are 40 ft. high and 10 ft. diam., and are of the direct-contact type. The water not only cools the gas but mechanically washes out much of the naphthalene.

To recover the light oils, the gas is scrubbed with straw-oil, a petroleum product, in the hurdle washer 75 ft. high and 14 ft. diam. The slats composing the hurdles are 5 in. wide, $\frac{3}{4}$ in. thick, and spaced $\frac{3}{4}$ in. apart; thus the gas in passing through the scrubbers flows in thin streams over surfaces that are continually wet with the absorbent. The travel of the gas and oil is counter-current. The oil is pumped to the top of the scrubber and flows zig-zag down over the hurdles, while the gas enters at the bottom and leaves at the top; thus the partly de-benzolized gas is brought in contact with the fresh wash-oil, which is able more efficiently to remove the small amount of light oil yet remaining and likewise the partly benzolized oil is brought in contact with the rich gas and its light contact-oil increased. The amount of wash-oil circulated depends upon the number of cubic feet of gas produced and its light-oil content, and is of such an amount as to keep the light-oil content of the benzolized wash-oil between 2 and 3%. The benzolized oil is stored in a 3000-gal. tank, from which it is pumped to the stripping-still.

The de-benzolized oil leaves the still at about 130°C., and, before it is re-circulated, its temperature is reduced by a system of heat exchangers and coolers to about 20°C. The de-benzolized wash-oil leaving the bottom of the still and the light-oil vapors leaving the top of the still each contain a considerable amount of heat, which is transferred to the incoming benzolized oil. The benzolized wash-oil is pumped to the vapor-oil heat-exchanger.

From the vapor-oil exchanger, the partly heated benzolized oil joins the oil to oil heat-exchanger, where its temperature is increased by the de-benzolized oil leaving the still. After leaving the oil to oil heat-exchanger, the benzolized wash-oil enters a superheater where its temperature is raised to 110 to 150°C. This superheater furnished by the Alberger Heater Co. of Buffalo, New York, is 8 ft. long and about 20 in. diameter.

The hot benzolized oil now enters a stripping-still which is continuous in its operation. The still is made up of seven sections, each section being 123 in. high and 1 ft. 4 in. diam. The hot oil enters the eight sections from the bottom and passes down the still rapidly, giving up the light oil it contains. Steam is admitted in the bottom section and passes through the still, bubbling under the sealing bells of each tray and carrying upward the light oil in the form of vapor.

As noted before, the de-benzolized oil, on leaving the still, passes through the oil-exchangers, where it gives up some of its heat to the incoming benzolized oil, then to the wash-oil coolers, of which there are two, a tank-cooler containing two $\frac{1}{2}$ -in. steel pipes 22 ft. long, and a spray-cooler consisting of sixty 2-in. steel pipes 9 ft. long. From the cooler the oil goes to the de-benzolized-oil tank and is now ready for re-circulation.

From the 23,000-gal. light-oil storage-tank, the light oil is pumped into the crude-oil still, which consists of a horizontal cylindrical kettle holding 3800 gal. and a fractionating column of 14 sections resting on a separate foundation. Heat is supplied by means of indirect steam through sixteen $1\frac{1}{2}$ -in. extra-heavy pipes 13 ft. 10 in. long, placed in the bottom of the kettle so that the direct steam may be used when desired. The presence of live steam lowers the boiling-point and is necessary when the toluol and solvent fractions are reached.

The operation of the raw-oil still depends upon whether motor-fuel or pure products are to be produced. The first portion to distill is often discarded because of the carbon bisulphide it contains. When making pure products the crude distillate is divided into 90 benzol, 90 toluol, and solvent naphtha.

These crude products are then transferred to a lead-lined agitator where they are washed with sulphuric acid for about thirty minutes, after which about another thirty minutes is allowed for the used acid to settle. The acid is used to separate the unsaturated hydro-carbons, principally olefines. After the sludge is run off the benzol or toluol is washed with water and any acid remaining neutralized with caustic soda.

The washed products are now ready for rectification in the pure-oil still. This is similar to the crude-oil still in construction but greater care and skill is required in its operation. Each 1000 gal. of light oil will produce about 500 gal. C.P. benzol, 100 gal. C.P. toluol, and 100 gal. refined solvent naphtha. When making motor-fuel, the benzol, toluol, and such higher portions as will give a finished product that will distill to complete dryness at not over 135°C. are caught in the same receiver. After the crude motor-fuel has been run off, there still remains a solvent naphtha fraction, boiling at from 130° to 170°C. The crude motor-fuel is also washed with sulphuric acid, but not so thoroughly as in the case of pure products. This washed motor-fuel is then run through the pure-oil still in order to remove the last traces of water and any foreign substances that do not settle after washing. The products made are coke, gas, tar, ammonium sulphate, benzol, toluol, solvent naphtha, and naphthalene.

Chloride Roasting and Leaching at the Plant of the Tintic Milling Company

By THEODORE P. HOLT

The plant is situated in the Tintic mining district, about 100 miles south of Salt Lake City, Utah. It is controlled by Jesse Knight and was built originally to treat the low-grade ores of the Knight mines. This mill, being on the Eureka Hill, Denver & Rio Grande, and Los An-

gles, the ore coming to the mill is weighed on standard railroad scales and dumped into one of nine receiving-bins. These are hopper-bottomed, each having a steel-apron feeder which delivers the ore to a 24-in. belt-conveyor. This discharges over a 2-in. grizzly to a No. 2 gyratory crusher and through three sets of 16 by 36-in. rolls. The ore, reduced to 4-in., is next elevated to the sampler. The samplers are of the Vezin type, designed to give a two-hundredth cut. After sampling, the ore is delivered to one of six storage-bins by a tripper-conveyor. Three of the bins are for sulphide ore and three for oxide. In addition, there are bins for salt and coal-dust.

Each bin is served by a variable-speed belt feeder. By proper regulation of the feeders a suitable admixture of oxide and sulphide ore is obtained, with about 9% salt and 2% coal-dust. This passes through 16 by 36-in. finishing-rolls, which gives a final 6-mesh

THE TINTIC MOUNTAINS, LOOKING UP FROM THE MILL.

gles & Salt Lake railroads, is in a position to serve all the mines of the district, and at the present time receives ore from some twenty different properties.

Construction of the mill was started in the summer of 1915, and the plant began to operate in the following February. Owing to the use at first of a down-draft furnace, which gave unsatisfactory results, the plant treated only a small tonnage until the following year. It has now milled more than 250,000 tons and has demonstrated the profitable treatment of refractory low-grade ores. Earlier descriptions of the mill will be found in the technical press,* the present description of the improved plant will be readily understood by reference to the accompanying flow-sheet. See Fig. 1. The ores of Tintic vary widely in character. In general, they have a hard, silicious gangue with silver as the principal metal, together with some gold, copper, and lead.

*Trans. A. I. M. E., Vol. 49, p. 183; 'M. & S. P.', Aug. 29, 1914; and 'E. & M. J.', Feb. 6 and 13, 1915.

YARD, TRACKS, AND COVERED ORE-BIN AT THE MILL.

product. A shuttle-conveyor distributes the ore to a long bin above the Holt-Dern roasters.

There are eleven roaster units, each chloridizing about 20 tons per day. The roasting is the vital operation in the process, since if the metals are properly chloridized they are quickly dissolved in the leaching operation. A pivoted-bucket carrier serves all the furnaces and elevates the roasted product to chutes, where it is sluiced

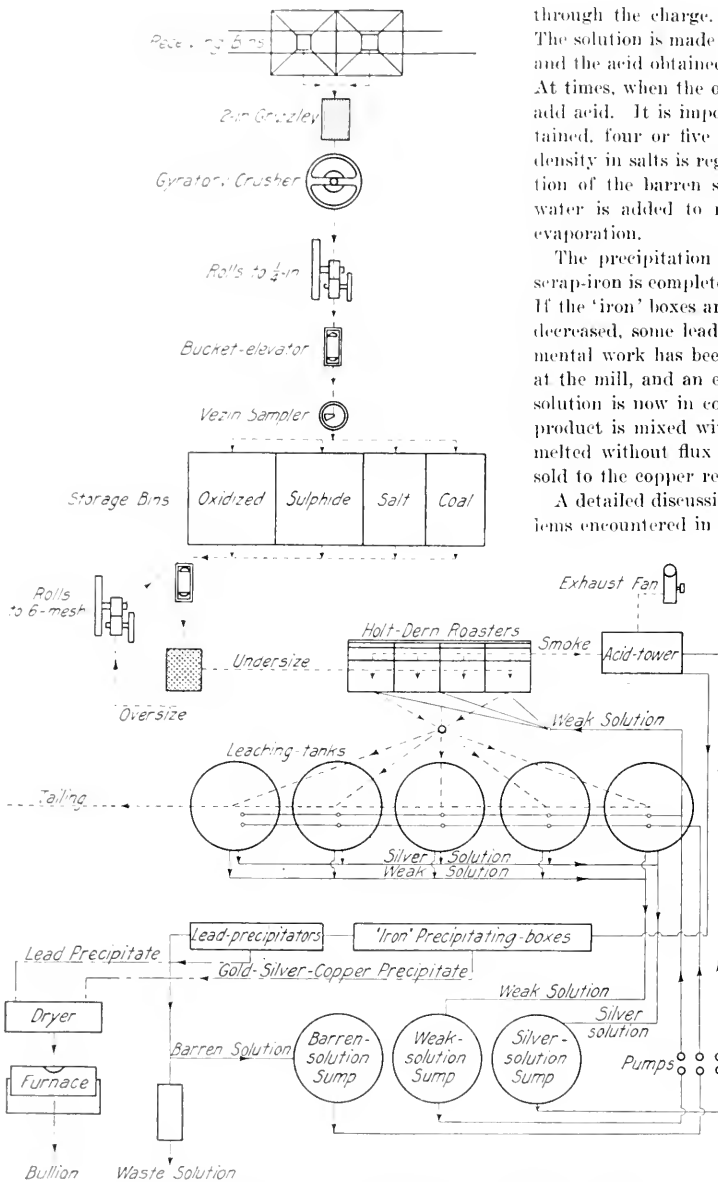

FIG. 1. FLOW-SHEET OF THE ROASTING AND LEACHING PLANT

with mill-solution to the leaching-tanks. The original plan was to charge the tanks with dry ore, but sluicing is preferable for several reasons. The more important are the elimination of dust and the effective heating of the mill-solutions.

There are 12 leaching-tanks, 20 ft. diam. by 11 ft. deep. The porous character of the roasted product is such that no difficulty is experienced in getting the solution

through the charge. The leaching operation is simple. The solution is made up of the soluble salts in the calcine and the acid obtained from the smoke from the furnaces. At times, when the ore is high in lime, it is necessary to add acid. It is important that a slight acidity be maintained, four or five pounds per ton being ample. The density in salts is regulated by wasting a certain proportion of the barren solution each day. Sufficient wash-water is added to replace that discarded and lost by evaporation.

The precipitation of the gold, silver, and copper on scrap-iron is complete before any of the lead comes down. If the 'iron' boxes are too long, or the rapidity of flow is decreased, some lead is deposited. Considerable experimental work has been done on the precipitation of lead at the mill, and an electrolytic plant to handle the mill-solution is now in course of construction. The iron-box product is mixed with a small amount of coal-dust and melted without flux to a copper-silver bullion, which is sold to the copper refinery.

A detailed discussion of the various metallurgical problems encountered in the operations of the mill is outside the scope of this article. Some reactions that work beautifully in the laboratory have been found impossible of duplication in the mill. For example mill-solution carrying a little free chlorine gave a good extraction of the gold when carried out in the laboratory. In the mill the results were erratic and the control of the gas proved a serious matter. Since the gold present in the low-grade ore is usually less than \$1 per ton and about 35% of this is recovered in the regular treatment, it is obvious that any practicable scheme must operate at a low cost. After three years of experimental work, it was determined to sluice the tailing to a separate plant and to treat it with a lime-wash, followed by cyanidation. The consumption of both lime and cyanide was much lower than would be expected. However, meanwhile the advance in the silver market has made it possible, for the present, to refuse

all shipments of ore containing much gold, so that the erection of the cyanide annex has been postponed.

The presence of lime is objectionable, not only on account of the acid consumed, but because of its active dechloridizing action in the roast. This action is well shown in the graph, Fig. 2. To guard against 'high-lime' ores, a penalty of 30 cents per unit is charged on all lime in excess of 3% contained in the ore. This figure

is obtained from the analysis for CO_2 , the result being calculated in terms of CaCO_3 . Sulphide ore is at a premium in the Tintic district, and to encourage the

FIG. 2. GRAPH SHOWING THE EFFECT OF LIME ON THE EXTRACTION

shipment of low-grade sulphide the mill allows a credit on all the sulphur in ore containing 6% or more.

The Rakha Hills Mines

At present copper is being mined by only one company in India, the Cape Copper Co., whose Indian property—the Rakha Hills mines—has now reached a stage at which it seems practically assured of success. Some 45 years ago copper ore was mined by the Nerbudda Coal & Iron Co., and a certain quantity of ore was shipped to England; but the lodes were not large enough, nor sufficiently persistent, to justify a continuance of operations, and the mine was ultimately abandoned. It is interesting to note, however, that several of the early samples yielded from 12.6 to 47.8% copper, the average being 28%. At Rakha Hills there are no rich lodes like this, nor is such high content necessary to maintain successful operations. But a big body of copper ore has been proved and, worked by modern methods, there is little doubt that it will turn out to be of commercial importance. The property, which was formerly known as the Rajdoha, is situated in the Singhbhum district of Bengal, Chota Nagpur. The Cape Copper Co. exercised its option to acquire the property in March 1913, the idea being that it would perhaps make good the diminishing output from the famous O'okiep mine in Cape Colony. Excellent progress was reported up to the time the War broke out, the equipment of the mine being then within a few months of completion; and at the main shaft about 250,000 tons of ore, containing

something like 10,000 tons of copper and some gold, was actually opened up. Then came the War, which upset all plans. If the mine had only been producing copper at the time everything would have been well. The company would have been unaffected by the high freight-rates then ruling, because its supply of fuel is obtained in India, within quite a reasonable distance, and the market for its product is also local; it would also have had the benefit of high prices for copper. As it was, however, one obstacle after another arose, the completion of the plant was delayed, and work at the mine had practically to be brought to a standstill, because the company could not stand a continual drain upon its resources. In December 1918, however, the converter-plant started work, and in July 1919 the refinery-furnace was completed and put in operation. For several months the company has been producing and selling refined copper; and in this connection it is noteworthy that higher prices are obtainable for copper in the Indian market than in England, owing to the 7½% Indian import duty and the cost of freightage to Great Britain. At the annual meeting in December last, T. Blair Reynolds, the chairman, said that the company was now freed from the drain of remittances which, at an increasingly adverse rate of exchange, were necessary in order to keep the establishment going through the slow process, during the War, of erecting the refining plant. Mr. Reynolds added that he did not expect that the estimates on which Rakha was laid out would be realized at once—there were dislocations, he said, in India as elsewhere, and it would take time to get into normal running. The ore-reserves actually opened up and ready for extraction are now stated to amount to 384,294 tons, carrying 3.76% copper, which is equivalent to about 14,500 tons of copper, the average width of the lode being 3 ft. 6 inches.

SOME interesting discoveries have been made by British investigators in connection with mine-rescue apparatus. The apparatus is supplied with oxygen to make up for the foulness of the atmosphere through which the rescuer moves in a mine where there has been an explosion. Experiments with the rescue apparatus indicate that the extra supply of oxygen will enable the average man to walk faster and with greater comfort than is possible in the open air, even without the weight of the apparatus. Trials made with miners, however, bring out the unexpected fact that men who were accustomed to the atmosphere of mines do not find the same benefit. It is thought that their lungs have become adapted, through years of hard physical labor, to make fuller use of the oxygen in the atmosphere and therefore additional oxygen is not so helpful.

A PLATINUM determination is a difficult one for an assayer to make with his regular equipment. Samples of material in which the presence of platinum is suspected should be sent to a reliable chemist who is accustomed to such work. Many ores which have been reported as platiniferous by local assayers, have proved barren after the material was analyzed by more elaborate methods.

The Swansea Mill

By F. Le Roi THURMOND

THE Swansea mine is located at Swansea, Arizona, 28 miles north of Bouse, a station on the Phoenix cut-off of the Santa Fe system. A standard-gauge railroad, the Arizona and Swansea, extends from Bouse to Swansea. An old smelter with blast and reverberatory furnaces testifies to the "romance" of mining, a quality which seems to have greatly encumbered this property in the past. The mine and mill are operated by the Swansea Lease Incorporated. Jack Bruce is superintendent of the mine and Lyman F. Barber of the mill.

The ore is chalcopyrite in a gangue consisting mostly of specular hematite with small amounts of pyrite, chlorite, calcite, kaolin, quartz, and tale. The specular iron is very soft and friable and much of it can be broken in the hand. Chalcopyrite is associated with it. The chlorite, calcite, kaolin, and tale come from masses of unreplaced country-rock enclosed in the ore, and from portions of wall-rock which become mixed with the ore.

The ore from the mine is dumped onto a 4 by 8-ft. flat grizzly, with bars spaced $2\frac{1}{2}$ in., set over a 1000-ton bin. All but about 10% of the ore falls through the grizzly. The oversize is put through a 12 by 16-in. Blake crusher. From the bin the ore is fed with a steel conveyor-feeder onto a belt-conveyor, which discharges into the scoop-feed of a ball-mill. The ball-mill is 6 by 6 ft. made by the Allis-Chalmers company and operated by a 90-hp. motor through a short-centre belt-drive at 26 r.p.m. Two-inch chrome-steel balls are used. The discharge from the ball-mill goes to a No. 30 Dorr Duplex classifier, which returns the oversize to the mill. The overflow goes to a Minerals Separation flotation machine of 16 cells, driven by a 55-hp. motor. The shaft makes 390 r.p.m. The impeller-shafts are geared down in the ratio of $1\frac{1}{2}$:1, giving a peripheral speed of 812 ft. per minute.

Base oil is fed with the ore to the ball-mill, in the amount of $\frac{1}{8}$ lb. per ton of feed. The oil is P. & E. No. 1, sold by the Gilmore K. & K. Oil Co. of Los Angeles. A mixture of No. 5 and No. 8 pine-oils in the ratio of 40:60, furnished by General Naval Stores Co., is fed to the classifier return, in the amount of $\frac{1}{4}$ lb. per ton of original feed. Trona, a natural sodium sesqui-carbonate from Searles lake, is used as a flocculating agent. It is charged into the bin with the ore in amounts varying from 8 to 12 lb. per ton of ore.

The pulp going to the flotation machine has a dilution of $2\frac{1}{2}$:1, the feed being split between the second and fourth cells. The froth from the second to sixth cells, inclusive, is a finished product and is elevated to a Dorr thickener that feeds an Oliver filter. The cake from the filter goes directly to the shipping-bin. Froth from the 7th to 16th cells is returned to the first cell for cleaning and constitutes the entire feed to that cell. Froth from this cell joins that from the primary cells as it goes to the thickener. The tailing from the flotation machine goes to waste.

Samples are cut from classifier overflow and from the

concentrate and tailing launders every 15 minutes. The copper content of the mill-heading during the month of January, averaged 2.3%; tailing averaged 0.05%, giving an extraction of approximately 98%. Notable as this result is, it has been exceeded for weekly periods and by individual operators, one man making 98.9% extraction for a week, and all operators for 24 consecutive shifts making a tailing of less than 0.01% with a concentrate assaying 24% copper. The figures for the month of January 1920, are tabulated below:

Tons milled	7800
Heading assay, % Cu.....	2.30
Tailing assay, % Cu.....	0.05
Concentrate assay, % Cu.....	22.54
Extraction, %	97.80
Oil used per ton, lb.....	0.75
Total cost per ton.....	\$0.95

The cost per ton has not been itemized but covers everything including crushing and loading the concentrate into cars. The concentrate is shipped to the Consolidated Arizona Smelting Co. at Humboldt, Arizona. An average assay of the concentrate is as follows:

	%		%
Cu	22.25	CaO	2.00
Fe	30.00	Zn	Trace
SiO ₂	2.50	An	None
Insoluble	2.40	Ag	0.40 oz.
S	29.00		

Fluctuations in the character of the ore, in the amount of trona, and in the speed of the flotation machine are responsible for variations in results. Some of the ore shows incipient oxidation, and this causes a loss both of oxide and oxide-coated sulphide particles but deeper mining should eliminate this difficulty. Even better results are expected in future operations.

ACTIVE WORK was begun in December on the iron mines of Las Truchas property in Michoacán. 10,000,000 tons of ore is calculated as the minimum amount recoverable from the deposit. The company expects to reach an output of 5000 tons per day. Plans already proposed include the building of a standard-gauge railroad from the pit-mouths to the sea, and the construction of a harbor for the shipment of the ore. Since this shipping point is on the open sea, the improvements contemplated will require, perhaps, two years of dredging work, the construction of a breakwater, and either wharves or a quay, with at least 32 ft. of water at the berths.

CANADA has been the world's third largest producer of platinum during the last three decades. As most of the Canadian supply is obtained from the refining of blister-copper from the Sudbury mines, this portion of the production has not been credited to Canada, but chiefly to the United States, where the process of refining has been largely carried on. Native platinum has been found in various parts of western Canada, chiefly in the Tulameen district of the Similkameen mining division, from which, during the years 1887-1891, an average annual output of 1500 oz. was recorded.

The Friction of Ventilating Currents

By WALTER S. WEEKS

INTRODUCTION. The proper ventilation of metal mines is recognized today as an economic necessity. Ventilation is an old story to the coal-mining engineer, but it is either a new or a long-forgotten question to the metal-mining engineer. My purpose is to lay before the busy engineer the salient points of the subject, in the hope that ventilation projects may be worked out upon sound principles and in the hope that accurate data may be gathered to piece out our present meagre information. I shall deal entirely with mechanical ventilation.

Let us start with the simple problem of driving air through a tunnel that passes entirely through a hill. See Fig. 1. When air flows through such a passage, friction on the top, bottom, and sides of the tunnel retards the air so that an appreciable pressure must be maintained at the entrance to keep the air moving. The entire surface against which the air rubs is called the rubbing surface and is denoted by S . It is measured in square feet and is obtained by multiplying the perimeter of the section by the length of the tunnel.

It has been found that the resistance to flow varies with the square of the velocity. It has also been found that the resistance varies directly with the density of the air. It has also been found that the resistance varies with the character of the rubbing surface. Thus we see that the resistance to flow is a function of a number of variables.

If we denote the velocity in feet per minute by V , the density in pounds per cubic foot by d , and take into consideration the effect of the character of the walls by a constant, C , the resistance to flow may be thus expressed:

$$R = C d S V^2$$

R is the resistance measured in pounds.

The factor d varies so little in comparison with the other factors, that a standard weight of air is assumed and d and C are combined to make the familiar constant K . So the usual form of the equation is

$$R = K S V^2$$

Some treatises on ventilation say that K is measured in pounds per square foot, while others say that it is measured in pounds. K is not measured in any units. It is a constant that takes care of all the factors not denoted by symbols in the equation. The bewildering mass of contrary statements in the literature makes a simple subject appear abstruse.

From this fundamental formula the other formulas that deal with the friction of the air are derived.

The problem of moving air is the problem of pumping water through a horizontal pipe. We have to deal only with frictional resistance and velocity changes. For the present we shall consider friction alone.

Now let us suppose that we have connected to the entrance of the tunnel a large compressor with a frictionless piston of exactly the same size as the tunnel. If

we run this compressor with a piston speed of V , the air in the tunnel will flow with a velocity V . In order to run the compressor we must exert a thrust on the piston equal to R , which is the frictional resistance in pounds.

If the area of the piston is A square feet, the unit-pressure on the piston is $\frac{R}{A} = \frac{K S V^2}{A}$. This unit-pressure is denoted by p and is measured in pounds per square foot. It is the drop in pressure in pounds per square foot undergone by the air in passing through the tunnel.

THE AIR-PRESSURE. We should measure this pressure with a water-gauge. A water-gauge is a U tube of glass with water in it. The gauge would be placed outside the tunnel and one leg would be connected by a rubber tube to the inside of the tunnel at the entrance. The difference in level of the water in the two legs would indicate the difference in pressure between the air at the entrance of the tunnel and the atmosphere. This pressure would be read in inches of water, but it can be converted into any unit of pressure.

Suppose we have a cube of water measuring $1 \times 1 \times 1$ ft. This cubic foot of water would weigh about 62.3 lb., and hence there would be a pressure on the base of the tube of 62.3 lb. per square foot. If we divide the cube into 12 horizontal sections it will be seen that each section exerts $\frac{62.3}{12} = 5.2$ lb. per square foot. So if we denote the water-gauge in inches by i we have the useful relation

$$p = 5.2 i$$

p , as it will be remembered, is the unit-pressure in pounds per square foot.

The next question that interests us is: how much power is required to circulate the air?

Work = Force \times Distance.

Work per minute divided by 33,000 is horse-power.

The distance per minute that the piston of the compressor moves is V feet, so the work per minute that is necessary to move the piston is $p \times A \times V$.

$p \times A$ is the force on the piston.

But $A \times V = Q$, or the quantity of air flowing per minute.

Consider an opening of A square feet. If a column of air flows through the opening with a velocity of V feet per minute, in one minute the amount that will have passed through is $A \times V$, or Q .

So in any drift or tunnel where the drop in pressure is p pounds per square foot and the quantity of air in circulation is Q cubic feet per minute, the work per minute is $p Q$, and the horse-power is $\frac{p Q}{33,000}$. This value is often spoken of as the horse-power 'in the air'. It would

For the actual power of the motor necessary to overcome friction if our fan and motor were 100% efficient.

If we were dealing with a drift in a mine, instead of a tunnel, it would be less easy to measure the resistance, but if the drift were the same size and length as the tunnel, the amount of the resistance would be the same. In some way we should have to connect one leg of the water-gauge to the entrance of the drift and the other leg to the end of the drift. The difference in level of the water in the two legs would indicate the drop in pressure in the drift. The problem of measuring p in the case of

FIG. 1 Section

FIG. 3 Plan

the tunnel was simple because the end of the tunnel was at atmospheric pressure.

SPLITTING THE AIR. Let us now suppose that the tunnel is divided into two divisions inside of the hill, as shown in Fig. 2. a is one portal and c is the other. A fan situated at a is forcing Q cubic feet per minute into the tunnel. How much air will flow in division No. 1 and how much in division No. 2? This is the problem of the natural splitting of air.

Where a current of air is divided into several branches, these branches are called 'splits'. Natural splitting means the division of the air current without the introduction of regulators in the air-ways to control the flow. The pressure at b is the pressure at the beginning of both splits and the pressure at c is the pressure at the end of both splits; hence the drop in pressure in each split must be the same.

We have shown that the drop in pressure p in any air-way is $\frac{K S V^2}{A}$. If we designate the drifts by subscripts, 1 for division No. 1, and 2 for division No. 2, then

$$\frac{K S_1 V_1^2}{A_1} = \frac{K S_2 V_2^2}{A_2}$$

From this equation the following relationship can be deduced:

$$\frac{Q_1}{Q_1 + Q_2} = \frac{.11 \sqrt{\frac{A_2}{K S_1}}}{.11 \sqrt{\frac{A_1}{K S_1}} + .12 \sqrt{\frac{A_2}{K S_2}}}$$

To the expression $.11 \sqrt{\frac{A}{K S}}$ is given the name of 'pressure potential' of the split.

The law of natural splitting, then, may be stated thus: The quantity of air flowing per minute in a given split is to the total quantity flowing in all the splits starting at

FIG. 2 Plan

FIG. 4 Plan

the same point and ending at the same point, as the pressure potential of the given split is to the sum of the pressure potentials of all the splits.

$$Q_1 + Q_2 = \text{total air flowing.}$$

The velocities of the air in the two splits will so adjust themselves that the drop in pressure in the one will equal the drop in pressure in the other.

The rule applies to any number of splits.

The derivation of the formula may be of interest. It is given on the next page.

CONTROLLED VENTILATION. Suppose we must meet the conditions illustrated by Fig. 3:

Air-way	Size Ft.	Length Ft.	Air desired per min.
			Cu. Ft.
$a-b$	8×8	1000	36,000
1	6×6	2000	18,000
2	4×4	1000	8,000
3	5×5	3000	10,000
$c-d$	9×9	500	36,000

We have here a fixed set of conditions. We wish a definite amount of air to flow in each drift. What will be the pressure that the fan must maintain at a , and how will the air be controlled?

The first operation is to calculate the drop in pressure from *b* to *c* in each split with the assigned amount of air. The split that has the greatest drop is called the 'free' split and will be left open. A difference in pressure equal to this drop must be maintained between *b* and *c* in order to force the required amount through the free split. But this difference in pressure will be greater than the calculated 'drops' in the other two splits, so the air in these splits will speed up to make the loss of pressure in these splits equal to the loss in the free split. This will give us more air than we need, so we must put restrictions in these splits in order that when the desired amount of air is flowing the drops in all three splits will be the same.

The total pressure on the mine is obtained by adding the drop in pressure from *c* to *d*, the drop in pressure in the free split, and the drop in pressure from *a* to *b*. The actual calculation will make this clearer, but we cannot

$$\frac{K S_1 V_1^2}{A_1} = \frac{K S_2 V_2^2}{A_2}$$

Take the square root of both sides

$$V_1 \sqrt{\frac{K S_1}{A_1}} = V_2 \sqrt{\frac{K S_2}{A_2}}$$

Multiply the left side by $\frac{A_1}{A_1}$ and the right side by $\frac{A_2}{A_2}$

$$A_1 V_1 \sqrt{\frac{K S_1}{A_1^3}} = A_2 V_2 \sqrt{\frac{K S_2}{A_2^3}}$$

Substituting Q_1 for $A_1 V_1$ and Q_2 for $A_2 V_2$

$$Q_1 \sqrt{\frac{K S_1}{A_1^3}} = Q_2 \sqrt{\frac{K S_2}{A_2^3}}$$

$$\frac{Q_1}{\sqrt{\frac{A_1^3}{K S_1}}} = \frac{Q_2}{\sqrt{\frac{A_2^3}{K S_2}}}$$

$$\frac{Q_1}{\sqrt{\frac{A_1^3}{K S_1}}} = \frac{Q_1 + Q_2}{\sqrt{\frac{A_1^3}{K S_1} + \frac{A_2^3}{K S_2}}}$$

$$\frac{Q_1}{Q_1 + Q_2} = \frac{A_1 \sqrt{\frac{A_1}{K S_1}}}{A_1 \sqrt{\frac{A_1}{K S_1}} + A_2 \sqrt{\frac{A_2}{K S_2}}}$$

DERIVATION OF FORMULA

make any calculations until we have assigned a value to K .

DETERMINATION OF K .

$$K = \frac{p a}{S V^2}$$

If we take a given length of drift of uniform section

and measure the velocity of the air flowing and the drop in pressure undergone by the air in this length, these quantities, with the rubbing surface, will enable us to evaluate K . Such experiments have been made.

The value of K varies with the character of the rubbing surface. In drifts with smooth walls it is lower than in drifts with rough walls. Many investigations indicate that the shape and size of the section of the drift influence the value of K .

The time-honored value of K is known as the Atkinson coefficient and its value is 0.0000000217. This value is too high for the average drift. T. W. Fitch, Jr., before the West Virginia Coal Mining Institute in June 1910, gave the following values:

0.000,000,003,6 for air-passages that are concreted, wood-lined, or of exceptional smoothness, and untimbered, straight, regular, and free from obstructions.

0.000,000,007,3 for air-passages that are untimbered, fairly smooth, straight, unobstructed, and regular in size.

0.000,000,010,9 for air-passages that are untimbered and moderately crooked, irregular, obstructed, and rough.

0.000,000,014,6 for air-passages that are timbered, but otherwise fairly smooth, straight, unobstructed, and regular in size.

0.000,000,018,2 for air-passages that are timbered and moderately crooked, irregular, obstructed, and rough.

0.000,000,021,9 for air-passages that are timbered, and very crooked, irregular, and rough.

The value of K may be still higher than the last given in cases of air-ways in extremely bad condition.

F. Ernest Braekett, in an article in the 'Engineering and Mining Journal', April 22, 1911, entitled 'Friction of Air in Mines', has prepared a workable table of values of K in such a way that the shape and size of the section are given weight.

It is evident that the validity of such calculations depends upon the selection of the proper values of K . The determination of K for the types of openings found in metal mines is an investigation that should be undertaken.

We shall now calculate the problem in controlled ventilation, using the Atkinson value of K .

Drift No. 1.

$$\begin{aligned} p &= \frac{K S V^2}{A} \\ S &= 24 \times 2000 = 48,000. \\ V &= \frac{Q}{A} = \frac{18,000}{36} = 500. \\ p &= \frac{0.0000000217 \times 48,000 \times 250,000}{36} \\ p &= 7.23 \text{ lb. per square foot.} \end{aligned}$$

Drift No. 2.

$$\begin{aligned} p &= \frac{K S V^2}{A} \\ S &= 16 \times 1000 = 16,000. \\ V &= \frac{8000}{16} = 500. \\ p &= \frac{0.0000000217 \times 16,000 \times 250,000}{16} \\ p &= 5.43 \text{ lb. per square foot.} \end{aligned}$$

Drift No. 3.

$$p = \frac{K S V}{A}$$

$$S = 20 \times 3,000 = 60,000,$$

$$V = \frac{10,000}{25} = 400,$$

$$p = \frac{0.0000000217 \times 60,000 \times 160,000}{25}$$

$$p = 8.33 \text{ lb. per square foot.}$$

Drift No. 3 will be the free split, and doors with adjustable apertures must be placed in No. 1 and No. 2 to increase their resistance. These apertures must be adjusted until the correct amount of air is flowing.

The difference in pressure between point *b* and point *c* will be 8.33 lb. per square foot.

The amount of pressure that we must waste in the regulator in drift No. 1 is

$$8.33 - 7.23 = 1.1 \text{ lb. per square foot.}$$

The amount we must waste in the regulator of drift No. 2 is

$$8.33 - 5.43 = 2.90 \text{ lb. per square foot.}$$

Drift *a = h*.

$$p = \frac{K S V^2}{A}$$

$$S = 32 \times 1000 = 32,000,$$

$$V = \frac{36,000}{64} = 562.5,$$

$$p = \frac{0.0000000217 \times 32,000 \times 31,640.6}{64}$$

$$p = 3.43 \text{ lb. per square foot.}$$

Drift *c = d*.

$$p = \frac{K S V^2}{A}$$

$$S = 36 \times 500 = 18,000,$$

$$V = \frac{36,000}{81} = 444.4,$$

$$p = \frac{0.0000000217 \times 18,000 \times 197,491}{81}$$

$$p = 0.95 \text{ lb. per square foot.}$$

The total pressure that must be maintained by the fan to overcome friction is then

$$3.43 + 8.33 + 0.95 = 12.71 \text{ lb. per square foot.}$$

A water-gauge at the fan would read

$$\frac{12.71}{5.2} = 2.44 \text{ inches of water.}$$

The horse-power necessary to overcome friction is

$$\frac{12.71 \times 36,000}{33,000} = 13.9.$$

Assuming a 60% efficiency for fan and motor, the horse-power of the motor would be 23.2.

I have purposely neglected all discussion of velocity-heads because I think it will be easier to take up that subject after we have considered the centrifugal fan.

The ramified workings of a mine may not look like a group of splits at first sight, but with a little patience they may be grouped into primary splits. These primary splits may be made up of secondary splits, and so on. In a group of splits the free split is the only one that figures in determining the mine pressure, so we can

gradually work down to the single air-course that offers the greatest resistance and so determine the mine pressure. This is shown diagrammatically by Fig. 4. The capital letters indicate points and the small letters sections of drift between the points. A given amount of air is assigned to each section and the drop in pressure in inches of water is marked on each.

At the point *B* two primary splits begin and these are divided into the secondary groups *c d e* and *h i k*.

Let us look first at the secondary splits. Of the secondary splits on the left side, *d* has the greatest resistance and of those on the right *i* has the greatest resistance. The resistance of these free secondary splits will be used in determining the resistance of the primary splits.

The difference in pressure between *C* and *E* must be 3 inches.

The difference in pressure between *D* and *F* must be 4 inches.

Drop in pressure from *B* to *G*

$$\text{via } b d f = \frac{1}{2}'' + 3'' + 5'' = 8\frac{1}{2}''$$

$$\text{via } g i m = 2'' + 4'' + 2'' = 8''$$

Regulators may be placed as follows:

Left Side. *b, d*, and *f* will be open.

Regulator in *c* will waste 2 inches.

Regulator in *e* will waste 2½ inches.

Right Side. *i* and *m* will be open.

Regulator in *g* will waste ½ inch.

Regulator in *h* will waste 2 inches.

Regulator in *k* will waste 3 inches.

A water-gauge on a pressure-fan at *A* will read 9½ inches

In closing this discussion let us calculate a problem in the natural splitting of air. Referring to Fig. 2, let us suppose that division No. 1 is 1500 ft. long and its section is 5 × 7 ft. Let division No. 2 be 1000 ft. long and its section 8 × 8 feet.

The total air in circulation is 10,000 cu. ft. per minute. How much will flow in division No. 1 and how much in division No. 2.

$$\frac{Q_1}{Q_1 + Q_2} = a_1 \sqrt{\frac{a_1}{K S_1}}$$

$$a_1 \sqrt{\frac{a_1}{K S_1}} = a_2 \sqrt{\frac{a_2}{K S_2}}$$

If the *K* is the same in both drifts we may cancel it.

$$a_1 \sqrt{\frac{a_1}{S_1}} = 35 \sqrt{\frac{35}{36,000}} = 1.09$$

$$a_2 \sqrt{\frac{a_2}{S_2}} = 64 \sqrt{\frac{64}{32,000}} = 2.86$$

$$\frac{Q_1}{Q_1 + Q_2} = \frac{1.09}{3.95} = 0.276$$

Amount flowing through Div. 1 = 0.276 × 10,000 = 2760

Amount flowing through Div. 2 =

7240

Let it be clearly understood that we have dealt entirely with the pressure necessary to overcome the friction of the air in the mine. It may be necessary to supply additional pressure to increase air-velocities in the mine. I shall discuss this subject in a later paper.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

THE SHATTUCK-ARIZONA COMPANY IS DEVELOPING PROPERTY IN SONORA.

BISBEE.—The Irish Mag Leasing Co. is about to resume operations on the C. & A. lease of that name, under an agreement made by local people who will finance the undertaking.

It is announced by the Shattuck-Arizona company that

to 25 oz. silver with occasional high grade pockets. These are to be developed.

KINGMAN.—Tony Hill, developer of several successful mines, has taken over the Gold Button mine in the Aubrey district and will commence development work immediately. Several shallow shafts have been sunk on the property.

MIAMI.—It is reported that the Van Dyke Copper Co.'s

INTERNATIONAL SMELTER AT MIAMI, ARIZONA

conditions in the Shattuck-Arizona mine are rapidly approaching normal following the flooding of the mine below the 700-ft. level to extinguish the fire of last year. The mine is now operating one 8-hour shift and approximately 300 tons per day of lead-copper ore is being mined. The Shattuck shaft is to be sunk 200 ft. and development is planned for the 1000 and 1200-ft. levels. An option to purchase the Con. Virginia property, a silver prospect situated in Sonora, Mexico, 125 miles south of the boundary, has been obtained. The property comprises 246 acres of mineral-bearing territory and is situated in the Sierra Madre mountains east of the town of Moctezuma. It is said to have a splendid surface showing and shallow prospect holes show ore which assays 5

shaft, which is being sunk to the east of the Miami fault, is now down 1210 ft. and has passed through 30 ft. of carbonate which has become high-grade shipping ore in the shaft bottom. It is stated that this ore is in Pinal schist under the Gila conglomerate and is the same ore as that passed through by the No. 1 drill-hole put down in the spring of 1917.

SUPERIOR.—Clearing ground for the new power-plant of the Queen Creek Copper Co. is well advanced. The machinery for the plant has been ordered and delivery is expected immediately. The present inclined shaft is down 800 ft. Rich copper and gold ore was opened on the 400-ft. level.

YUMA.—It is stated by W. J. Johnson, the owner of

the New King of Arizona property, that rich gold ore has been opened. Machinery is now being shipped to the mine to develop and mill the ore.

COLORADO

THE MINING SITUATION IN CRIPPLE CREEK.

CRIPPLE CREEK.—A. E. Carlton, president of the Golden Cycle Mining & Reduction Co., in a letter accompanying the April dividend checks, announces a reduction of the dividend rate to two cents, \$30,000 in place of \$45,000 commencing May 10. The Portland has cut its dividend from \$60,000 to \$45,000 monthly and the Vindicator company has passed its quarterly dividend and will conserve its treasury reserve to be used for development purposes. Discussing this action the letter says:

Appreciating that many of the stockholders in our company were largely dependent upon the income from their investment, your directors have continued dividends on the basis of three cents per share monthly. As the earnings for some time past have not been sufficient to meet the dividend requirements, it was necessary to use reserves, largely accumulated by the sale of various investments and property of the company.

We have now reached a point where further dividends on the present basis would leave the company without sufficient working capital, and your directors have determined to reduce the dividend rate beginning May 10, to the basis of two cents per share monthly.

A large part of the Cripple Creek ore has been produced by lessees, who have been gradually forced to suspend until now, few, if any, are operating. Development work has not been possible, and the output continues to decrease. The Golden Cycle Mining & Reduction Co. owns approximately 40% of the United Gold Mines property, one of the most valuable in Cripple Creek. The company also owns some 3000 acres of coal land six miles north of Colorado Springs, containing 15,000,000 tons of developed coal, and now producing in excess of 200,000 tons per annum. The company also owns the Golden Cycle mill, with an ore capacity of 40,000 tons per month.

MAYDAY.—A number of prospects are being developed in the district and some ore is shipped regularly. Charles Morris, contracting on the Little La Plata, which is being operated under bond and lease by W. A. Beeker, has driven 135 ft. of cross-cut. This work is being done to explore the Little La Plata at depth. No ore has yet been found. Charles Curtet and Joe Moigg, lessees on the Southern Boy, are driving a cross-cut to gain depth on an orebody exposed in a shaft where they have worked during the past eight months. After being practically closed down for two weeks, the Jumbo is again shipping. The Mayday, which has been idle for several years, will begin operations about May 1, with a force of 25 men, it is said.

LEADVILLE.—High-grade gold ore, contained in 50 sacks, with an estimated value of \$50,000, from the property of the Rex Mining Co., at the Ilex mine on Breese Hill, were brought to the city and placed in the vault of the Carbonate National Bank for safe keeping. The ore was mined by eight Austrians, operating under

lease. Since the discovery was made last February, the lessees have been shipping steadily, but the sacked ore is the richest taken out to date.

A new corporation, the Leadville Silver Mines Co., has secured control of the Emmett property in California gulch above the Yak tunnel, and holdings in Poverty flats. High-grade ore has been mined on the Emmett and the new company, organized by Florence N. Doty, S. P. McDonald, and George Bennett, well-known Leadville operators, plans extensive development. The new wage-scale of \$4.50 per day has gone into effect, and the shortage of miners has been relieved, as many men have returned to the district.

MICHIGAN

HANCOCK.—SENECA.—FRANKLIN.

Houghton.—Operations at the Hancock property continue to be confined to the territory east of the main Pewabic lode. General physical conditions are improving. While the company is not operating as many drills and is therefore not able to carry forward its exploration program upon the scale anticipated, the results to date have been satisfactory. The showing on the No. 12 amygdaloid is encouraging. This lode was opened in a cross-cut from the 44th level. Drifts in both directions continue in mineralized ground which contains copper ore comparable to the general run of the Pewabic lode proper. Stopping ground will be opened from this level. The machines operating on No. 3 lode are in fair ground. Efforts to connote the geological tendencies of this broken area continue to offer serious problems. The identification of No. 15 conglomerate was positive, but aside from this recognized fact the other lodes are doubtful.

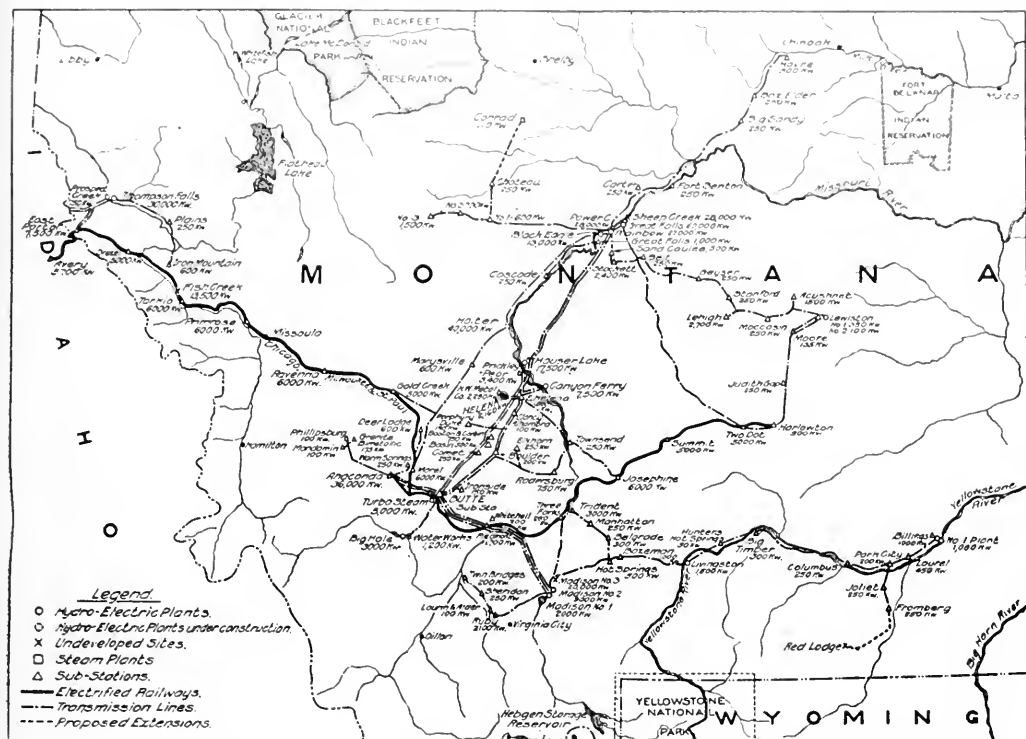

Seneca resumed sinking in the main shaft on April 10. The work is progressing rapidly and will permit early opening of the fourth level. The shaft now has attained a depth of 2100 ft. Resumption of the mining on the third level will start immediately. The cross-cut to the lode was through before the shaft-sinking was suspended to permit concreting. Drifts both north and south on the vein will be started immediately. The longitudinal work on the fourth level to tap the Kearsarge amygdaloid will not take long and then there will be two openings at that depth. It is planned to carry the shaft down to 2600 ft. rapidly. There will then be eight levels from which development may proceed. Diamond-drill work, carried on from surface, to find out just what ore the Calumet conglomerate, the Osceola amygdaloid, and the other lodes that traverse the property may contain has been concluded with the results stated. The diamond-drill work, which is being conducted in the Gratiot shaft, has not yet progressed to a point where there is assurance of ore. This work is going forward on the sixth level. Sinking the Gratiot shaft will be undertaken on May 1.

Hancock.—Progress in the 39th level drift in the Allouez conglomerate at the Franklin mine continues in ore that will produce 25 lb. per ton. The north drift now is in 400 ft. The rich material is found in true formation for a distance of 100 ft. For the first 250 ft. of the

north drift the character of the formation was not particularly encouraging. Beyond was good rock which has steadily improved in character. Going back in the drift the raises opened practically the same rich ore as that found farthest north. Continued development in these raises shows ore all the way along, proving that the north lateral, for the first 250 ft., was simply below grade. These raises continue in good ground and give further support to the expectation that this rich streak of copper

REMINE.—New York interests have taken over the Lee Mountain property for further development. The mine is opened by a series of drift tunnels 850 ft. long by means of which a depth of 600 ft. has been obtained. The production record of the mine is conservatively placed at \$1,500,000.

BEAVERHEAD COUNTY.—The Argyle Silver Mining Co., operating in the Vipond district, hopes to begin operation by May 1. The Argyle shaft has been re-timbered, the

MAP OF WESTERN MONTANA

will be found to continue from the 30th to the 39th level. The south drift has been started in good-looking ground.

MONTANA

CONSTRUCTION STARTED ON THE NEW MILL OF THE BOSTON & MONTANA DEVELOPMENT CO.

PHILIPSBURG.—The regular producers in the Philipsburg district include the Granite Bi-Metallic, Scratch-all, Williams & Hickey, and the Dolan mines. The Bi-Metallic is shipping three to five cars of manganese, and four to five cars of silver ore daily. A shaft is being sunk on the True Fissure property; 500 miners are working in the district at present.

LUMP CREEK.—With the work of re-timbering of the Free Coinage shaft completed, sinking will be continued to a depth of 1000 feet.

hoisting machinery overhauled, and the mine workings cleaned up. J. Benton Leggat is president.

WHITEHALL.—The Jefferson Mines Co. reports the discovery of a high-grade orebody containing copper, gold, and silver on the Dorothy claim. A large area is held, including the Dorothy, Sunlight, and Lamplight claims. Ore on Clark's Fork is said to assay \$8 per ton, the shoot extending for a considerable distance. Denver capital is behind a new development scheme for the district.

EAST HELENA.—Four large furnaces are being operated at the A. S. & R. plant, 1000 tons of ore per day being smelted.

BUTTE.—The Anaconda company's production of copper for the month of March totaled 18,450,000 lb. The Boston & Montana Development Co. has started construction of a 500-ton mill and concentrator. The foundation is already in with the machinery and supplies on hand.

Two tunnels tapping the mine reach the principal veins at 400 ft. and 1200 ft. Several years supply of low-grade ore has been blocked out, and 150 men are employed on construction and development work.

NEIHART.—High-grade silver ore, in a vein 18 in. wide, is reported to have been opened on the Neihart Consolidated property while sinking the shaft.

NEVADA

LESSEES ON THE FLORENCE ARE MINING HIGH-GRADE ORE.

GOLDFIELD.—Two hundred tons of ore of an average value of \$100 per ton is being hoisted for shipment from the Cracker Jack lease on the Florence, according to official statements made by the Florence and Cracker Jack managements. Most of this ore has come from a short distance above the 358-ft. level, where there is a stope 35 ft. long in a shoot of erratic width and richness. Several mine carloads of ore assaying as high as \$500 per ton have been broken in this stope as a result of careful mining. This find was made in territory cut by numerous old workings and there is little chance for the shoot to produce a large tonnage. On the 400-ft. level, with conditions good for a persistent orebody, a shoot has been opened for a length of 50 ft. and for an equal depth by a winze. The drift and winze have shown the average width of the ore to be 18 in. and the average value \$100 per ton. The vein is from 1 to 4 ft. wide. At the north end of the drift there is 1 ft. of ore assaying \$416 and at the south end there is 3 ft. assaying \$300 and 8 in. assaying \$545. On the 500-ft. level a raise has been driven 50 ft. in ore assaying from \$28 to \$36 in gold and containing 4% copper. On the 165-ft. level of the old Rogers lease, shaft a 3-ft. width of ore of an average value of \$380 has been opened. Eight working faces are being advanced in the lease. These finds are the result of prospecting since January 1. Hundreds of feet of development work has been done since then, consisting principally of cross-cuts and raises into the walls of stopes in a search for parallel shoots in the Consolidated-Florence vein. A number of other lessees are using machine drills and the bonanza levels in the vicinity of the former main productive territory should be exhausted by the first of next year. After making connection with a lease shaft for ventilation purposes the Florence company has resumed driving of the west cross-cut, now 1000 ft. long. At 725 ft. from the shaft a drift has been started in a vein in which ore was found years ago in the Moore lease.

MONTEZUMA.—The shaft of the Montezuma Silver Mines Corporation, at a depth of 303 ft., is in low-grade silver-lead ore, the assays from a width of 18 in. varying from \$15 to \$45. The shaft is damp, but there is no indication that the water-level is near. Drifts have been started east and west from the bottom of the shaft and a cross-cut will be driven into the foot-wall of the vein from one of them. While rich ore has been opened under exceptionally promising conditions, there is nothing exposed in the shaft at present to indicate that the company has more than an excellent prospect, with better than an average chance to open more ore in the foot-wall

of the vein and at greater depth. The greatest width of the vein occurred in the centre of the shaft, which at a number of places reaches the proportions of a stope. Ore still shows on the foot-wall side of the shaft, but practically all has been removed and on the east and west sides the vein nowhere has a width of more than two feet. Previous reports of an extreme width of 4½ ft. were made while the bottom of the shaft was in a bulge in the vein, which continued for only a short distance.

DIVIDE.—Ore 4 ft. wide, 3 ft. assaying \$85 and 1 ft. assaying \$330, has been found at a depth of 310 ft. in the Victory. The find was made in the main Tonopah-Divide vein, 240 ft. north-west of the shaft. The drift has been advanced 15 ft. in ore of similar grade and a cross-cut has been started to determine the width of the vein. The cross-cut being driven on the 400-ft., or bottom level, of the East Divide is near the objective of many months work, a vein striking north. This vein has a prominent outcrop on the claims of the East Divide. Conditions in the Alto continue promising, particularly in the north drift on the 400-ft. level, but an important orebody has not been found.

CACTUS.—The shaft of the Cactus Nevada is 270 ft. deep and a contract has been let for sinking an additional 100 ft. A station is being cut at the 265-ft. point and the cutting of the vein at this depth will be of importance, as it will determine whether there is an improvement in the broken condition of the vein found on the 165-ft. level.

WEST DIVIDE.—One and one-half feet of low-grade silver-lead ore has been entered in a drift being driven in the vein at a depth of 150 ft. in the West Divide, indicating that ore of good grade may be found when the drift has been advanced under where high-grade ore was found at a depth of 65 ft. in the shaft. Driving of the south drift from the shaft has been resumed and conditions are improving, although the ore still is in narrow seams.

MANHATTAN.—The vein in the White Caps is being prospected at a depth of 800 ft. Conditions are reported to be similar to those on the 600-ft. level and assays of from \$20 to \$25 in gold have been obtained. The ore contains stibnite, an antimony tri-sulphide containing gold; realgar, an arsenic mono-sulphide; and orpiment, an arsenic tri-sulphide. Arsenical ore is now being shipped from the sixth level.

SIOSTONE.—What is said to be a valuable deposit of kaolin is reported to be under investigation by the Standard Oil and Armour companies. The deposit is owned by O. L. Ray, prominent in Bullfrog and Jarbidge during the early days of those districts.

UTAH

COAL PRODUCTION.—NEW MILLING PLANT AT EUREKA.

SALT LAKE CITY.—The coal mines of the State, in spite of the slackening-up that usually comes with the advent of spring, are working at about 85% of normal capacity, according to John Crawford, coal mine inspector, who has just returned from a trip to Carbon county, the largest coal-mining district in Utah. The output of coal from Utah mines in January broke all records, while the

February production was almost as large, and did break the record so far as daily output is concerned. Labor conditions are satisfactory, and coal miners are making high wages.

A revision of the itinerary of Bureau of Mines car No. 11, which has spent the past six months in Utah, and is now at Battle Mountain, Nevada, has been announced as follows: At Battle Mountain until April 24; en route to Salmon, Idaho, April 25 to May 1; Salmon, May 2 to 8; Gilmore, May 9 to 15; Driggs, May 16 to 22; Mackay, May 23 to 29; Hailey, May 30 to June 5. R. V. Agerton, engineer in charge of the car, has gone to Houghton,

000 was paid during the year to Simon Bamberger for the 'Fortuna' group of claims, and the remaining \$25,000 will be paid on or before July 1, 1920. In his report, Mr. Ballantyne states that all of the company's efforts were devoted to the development of the mine through the main tunnel from the Bingham side, which is opening the property at depth. A total of 2267 ft. of such work was done. The revenue to the company from ore sales was \$72,000, which, with miscellaneous income, brought the gross income for the year up to \$74,284. Lessees shipped ore of a total value of \$9148. During the first six months of the year, the property was operated at a loss of \$10,661, while during the last months, an operating profit of \$26,531 was realized, making a net profit for the year of \$15,870 from mining operations. The company has a contract for the purchase of the Tiwauke group of claims for \$37,500, which carries a penalty of \$10,000 per annum until the full consideration is paid.

EUREKA.—Three feet of ore, which averages better than \$50 per ton, was cut recently in a drift on the 800-ft. level at the Eureka Bullion property. When first entered the ore was from 12 to 18 in. wide and was found to be going almost straight down. A winze was started on the ore, and in a few feet it had widened to three feet, with indications that it was making from the fissure into the surrounding brecciated limestone.

Shipments from this district during the week ending April 10 increased to 173 earloads, as compared with 151 earloads for the previous week. The Chief Consolidated shipped 39 cars; Dragon, 29; Tintie Standard, 29; Iron Blossom, 16; Eagle & Blue Bell, 16; Colorado, 12; Gemini, 6; Grand Central, 6; Victoria, 5; Centennial-Eureka, 4; Bullion-Beck, 2; Mammoth, 2; Silver Peak, 1; Empire, 1; Tintie Mill, 1 ear bullion; Gold Chain, 1; Sunbeam, 1; Swansea, 1; and Godiva, 1.

Just about a year ago work was begun in earnest at the property of the North Standard Mining Co. During this time the shaft has been sunk to a depth of 525 ft. and 1400 ft. of drifting and cross-cutting has been done. At present the face of the east drift to the north-south fissure is but a few feet from the intersection, according to the opinion of John M. Manson, general manager. The face of the west drift along the same break to another north-south fissure is now 155 ft. from the main drift. Work is being done in three faces. Samples from the east drift on the 500-ft. level assay 32 oz. silver and 19% lead.

C. C. Griggs, who recently returned here to construct a milling plant for the treatment of low-grade ores from the May Day and Uncle Sam mines, has secured a long-time lease on the entire upper workings of the Yankee Consolidated property, adjoining, which ensures an ample supply of ore for some years. Mr. Griggs has incorporated what will be known as the Griggs Huish Leasing Co., with a capitalization of \$125,000. It is proposed by the new company to completely overhaul and remodel the present milling plant of the May Day company. This plant has an ideal location, it being possible to tram the ore directly from the May Day, Yankee, and Uncle Sam mines. A small amount of work will be necessary to

Michigan, to take charge of car No. 10. His successor has not been appointed, but in the meantime G. W. Grove will have charge of car No. 11.

BINGHAM.—The Montana Bingham Consolidated Mining Co. has issued a detailed statement covering the affairs of the company for the year 1919. At the annual meeting held recently in Salt Lake City, C. G. Ballantyne was re-elected president; E. A. Vail, vice-president; J. B. Mossman, secretary and treasurer; W. E. Hubbard, L. B. McCornick, Imer Pett, and John A. McCandless, additional directors. Since last September, the management of the mine has been in the hands of an executive committee consisting of Messrs. Ballantyne, Vail, and Pett. Announcement was made at the meeting that \$75,-

complete needed connections. The incorporators of the Griggs Huish Lensing Co. have arranged a profit-sharing feature for employees; not only those engaged in the operation of the mill, but in the mining and handling of ores. Under this arrangement, the employees will receive the earnings from 20% of the capital stock, and will also be entitled to representation on the Board.

The directors of the Iron Blossom Mining Co. on April 10 declared a dividend of $2\frac{1}{2}$ cents per share, payable on April 26. This will call for the payment of \$25,000. Another of the Knight properties, the Dragon Consolidated, will pay a dividend of 1 cent per share on April 26. This will call for the payment of \$18,750.

PARK CITY.—Shipments from this district for the week ending April 10 totaled 2182 tons, as compared with 2098 tons for the week ending April 3. Judge Mining & Smelting shipped 554 tons; Silver King Coalition, 523 tons; Ontario Silver, 609 tons; Daly-West, 333 tons; Daly, 108 tons; and Naildriver, 33 tons.

In the last hundred feet, the Spiro tunnel at the Silver King Consolidated has passed through two water-courses and entered mineralized ground. It is said that there is every indication that the bore is entering the fissured zone which strikes south-west from the old Consolidated workings and the Silver King Coalition, and the discovery of ore is now a possibility at any time. Usual progress is not being made, owing to the scarcity of miners. On April 1 the tunnel was 12,500 ft. from the portal and within 2500 ft. of the Comstock shaft.

ALTA.—Repairs have been made to the power-line serving the Emma mine so that pumping operations have been resumed and all danger of the mine being flooded has been passed, according to George Dern, general manager. Most of the power used by this property comes from the Utah Power & Light Co.'s plant in Big Cottonwood canyon, the power-line running over the mountain from the Cardiff mine. This line was carried away by the recent snowslide on the properties of the Sells and Wasatch mining companies. Immediately after the accident, the Emma company put a force of 20 men at work to make a temporary connection with the Wasatch Mines power-line. Before the necessary connection could be made, water filled the lower workings of the Emma to the 200-ft. level.

At the annual meeting of the stockholders of the Howell Mining Co., Thomas L. Walden was elected president and general manager; M. J. McGill, vice-president; Harry Deming, secretary and treasurer; James Burke and Thomas Paul, additional directors.

BRITISH COLUMBIA

NEW LITIGATION INVOLVING THE DOLLY VARDEN PROPERTY.

VANCOUVER.—The Federal Department of Justice has refused to disallow the Dolly Varden Mines Railway Act, 1919, passed at the last session of the Provincial legislature, by which the Dolly Varden mine was awarded to the Taylor Mining Co. subject to conditions, which previously have been discussed. Upon receiving this information from Ottawa the attorney for the Dolly Varden

Mines, Ltd., immediately issued two writs; one asks for a series of declarations setting aside the act and all proceedings taken under its provisions, and the other asks for damages for alleged trespass and for the payment to the plaintiff of all moneys realized from ores produced from the mine. The Taylor Engineering Co. and the Taylor Mining Co. are made defendants to both actions, while the incorporators of the Taylor Mining Co., A. J. Taylor, H. C. Chime, John Anderson, C. M. Rolston, J. F. Tener, and R. P. Buchart, are added to the defendants. Fortunately for the good of the Province and of the north-western district in particular, no injunction to prevent continuance of work has been asked. The Taylor Mining Co. had planned to increase its capital, for the purpose of erecting a modern concentrating plant at the mine, extending the railway, and adding to its equipment. It is possible that the suit may interfere with this plan for the present.

GRAND FORKS.—The Granby Consolidated M. S. & P. Co. has decided to completely close and dismantle the Phoenix mines and Grand Forks smelter. Any machinery that can be used at Anyox or Cassidy will be removed to one or other of those places and the rest will be offered for sale. According to the last report, there is still some 3,000,000 tons of low-grade ore in the Phoenix mines, and for some time the company has been considering the advisability of erecting a concentrating plant to treat this material. The ore, however, is of so low a grade that the enterprise would be a doubtful one with the copper market in its present state. The Canada Copper Corporation is advertising the sale of the Greenwood smelter. At one time the citizens of Greenwood thought of forming a syndicate to buy the smelter, so as to preserve the local industry, but this idea seems to have been abandoned. It looks as though the Boundary district is going to lose its smelting industry, which has been the mainstay of Greenwood and the surrounding neighborhood for more than 20 years.

ROSSLAND.—The whole of the surface buildings and plant of the White Bear mine was destroyed by fire on April 5. The property was purchased by the Consolidated M. & S. Co. some months ago, and the underground workings have been connected with those of the company's other Rossland mines, so the fire, though it entails a loss of about \$30,000, will not interfere with operations at the mine. Only development work is being done by the company in this district at the present time. Charles Hanson and W. H. Rhomberg have purchased the Crowned King group of claims, on Front creek, in the Nelson division. Some rich gold ore has been taken from the property.

STEWART.—The Pacific Coast Development Co. is carrying on development of the Big Missouri and is taking in supplies over the snow so that the possibility of transportation difficulties in the summer will be obviated. P. W. Racey has been appointed engineer in charge of the properties of the Silver Creek Mines, Ltd.

HAZELTON.—The opening of a new vein of two feet of good milling ore is reported by the operators of the Silver

Standard mine. Development is continuing. Necessary alterations and repairs have been made to the mill and operations have commenced, some silver-lead and silver-zinc concentrates already being ready for shipment. Because of this early start the milling season will be six weeks longer than usual.

KAMLOOPS.—A car of high-grade ore from the Joshua mine of the Donohue Mines Corporation awaits shipment to the Trail smelter. Additional concentrating machinery is to be put in to bring the capacity of the plant up to 25 tons per day.

YMR.—The Mining Corporation of Canada has taken up its bond on the Yankee Girl property and develop-

being accumulated, as the management is generally disposed to follow a conservative policy instead of making too lavish a distribution of dividends. The older Cobalt companies, which are approaching the exhaustion of their ore-reserves, are largely investing in new properties so as to be in a position to continue elsewhere when their present holdings are worked out.

PORCUPINE.—The Hollinger will make a start this season on the development of the Miller-Middleton property, bordering on the Porcupine Crown and Moneta locations. There are a number of veins on the surface and others have been determined by diamond-drilling. At the McIntyre vein No. 5, which is being developed on

THE COPPER LEAF MINE IN THE TINTIC DISTRICT, UTAH

ment, it is stated, is to be done on a considerable scale. Last December this company took a conditional bond on the Yankee Girl and subsequently A. W. Newberry, of New York, made an examination. It is understood that there will be a new corporation known as the Texas Yankee Girl Mining Co., under which the mine and adjoining mineral property will be developed and operated.

GRAND FORKS.—The Provincial government has decided to undertake some diamond-drilling on properties at Franklin, situated close to Grand Forks. The Mitchell Diamond Drill Contracting Co. is preparing to start work under the direction of P. B. Freeland, district engineer, as soon as weather conditions permit.

ONTARIO

REPORTS FROM NORTHERN ONTARIO ARE ENCOURAGING.—
LABOR SHORTAGE AT SUDBURY.

TORONTO.—Recent annual reports of the leading gold and silver mines of Northern Ontario are of a decidedly encouraging character, indicating that the industry is on a satisfactory basis. Large surpluses are in some cases

the 1250-ft. level, shows higher gold content than on the upper levels. The shaft has reached a depth of 1550 ft., and will be continued to 2000 ft. Cross-cutting is being carried on at the 1375 and 1500-ft. levels to tap No. 5 vein. The mill-heading is averaging about \$11 per ton and some 600 tons is being treated daily. The company has now a full force on the payroll.

COBALT.—The Nipissing during March mined ore of an estimated value of \$384,723 and shipped smelting ore of an estimated value of \$136,771. The annual statement of the Beaver Consolidated for the fiscal year ended February 29 shows a production of 301,781 oz. of silver, as compared with 385,042 oz. in the previous year. The profits were \$158,215. During the year large bodies of milling ore have been opened up, which it is profitable to work at present prices, and some high-grade shoots have also been found. The proposed sale of the assets of the University mine to the La Rose Mines has been stayed by a temporary injunction granted to the minority shareholders. The La Rose already owns 98% of the stock, and it was arranged to hand over the assets in discharge of a liability of \$61,000. The minority shareholders con-

tend that the deal is an unfair one and an infringement of their rights. Additions and improvements to the mill of the Temiskaming have increased production and an average of 100 tons per day is now being treated. At the Genesee a winze is being sunk from the 500-ft. level down to the contact, estimated to be at a further depth of 110 ft. The vein which is being followed carries from 2 to 6 in. of 400-oz. ore. The Rochester mine has been leased by R. H. Lyman, who will begin exploration work at once.

During the year 1919 the Trethewey mine produced

THE LOOKOUT MINE, YUKON TERRITORY. THE ARROWS INDICATE THE ADITS

\$169,294, and realized a net profit of \$31,814. This compares with a net profit of \$106,872 for the previous year. The company, having sold its property for \$100,000 early in the current year, is now devoting its entire attention to the development of the Castle properties in the Gowganda district. It is stated that these properties are now practically self-supporting.

The McKinley-Darragh has submitted a quarterly financial statement for the first quarter of 1920, before some of the less business-like companies have issued their annual reports for the calendar year 1919. The same is true of the Kerr Lake Mining Co., which early this month

issued a half-yearly report for the period August 31 to February 29. McKinley-Darragh finances as of the first quarter are summed up as follows: Cash in bank, \$203,394; Canadian victory-loan bonds, \$100,000; ore in transit and at smelter, \$127,700; ore at mine ready for shipment, \$43,570; making a total of \$474,864 in cash and realizable assets.

The Kerr Lake Mining Co. announces that it has acquired a majority interest in a silver mine in Utah as well as a gold-dredging property in New Zealand. It is stated that the Utah property commenced production last December and is equipped with a mill with a capacity for 150 tons of ore daily. Ore in sight is estimated at 87,000 tons, and is said to contain 18 oz. silver and 80c. gold per ton. The name of the mine is not given. The New Zealand property is said to have been thoroughly tested, and it is estimated that the net profits from the alluvial deposits will amount to at least \$3,436,000, after deducting the cost of the property and equipment.

The Coniagas Mines will pay a dividend of 2½% on May 1, plus a bonus of equal amount. The double disbursement will amount to \$200,000, and make the total to date \$10,040,000.

PENSE TOWNSHIP.—A report that discoveries of silver have been made in Pense township, lying about 25 miles north of New Liskeard and south-east of the Boston Creek area, has resulted in a rush of prospectors. Upward of one hundred claims have been staked and recorded, largely by representatives of Toronto interests. Details of the reported discoveries are lacking, but according to reports of the Ontario Bureau of Mines, the geological conditions are highly favorable and the finding of silver ore is considered probable.

SUDBURY.—The International Nickel Co. is unable to procure sufficient unskilled labor in Ontario owing to the exodus of foreign laborers in large numbers. Arthur Desantels, assistant manager, has gone to Winnipeg to secure men. The wages offered are 53c. per hour for muckers and 59c. for semi-skilled workers.

YUKON

THE LOOKOUT MINE.

MAYO.—The Lookout mine is situated near Lookout mountain, on Big Horn creek, a tributary of the McQuesten river, which flows into the Stewart. The mine is 26 miles from Mayo, a good wagon road connecting the two points. The elevation is 3500 ft. above tidewater. A crew of 12 men has been developing all winter and will deliver about 300 tons of high-grade galena ore at Mayo for shipment as soon as navigation opens.

The working tunnel is 700 ft. below the top of the hill. The middle tunnel is 250 ft., and the upper opening is 300 ft. up the hill. All the development has been done by local men and local capital and indications point to the Lookout being a steady producer. The assays run from 20 to 310 oz. silver per ton and 70% lead, the average being about 75 oz. silver. The property includes six claims each 1500 ft. square and a smaller fraction.

CALIFORNIA

Amador County.—At the annual meeting in London the following official statement of operations at the Plymouth Consolidated was made:

W. J. Loring has handled the labor situation with the same tact and skill as in the past, and as a result he has succeeded in obtaining the number of men required, although, owing to the scarcity of experienced miners, it has been necessary, to a great extent, to teach and qualify the men for the work required of them. This serious shortage, with the increased cost of all materials, has upset altogether the pre-war standard of working costs, and has resulted in the closing down of many mines. A smaller tonnage of ore was opened up than in 1918. This was partly due to the failure, so far, to open up, on the 1850-ft. and lower levels, the ore-shoot which was developed with such satisfactory results in the earlier part of the year on the 1600-ft. level. Again, some delay in development operations was caused by the heaviness of the ground, which made it necessary to take special steps to strengthen the shaft. However, a new level has been opened up at 2750 ft. where the north foot-wall drift shows, up to the present, 70 ft. of good ore over a width of 62 in. On the 1500-ft. level the south drift has been extended to intersect what is known as the No. 2 south ore-shoot. This orebody has been cut, and so far is showing good results. A considerable amount of what might be called 'prospective' development work has been carried out in various parts of the mine with promising results. The operations since the close of the year have been equally promising.

IDaho

Coeur d'Alene.—The Haynes mill, at the mouth of Pine creek, is handling about 60 tons of ore per day and is shipping five cars of concentrate per month to the Bunker Hill smelter at Kellogg. The feed averages about 5% and the product 30% lead, and 24 oz. silver per ton.

The Ajax Mining Co. has picked up the vein again on the 750-ft. level, according to report. The vein is narrow, but promising.—The Willow Creek Mining Co., whose property is south of the Carney and east of the Carbonate Hill, near Mullan, has resumed operations. The tunnel has a length of 170 ft. and will be driven an equal distance farther to tap the vein which indicates lead-silver ore at the surface.

The Nabob Consolidated Mining Co., in the Pine Creek district, has accumulated two carloads more in the bins at the mill, according to B. N. Sharp, superintendent. The concentrate averages about 50% lead and 20 oz. silver per ton, and the net value is about \$70 per ton. The tailing contains 0.7% lead. This is an average of the tailing since the mill was started. The orebody struck recently on the Denver tunnel level has a width of four feet at the face, as compared with one foot at a point 15 ft. back in the drift.

Elmore County.—Gold ore seven feet wide has been found by the Gold Mines Co. on its property, near Mountain Home, according to report. The shoot was opened at a depth of 350 ft. by a tunnel driven more than 700 ft., and contains \$10 to \$25 per ton. A contract has been let for drifting on the vein. The ore can be dressed on the property by amal-

gamation and cyanide. The building of a mill will be considered when the development has proceeded further.

Hailey.—Galena ore in a vein six inches to two feet wide has been cut in the Queen of the Hills mine, one mile from Bellevue. A sample contained 2% lead and was rich in silver. High-grade ore found in other parts of the mine usually contains 150 to 200 oz. silver per ton.

Lewiston.—Free-milling ore has been found in a large vein in the Swastika group of mines six miles south and east of Dixie. It is said that several assays run \$60 per ton and one goes \$100. Eastern capital has been developing the property for several years. Two shifts are at work.

NEVADA

Austin.—Shipments have begun from the 200-ft. level of the Austin Dakota to a Utah smelter. The south-east cross-cut from the 300-ft. level has intersected a vein believed to be the Dalton. About 12 in. of shipping ore is opened, together with a wide face of milling ore.—Operations have been resumed on the Cahill Lode group, in the Birch Creek district, with one shift. The shaft has passed through the limestone and entered basalt. Within 30 ft. Jack Cahill, the manager, expects to encounter the Cahill lode.—The Nevada Birch Creek Co. is sacking ore from the upper tunnel workings and will ship as soon as the roads are in shape for heavy traffic. The raise from the lower tunnel is entering a formation with stringers of quartz.—The Birch Creek Mining Co. has purchased a 15-hp. gasoline hoist preliminary to sinking a 200-ft. shaft on the Bradley group. F. L. Andregg is superintendent.

Mina.—Construction of a 45-ton cyanide mill has begun at the Olympic gold mine, near Gunco. The plant will replace the 100-ton mill destroyed by fire on November 21, and is said to represent an expenditure of approximately \$100,000. The Olympic Mines Co. recently purchased the nearby Loo mine and will supply the mill with ore from both properties.

Pioche.—Negotiations are proceeding for re-opening of the Mazeppa property under new management. Development consists of an 825-ft. shaft and lateral workings, with the orebody showing consistent strength in the deeper workings. The main orebody, opened to a vertical depth of 800 ft. from the surface, yielded over \$1,000,000 in pioneer days of Pioche. The ore is largely silver-lead. It is probable that the new work will be carried on from the Meadow Valley shaft. Large reserves of medium-grade ore are said to be blocked out in old workings.

Wonder.—Consolidation of the Dickey V., Spider-Wasp, Golconda, Bald Eagle, and Vulture properties has been effected by George A. Manning and associates of New York. It is stated that a mill will be erected during the summer, and that development of the merged properties will be pushed.

MEXICO

Pachuca.—Official advices state that the deaths resulting from the fire in the El Bordo mine, recently acquired by the Santa Gertrudis company, numbered 75 as against the first report of 136 missing. The fire occurred between the 305 and 415-ft. levels on March 10, and the extent of the damage

is not yet determined. The casualties were among the natives and none of the supervising staff was injured.

FELLOWSHIPS IN METALLURGY AT THE UTAH SCHOOL OF MINES AND ENGINEERING

Invitation has been extended to qualified men to make application for fellowships in the Department of Metallurgical Research during the year 1920-1921. This department is maintained in connection with the Utah Station of the United States Bureau of Mines. By agreement the work of this department is under the immediate supervision of metallurgists of the Bureau, assigned to duty at this station. During the coming year, 1920-1921, the problems to be continued are the following:

(1) General ore-dressing problems, (2) special problems bearing on the flotation treatment of ores, (3) volatilization process and its application to gold-silver ores, (4) volatilization process and its application to lead ores, (5) volatilization process and its application to copper ores, (6) hydro-metallurgy of zinc, and (7) oil-shale investigations.

The openings announced afford an excellent opportunity for qualified young men to become experts in the fields of mining and metallurgy and to prepare themselves for special highly technical work in these fields. Those who receive this training have been, and are, in great demand at remunerative salaries. There are several fellowships to be awarded, each having an annual value of \$720. These fellowships are open to college graduates who have had a good training in chemistry and metallurgy and applications for them will be received up to May 15, 1920. Applicants should send a copy of their records from the registrar's office of the college where they have, or will be, graduated and the names and addresses of at least three references who know their character, ability, and attainments.

Holders of these fellowships will be subject to the rules governing employees of the United States Bureau of Mines and will report for duty about July 1, 1920. They must also register as students in the University of Utah and become candidates for the degree of Master of Science in Metallurgy (unless this or an equivalent degree has been previously earned). Their class work will be directed by the heads of the departments of instruction and their laboratory work by metallurgists of the Bureau of Mines. Fellows are appointed for one year, but the appointment may be renewed. Fellows have no laboratory fees to pay. Applications should be addressed to Jos. F. Merrill, Director of the Utah State School of Mines and Engineering, Salt Lake City.

Obituary

William Weston died on March 30 at Denver, succumbing to an attack of pneumonia at the age of 76. He came to Colorado first in 1870, from London, on a hunting tour. Later he became general traveling agent for the Kansas Pacific Railroad, doing much to advertise Colorado. He was engaged in mining in various parts of the State, notably as advisor to David H. Moffat. He was a familiar and respected figure in Denver mining circles and will be mourned by many old friends.

Harry Haskell Small, sales manager for the Goodman Manufacturing Co., Chicago, died on April 4, after a brief illness. He was born October 7, 1862, at Portland, Maine. His public-school education was supplemented by preparatory work at Phillips Exeter Academy and by technical training at Worcester Polytechnic Institute. After association with other industries he came to the Goodman Manufacturing Co. in 1901, as manager of the contract department, from which position he was promoted to that of sales manager in 1912. He had a wide acquaintance throughout the mining industry and was held in high esteem by all who knew him.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Albert C. Burrage is at Salt Lake City.

L. W. Storm, of Seattle, is in San Francisco.

Harry J. Wolf, of New York, is in Arizona.

Jay P. Graves has returned from Pasadena to Spokane.

D. D. Moffat was recently at McGill, Nevada, on an inspection trip to the Nevada Con. mill.

Louis S. Cates, manager for the Utah Copper Co., was in San Francisco recently for a few days.

Walter Karri-Davies has gone from Victoria, B. C., to London. He expects to return shortly.

George T. Jackson, manager for the Alaska Gold Mines Co., has returned from San Francisco to Juneau.

C. Erb Wnensch has gone to Salvador, where he will engage in making geologic investigations for three months.

Charles H. White is on a motor tour to the Grand Canyon, proceeding thence to Globe, Arizona, on professional work.

Frederick Cowans, general manager for the Utah Consolidated Mining Co., of Bingham, is in California on a vacation.

C. F. Kelley, of the Anaconda Copper Co., was at Soda Springs, Idaho, recently, inspecting phosphate deposits in that vicinity.

John T. Reid has left New York for his home at Lovelock, Nevada, where he will spend the summer, returning to New York next fall.

L. V. Cummins passed through San Francisco last week on his way from Yokohama to New York. He will return to Japan on June 30.

Walter Fitch, president of the Chief Consolidated Mining Co., has returned to his home at Eureka, Utah, after a vacation in southern California.

F. A. Goodale has returned from Queensland, where he has been examining alluvial deposits, and is now with the You Bet Mining Co., at Colfax, California.

P. J. Mackintosh, general manager for the Three Kings Mining Co., at Park City, Utah, has returned to his headquarters at Salt Lake City after a trip to Pittsburgh.

A. L. Gholz, superintendent of the contract drilling department for the E. J. Longyear Co., passed through San Francisco on his way from Minneapolis to Los Angeles and Arizona.

Clarence W. Burton, of Salt Lake City, has accepted the position of resident engineer for the Ontario Silver, Keystone, and Naildriver mining companies. He will make his headquarters at Park City, Utah.

S. Paul Lindau has resigned his position with the St. Joseph Lead Co., at Herculaneum, Missouri, to accept a position as assistant superintendent for the Compania Metalurgica Mexicana, at San Luis Potosi, Mexico.

G. P. Bartholomew and **John C. Emison** have been elected directors of the American Smelting & Refining Co., to succeed **Karl Eilers** and **Leopold Frederick**, who have retired. Mr. Emison has recently become associated with the company, after 15 years service with the National City Bank of New York.

O. B. Smith, a graduate of the 'Tech' ('97), has resigned as assistant to the managing director and head of the exploration department of the Granby Consolidated Mining, Smelting & Power Co. He has been with this company for 21 years. From 1908 to 1919 he was general superintendent of the mines. It was on his joint report with **H. J. C. MacDonald** that the company acquired the Hidden Creek property at Anox. His resignation is prompted by ill health.

EASTERN METAL MARKET

(By wire from New York)

April 19—Copper is inactive but steady. Lead is lifeless and lower. Zinc is dull and easier.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 990 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of a dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

TARIFF ON TUNGSTEN

The following is from the report of the Committee of Finance on H.R. 4437, providing for a tariff on tungsten:

Tungsten is a vitally important war metal. It is equally important in our industrial peace program. Tungsten is the only known element which forms an alloy with steel, giving to this steel the property of retaining its temper at extremely high temperatures. This property, together with its hardness, makes possible the manufacture of tools for drilling, cutting, and finishing steel products. Those tools are operated at such high speed that one machinist and one lathe can do as much as five machinists and five lathes equipped with carbon-steel tools. Quantity production is dependent on high-speed tungsten steel.

Prior to the War Germany controlled the tungsten refining industry and very little tungsten was refined in the United States. During the War the tungsten industry was fully established and the United States became the leading nation in the manufacture of tungsten products.

The mining of tungsten in the United States was greatly stimulated during the War and the production, in 1917, reached 6144 tons of 60% concentrate. The evidence showed that the normal requirements of this country were between 5000 and 7500 tons of 60% concentrate per year. The annual production from the equipped mines that can be operated under the proposed duty was demonstrated to be from 4000 to 1500 tons per year. It is claimed through the stabilization of price and stimulus of the duty, that this production can gradually be increased until our entire domestic requirements will be supplied. During that period of development a substantial revenue would be received from importations of ore.

The destructive competition which American producers are helpless to meet comes from the ores of Asia. The costs of domestic production were proved from certified statements to average \$13 per unit. The foreign costs were shown to be from \$2 to \$4 per unit; and foreign ores are being sold in New York at from \$3 to \$7.50 per unit. Large quantities, aggregating about 50,000 units per annum, are being imported, duty free, and none is being produced now in the United States. The difference in costs are not due alone to the discrepancy in high wages paid our American miners (from \$4.65 to \$15.00 per day) and the pitiless hard Asiatic conditions (from 20c to 50c per day), but the physical character of the deposits is different. Most foreign ores are recovered from rich surface deposits, that require little or no equipment, while American ores are recovered from veins or beds of hard rock. Expensive mine equipment is required and large costly mills are necessary, as the ore has to be crushed and concentrated to put it into a marketable product.

It has been shown that the tungsten mining industry is in a critical condition. Unless prompt action is taken it will be lost. Every mine in the United States is closed down, and without the duty asked for cannot reopen. The industry which has proved of such vital importance during the War will fall in decay so it cannot be rehabilitated and the country will be left to the mercy of Asiatic production to supply the material as necessary in our industrial peace program as it is essential in war.

From the showing made it is perfectly evident that this industry should be protected. Without a healthy tungsten industry the United States will be completely at the mercy of hostile nations, which could instantly cut off supplies. The production of war material would be paralyzed.

Eastern Metal Market

New York, April 14.

The railroad strike in the Central States and in the East is a predominating factor, making for hesitancy in all markets. Movement of all metals is held up. The markets are therefore quiet but steady.

Copper buying has fallen off but quotations of leading producers are firm. The outside market is lower.

The tin market is quiet following a heavy buying movement last week.

Lead prices in the outside market have advanced and demand is larger than the supply. The zinc market is quiet and prices are easier.

Quotations for antimony are lower.

IRON AND STEEL

The railroad strike has reduced activity in the steel industry to nearly half. Should the trouble last a few days longer nearly all the steel plants and rolling-mills will be closed almost completely. Many plants are operating only on stocks of fuel and raw materials, but no finished products can be shipped. The trade expects that resumption will be a straggling process, with shut-downs in one section and work resumed in others. The Chicago district was hit the hardest.

A feature of recent operations is the high steel-ingot output in March, which was at the rate of more than 145,000 tons per day, or 45,000,000 tons per year; the heaviest year, 1917, showed 43,619,000 tons.

COPPER

The heavy buying movement of late March and early April has subsided and demand now is light. This has been intensified by the serious railroad situation. Lighter demand, however, was to be expected following heavy purchases, as probably many large consumers are covered for April-May and perhaps second-quarter needs. The large producers are firmly quoting at 19.25c., New York, for electrolytic copper for April-May delivery with a premium for June and are not inclined to quote for the third quarter. Lake copper is unchanged at 19.50c., New York. There is also an outside or secondary market in which copper, from small producers and dealers, is obtainable at as low as 18.50c., New York, for delivery during second quarter. Foreign demand is also light under present conditions. Germany has, however, in the past purchased a surprisingly large amount as judged by her financial position and other considerations.

TIN

A shortage of metal, as mentioned in last week's letter, for late April and early May consumption as a result of the small quantity of tin afloat and in stock and landing on March 31, appears almost certain in view of March statistics published last week. This situation was sensed by buyers who at once realized its seriousness and entered the market. As a result there was heavy buying on Thursday and Friday, April 8 and 9, spot Straits selling on Thursday at a range of 61.25 to 61.50c., and on Friday at a range of 61.50 to 62c., New York. This buying was for prompt delivery and for metal to arrive in April and May. The demand became so heavy that the buying broadened into future shipments. The purchasing was participated in mostly by large consumers and to some extent by dealers. The buying and selling were both of a general nature. The small shipments from the East had set the trade to thinking. Thus far this week the market has been quiet and the buying light, due partly to an advance in London of £13 per ton on Monday and £1 yesterday, bringing the price of spot Straits yesterday to £346 5s. per ton. The market was quoted yesterday at 63.25c., New York, for spot Straits. This has temporarily stopped buying

by consumers who still adhere to a policy of buying on the dips and abstaining on the bulges. Should London recede, another spurt of buying is anticipated here. The arrivals thus far this month have been only 934 tons with 3916 tons reported afloat.

LEAD

The tendency to a return of strength noted last week has been intensified. The market is stronger and prices are higher in the outside market. They have even reached a parity with those of the leading interest so that lead for early shipment is quoted at 9.25c., New York, or 9c., St. Louis, in both markets. It is impossible to buy the metal for early delivery at less than 9.25c., New York, and early shipment has sold at as high as 9.37c.; for June at 9.50c.

ZINC

The market has receded slightly owing to two causes. One is the railroad strike, which has affected freight from the Atlantic as far west as St. Louis, where zinc originates, and the other is the selling in this market by British traders of metal bought for export but which can be sold to advantage here and re-purchased at a lower level in London, the market there having receded decidedly recently. Prime Western for early and second quarter delivery is quoted at 8.40c., St. Louis, or 8.75c., New York.

ANTIMONY

Quietness continues to pervade the market and demand has slackened. The better grades are obtainable at around 11c. per pound, New York, duty paid, in wholesale lots for early delivery.

ALUMINUM

Wholesale quantities, virgin metal, 98 to 99% pure, are obtainable for early delivery at 33c., from the leading producers, and at 31c. per pound from outside sellers.

ORES

Tungsten: Buyers are keenly interested in the tariff development. Confidence is growing that the bill will be passed, one reason offered being that votes for a tariff on dyes will be needed and can be exchanged for votes for the tungsten tariff. The market is firmer if anything. Ore prices are said to be at a minimum of \$7 per unit for low-grade material.

Ferro-tungsten is quoted at 85c. to \$1.15 per pound of contained tungsten. There is less tendency to import the British alloy because higher exchange rates have caused an advance in the cost of the British product.

Molybdenum: There is no business reported and quotations are unchanged and nominal at 75c. per pound of MoS₂ in regular concentrates.

Manganese: Quotations are unchanged at 80c. per unit for high-grade ore, seaboard, for early delivery and possibly as low as 65c. per unit for later delivery. Some foreign ore is available at these figures but no sales were recorded during the past week.

Manganese-Iron Alloys: The ferro-manganese market is strong with demand for early delivery more active. Prices are unchanged at \$225 to \$250, delivered, for prompt and early delivery at which some sales are recorded of both British and American alloy, but in limited quantities. The American product thus sold has been mostly electric alloy. The quotation for last half continues \$200, delivered, for the American alloy, with some British available at \$195, seaboard, for shipment during and after August. **Spiegeleisen** is quoted from \$64 to \$75, furnace, by two different makers, but some alloy, 18 to 22%, evidently re-sale, has sold at \$58, furnace.

Company Reports

JIM BUTLER TONOPAH MINING CO.

Report for the year ended December 31, 1919.

Property: mine and mill at Tonopah, Nevada.

Operating Officials: Frederick Bradshaw, general superintendent; L. R. Robins, mining engineer.

Financial Statement: receipts from shipments of ore, \$104,664; miscellaneous income, \$12,705; total, \$117,369; operating cost, \$91,389; net loss on Belmont-Shawmut Mining Co., \$49,875, and on Belmont-Wagner Co., \$41,848.

Dividends: none in 1919; total to date, \$1,151,074.

Development: 1159 ft. of development work was performed in the Wandering Boy mine, but no orebodies of great size have been found. The small remaining ore-reserves are expected to produce only small profits.

Production: 5711 tons of ore was treated with an assay value of \$23.48 per ton. The net realization after deducting mining, transportation, and milling charges, was \$6.62 per ton.

YUKON GOLD COMPANY.

Report for the year ended December 31, 1919.

Property: 650 claims in the Yukon Territory, 24 claims in the Iditarod district, Alaska, and dredging-land in California; also lease near Murray, Idaho.

Operating Officials: O. B. Perry, general manager; E. E. McCarthy, resident manager in Yukon Territory.

Financial Statement: operating gain from the various properties was as follows: dredges at Dawson, \$182,511; hydraulic operations at Dawson, \$161,128; dredges in California, \$71,274; dredge at Murray, \$52,845; miscellaneous, \$41,131; total, \$508,890. Charge for depletion, \$303,963; depreciation, \$486,896; stock investments written off, \$653,156. Net deficit for the season, \$1,108,684.

Dividends: none in 1919; total to date, \$9,858,110.

Development: the exploitation of placer tin by dredging in the Federated Malay States is under way. Sufficient ground for three dredges has already been proved, and two dredges, together with a steam-turbine generator plant, are on the way to Malay.

Production: the value of the total production was \$1,699,632, the Dawson dredges producing 40% of the total.

OLD DOMINION COMPANY

Report for the year ended December 31, 1919.

Property: the company controls the Old Dominion Copper Mining & Smelting Co. and the United Globe Mines, with mines, mill, and smelter in the Globe district, Arizona.

Operating Officials: W. C. McBride, general manager; I. H. Barkdall, mine superintendent; H. H. Colley, smelter superintendent.

Financial Statement: income from sale of copper, silver, and gold, \$3,205,879; mining, treating, and refining expense, \$5,012,629; charge for depreciation, \$325,042; depletion, \$346,000; selling and general expense, \$83,074; interest, \$125,442. The company had \$4,214,775 of finished metals on hand on December 31, as compared with \$2,251,266 on January 1. Net loss, \$723,135.

Dividends: no dividends in 1919; total to date, \$14,405,260.

Development: 25,844 ft. of development work was accomplished. The development on the 17th and 18th levels in the western part of the mine was disappointing but did not definitely show that the continuation of orebodies will not yet be discovered.

Production: 50,188 tons of smelting ore, 200,304 tons of concentrating ore, and 3194 tons of converting ore, with an average copper content of 4.28%, produced 28,166,396 lb. of refined copper with 137,071 oz. silver and 5755 oz. gold.

The smelter was operated at an increased cost because of the small tonnage treated.

AMERICAN ZINC, LEAD & SMELTING CO.

Report for the year ended December 31, 1919.

Property: mines in the Joplin district, Missouri; smelting plants in Kansas and at Granby, Missouri. There are subsidiary companies in Tennessee, Wisconsin, Illinois, and Missouri.

Operating Officials: H. R. Young, manager of mines, C. B. Strachan, superintendent of the Tennessee mines.

Financial Statement: the consolidated balance-sheet, which includes the subsidiary companies, shows an operating loss of \$19,266 after allowing deductions for mining, manufacture, marketing, general and excess profits taxes, and interest. Miscellaneous profits were \$451,304, making a total profit of \$432,038. Surplus, December 31, 1918, was \$4,421,722, and December 31, 1919, was \$3,695,152.

Dividends: on the preferred stock, \$482,037 was paid; total to date, \$613,620.

Development: ore-reserves at the Mascot property at the end of the year materially exceeded those at the beginning. To meet the increasing demand for lead-free zinc oxide a new plant was started at Columbus, Ohio. The zinc-oxide plant at Hillsboro, the sulphuric-acid plant at East St. Louis, and the limestone plant at Mascot, Tennessee, were improved and added to.

UTAH CONSOLIDATED MINING CO.

Report for the year ended December 31, 1919.

Property: mine at Bingham, Utah.

Operating Officials: Frederick Cowans, general manager; A. S. Winther, superintendent.

Financial Statement: mining expenses, \$799,829; development, \$245,111; ore-testing, \$32,820. Total, \$1,077,759. Smelting charges, \$632,807; litigation, \$116,403. Proceeds from sale of products, \$1,971,631; miscellaneous deductions, \$168,539. Profit for the year, \$181,966.

Dividends: none during 1919. Total to date, \$12,810,000.

Development: 17,407 ft. of development and exploration work maintained the ore-reserves on a par with those at the beginning of the year. The newly opened ore is on the 1800 and 2000-ft. levels. The 2200-ft. level was opened. Laboratory experiments on flotation treatment of copper ore were confirmed by a mill-test on 2500 tons and plans were completed for a 1000-ton mill.

Production: 126,893 tons of copper ore and 45,377 tons of lead ore yielded 5,710,346 lb. of copper, 13,072,177 lb. of lead, 373,179 oz. of silver, and 10,548 oz. of gold.

SHATTUCK ARIZONA COPPER COMPANY

Report for the year ended December 31, 1919.

Property: mine and mill at Bisbee, Arizona.

Operating Officials: L. C. Shattuck, general manager; Arthur Houle, superintendent.

Financial Statement: gross value of production, \$1,017,359; miscellaneous receipts, \$52,339; cost of mining, refining, and marketing, \$1,054,656; administration, \$36,935. Loss, \$21,893. Depletion and depreciation \$164,606. Net loss, \$186,500. Surplus balance on December 31, \$557,671.

Dividends: during 1919, \$437,500. Total to date, \$7,612,500.

Development: this work was hampered by an underground fire, which necessitated the flooding of the mine below the 700-ft. level. The work of pumping the water is now completed. Rich copper ore has been found in ground south of the previously known ore-zone; 4244 ft. of this character of work was done.

Production: 22,011 tons of copper ore and 49,150 tons of lead ore were mined, from which 2,111,841 lb. of copper, 257,749 oz. of silver, 4,432,655 lb. of lead concentrate, and some gold were produced.

Book Reviews

Traverse Tables. Henry Louis and G. W. Caunt. Second edition. Pp. 123. Edward Arnold, London. For sale by Mining and Scientific Press. Price, \$2.

This is an ordinary book of traverse tables varying by minutes. There is also a discussion of platting and computing surveys by co-ordinates. The relatively small number of surveyors that use traverse tables in their work will find this book as good as any on the market.

Mechanical World Year Book for 1920. Pp. 328. Ill., index. Emmott & Co., Manchester, England.

The present edition of this useful handbook has been enlarged and revised, the greatest additions being in the divisions on water and hydraulic work and on heating and evaporating liquids. Other important additions are to the division on compressed air and to the screw-thread tables. While the book is not so complete as many of the American handbooks, the material included is well selected. Naturally the book is suited more to the needs of the British than the American engineer.

Mining Manual and Mining Year Book, 1920. Compiled by Walter R. Skinner. Pp. 332. Index. Walter R. Skinner and 'The Financial Times', London.

This is the thirty-fourth consecutive issue of this standard reference work on mines. The object of the book is to place before the mining industry facts and figures in such form as to enable those interested to see at a glance the condition and prospects of mining enterprises throughout the world. The number of companies dealt with in the 1920 volume is 1400. The figures are based on authoritative information, and the last balance-sheet of the companies dealt with is given. In the appendix is an alphabetical list of directors of mining companies, engineers, and managers, with their addresses and affiliations. There is also an up-to-date glossary of mining terms.

Manual of Cyanidation. By E. M. Hamilton. Pp. 278, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

The avowed purpose of the book is to give practical assistance to the designer, builder, or operator of a cyanide-plant. Purely theoretical considerations are largely kept in the background. Various phases of cyanide work are discussed more in detail than seems necessary for the metallurgist, the reason being a desire to make the book available for the use of students. The chapter headings show the scope of the treatise: Notes on the Chemistry of the Process; Testing and Analysis of Solutions; Sand Leaching; Slime Treatment; Milling in Cyanide Solution; Discrepancies Between Actual Recovery and Theoretical Extraction (3 chapters); Ores Presenting Special Difficulties; Precipitation; Cleaning-Up and Melting; Laboratory Experiments; Cost-Sheets and Plant Data; and Tables. While there is little new in the book the data are conveniently presented.

The Lathe, Bench-Work, and Work at the Forge. By Henry D. Burghardt. Pp. 318. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

The author is instructor in machine work in a high school in Jersey City, and the book is addressed primarily to the boy or man learning the trade. Thus the first chapter is devoted to a general discussion of the machinist's trade. Then the general features of the lathe are considered, followed by a discussion of cutting tools and speeds and of gauges and micrometers. The various operations of centring, facing,

chucking, and turning are then considered, as well as the cutting of tapers and of screw-threads. Three chapters are then devoted to the various aspects of bench-work. The chapter on forge-work is brief and is concerned entirely with babbitting, brazing, soldering, and the tempering of tools. An appendix contains a number of useful tables. The book is an excellent text and reference book for the apprentice machinist.

Microscopic Examination of the Ore Minerals. By W. Myron Davy and C. Mason Farnham. Pp. 150, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

The principal part of the book is a systematically arranged set of 'Determinative Tables' designed to enable the student to apply a standard set of tests to all the minerals present in a section under observation in a metallographic microscope. The classification is based upon the action of a few common reagents upon the minerals. The chapters deal with the following: Preparation of the specimen for examination; photo-micrography of polished sections; the use of the tables; and supplementary tests. The latter discussed the older methods of determinative mineralogy. The work has been confined to minerals of comparatively common occurrence, with the idea of avoiding unnecessary complication. The use of the reflecting microscope as a means for determining the identity of minerals is a development of the last 15 years, but it has received wide attention, and the present book, the authors of which have had the advantage of comparison with former works, is probably the best so far published.

Electric Furnaces in the Iron and Steel Industry. By W. Rodenhauser, J. Schoenawa, and C. H. Vom Baur. Third edition. Pp. 444. Ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$4.50.

The rapid progress being made in the electric-furnace industry is indicated by the fact that a third edition of this book has become necessary in less than three years from the date of the appearance of the second edition. The principal changes and additions relate to the field of practice, such as descriptions of the newer types of furnaces and the inclusion of considerable new cost and other operating data. The new edition follows the same general lines as the preceding ones. After a brief historical chapter tracing the early developments in the industry, the fundamental phenomena of electricity affecting the electric furnace are discussed. Arc-furnaces in general are then considered, after which are several chapters discussing, in turn, the Stassano, Heroult, Girod, and Rennerfelt furnaces. Similarly, a chapter is given to the induction-furnace, followed by chapters relating to the Kjellin and the Rochling-Rodenhauser furnaces. Then comes a chapter on electric-shaft furnaces, and one discussing various other arc and induction furnaces, including the Chapelet, Keller, Nathasius, Gin, Schneider-Creusot, Gronwall, Lindblad & Stalhane, Greaves-Etchells, Snyder, Greene, Hlorth, Moore, Booth-Hall, Vom Baur, and Ludlum types. This completes Part I. Part II begins by considering the materials of furnace construction, principally refractory linings. Then follows a general discussion of costs of operation, including considerable specific data on actual operation. The remainder of the book is devoted to the electro-metallurgy of iron and steel and treats, in turn, the electric smelting of iron ores and the use of the electric furnace for melting, for the refining of pig-iron, and for the production of ordinary and special-quality steel. This edition, like the preceding ones, ranks among the best treatises on the subject, and it will be needed by everyone engaged in the industry.

T. A. RICKARD, - - - Editor

MEASURES for giving proper effect to the War Minerals Relief act are still in hand. On page 639 we publish the text of the recommendations made by the Committee on Mines and Mining of the House of Representatives with a view to expediting the award to claimants. We shall revert to this subject next week.

STRIKES in 1919 are estimated to have caused a loss of \$723,478,000 in wages and a further industrial loss, not to labor, of \$1,266,357,000. This happened at a time when the wage-earners were receiving the highest payment and incurring the most extravagant expenditures. But the loss in money does not measure the damage; the damage done to democratic institutions and to the orderly progress of this republic is incalculable.

GOLD remains at a substantial premium in London, ranging at about 20%, but the South African mining companies have already been mulcted of some of their gains. The banking discount rate for telegraphic transfers on London from Johannesburg has been advanced to 6%, which absorbs about 7 shillings of the gold premium. The white miners have demanded, and have obtained, a raise in wages. It remains to be seen what toll the Union Government will take from the gold-producers.

BEFORE the services of our soldiers and sailors are compensated in a commercial way and their splendid response to duty degraded by measurement in dollars, it were well to recognize the obligation owing to those who, out of meagre savings, subscribed the money needed in the hour of national crisis. We remember that the people who bought Liberty bonds were told that these would never go below par, they were the most gilt-edged of all securities, they were as good as wheat; yet we note an advertisement in a street-car offering to lend \$46 on a \$50 bond, to be repaid at the rate of \$1 per month, which means that in a year the holder of the bond will lose \$4 on his principal and \$2 or more in interest, making him pay \$6 for a loan of \$46 on \$50 worth of Government credit.

SOME of our readers may have had difficulty, as we have had, in figuring the premium on gold in London as against dollar exchange. To them we venture to say that fine gold is valued at 84.95 shillings per ounce and the pound sterling at \$4.8665, so that when, as on April 1,

the exchange stood at \$3.93 and the price of gold in London at 105 shillings, the premium on gold was 19.09% when the premium on the dollar was \$19.24, which is near enough not to afford any margin for speculation in the selling of gold from this side the Atlantic. Another fact worth remembering is that silver quotations on the London market are made variously on 'standard', which means 925 fine, and on 'fine', which means the pure metal. The disparity between silver quotations in London and New York or San Francisco is due usually to comparing 'standard' there with 'fine' here. Moreover the British brokers quote 'spot' and 'forward', the latter allowing time for New York silver to reach London, this survival of an old custom being a reminder of the days when sellers in London were given a chance to make delivery on account of purchases in China.

THE occupation of Agua Prieta by the revolutionary forces under General P. Elias Calles has placed the mine operators of Sonora in an unpleasant predicament because they export their ore and bullion through the Mexican customs-house in that town. The collector for the Carranza government, Señor J. M. Alvarez Tostado, though dispossessed of his office, has informed the mine officials by means of advertisements in the newspapers of Douglas, Arizona, that he alone is authorized to receive the duty on shipments passing through Agua Prieta; he gives public warning that he will not recognize receipts issued by the revolutionary government, and that all payments will necessarily have to be made again. However, we understand that most of the mining companies are continuing their shipments, for which they are making settlement with the acting officials. What diplomatic representations will be necessary to persuade President Carranza and his astute advisers that the tax should not be paid a second time is a matter for guessing. Many miners have deserted the mines to join the ranks of the Calles army. This will doubtless be a pleasant diversion for them until such time as this latest revolt is ended.

FIRE is said to have destroyed the little settlement of Columbia in Tuolumne county, on April 24. This early Californian mining camp is one of many communities born during the romantic days of the first gold discoveries in the foothills of the Sierra. Gold was found there in March 1850 and a population of 6000 miners with 143 faro-banks soon enlivened this lovely spot amid the

pinewoods. At that exciting period Columbia had an ambition to become the capital of California; in late years it dwindled to a few score derelicts left by the receding tide of mining activity along that part of the Mother Lode. We remember, many years ago, stumbling upon a group of abandoned cabins in a quiet corner of Calaveras county. The only sounds were the murmur of a mountain rivulet and the hammering of a woodpecker. A couple of seedy-looking Chinese were ground-shuicing where once an eager community of hopeful diggers had sought their fortune. The name of the camp survived upon a weather-beaten post. 'El Dorado' it was called. *El hombre dorado*, the gilded man! The myth of the Venezuelan wilds, where Raleigh first heard of the Indian chief that was covered with gold. 'Eldorado' has become synonymous with romantic expectation, not in mining affairs alone; so does the high expectancy of youth end in the derelict purpose of old age.

QUOTATIONS for South African mining shares have risen greatly during the last six months on account of the higher price obtained in London for the gold from the mines. For example, in January the Crown Mines company made £60,000 on an estimated premium of 22½s. per ounce of gold. During the same month the New Modderfontein made £47,000 in the same way. The premium profit, as it is called, in a year should amount to £600,000 for the Crown Mines and £470,000 for the Modderfontein, these amounts representing two-thirds of the entire nominal capital of the one and rather more than a third of the capital of the other company. It is not surprising that it is being said in London that the price of gold affords a spice of speculation to share-dealing on the South African mining market such as previously was supposed to characterize only base-metal mining shares. Even slow-witted persons have begun to understand that gold mining, like any other form of mining, is a 'speculation', not an 'investment'. The farce of measuring the resources of a gold mine to a thousand tons of ore and of appraising the shares to a shilling will be abandoned even by the most impudent of so-called experts. With premium dividends larger than normal profits, as in the case of the decadent Crown Mines, the outlook for the Rand is gorgeous. Even the excess-profit tax will remove only a film of gilt from the gingerbread, which will remain substantial and savory. The Rand was entitled to a bit of good luck and we are glad it has come at last.

HEARING of the case against the Minerals Separation company is in progress before the Federal Trade Commission. It is stated that Mr. John Ballot, the chairman of the company, admitted that the purpose of incorporating the American subsidiary company just before the United States entered the War was to gain the advantage of American law in enforcing license agreements upon American owners of mines. He admitted that about 500 American mining companies have been marked by him and his associates as infringers and that heretofore they have not been sued because of the desire not to in-

terfere with the production of the metals needed by the Allies. He emphasized the fact that the parent English company retained at least a 50% interest in the American subsidiary. At a later stage, on April 9, he defied the Commission and refused to answer questions regarding the amount of income received annually from American mining companies; and when directed by the Examiner to answer the question, he refused to do so until the Federal Courts shall have passed on the matter.

The Gold Bounty

On another page we publish the text of the bill introduced by Mr. Louis T. McFadden, of Pennsylvania, on March 22 in the House of Representatives. The purpose of this bill (H. R. 13201) is to protect the gold reserve of the United States from industrial depletion, in accordance with a resolution adopted unanimously by the American Bankers Association on October 2, 1919. Many proposals have been suggested, and have undergone careful scrutiny, with a view to accomplishing the desired result without disturbing the monetary system of the country. The McFadden bill is the outcome of an earnest effort on the part of conservative financiers, represented by the Bankers Association, and of the miners of gold, represented by the American Mining Congress, to arrive at a solution of the pressing problem. The Bill provides for an excise of \$10 per ounce on all gold used in manufactures or for other non-monetary purposes, the proceeds of this tax to be set aside for paying a bonus of \$10 on all new gold, that is, gold freshly mined. The jewelers, dentists, and other users of gold as a commodity will still be able to obtain all the metal they need at its monetary price of \$20.67 per ounce, but a tax of \$10 per ounce will be collectable on gold sold in manufactured form, not on bullion, which remains at its normal price, thereby maintaining a free gold market in the United States. The miner, on the other hand, will obtain a part of the enhancement of value that gold has undergone as a commodity, and by the receipt of a bonus of \$10 per ounce he will be encouraged to increase his production of the metal upon which our credit structure is based. It might seem more practicable to prohibit further sales of gold to the trade, but that would incite the destruction of gold coin, there being no law in the United States prohibiting the melting of coins. In 1919, it is estimated, \$8,000,000 of gold coin was melted for manufacturing purposes. In that year the gold furnished for use in manufactures and the arts in the United States was valued at \$80,337,600, as compared with the \$58,488,800 produced by the mines of the country; so that apparently \$21,848,800 more was consumed than was produced. However, the sale of old gold, in the form of plate and jewelry, to the Mint averages about \$8,500,000 per annum, rising to as much as \$19,517,345 in 1918, owing to the demand for charitable and patriotic purposes. The production of gold is decreasing, the consumption of gold in the arts and manufactures is increasing, so that in 1920 the loss to the monetary stock is expected to be at least \$25,000,000. The trend of the

jewelry trade is toward the larger production of machine-made articles, which necessitate heavier material on which to work. During the War a large number of goldsmiths migrated from Europe to New York, which is now the centre of this business, thereby intensifying the domestic consumption of gold in the arts. The demand for decorative dental work absorbs an increasing quantity of gold, and the extravagant tastes of this post-war period are stimulating a wasteful use of the metal that is needed for monetary purposes. Many causes, therefore, join in depleting the stock of metal. The miner is discouraged from any effort to find new orebodies by the continued rise in the cost of everything he uses, especially labor. In 1915 the output of gold in the United States was \$101,035,700; in 1919, it was only \$58,500,000; in 1920 it is likely to be less than \$50,000,000. Out of this total, only about 12% is obtained as a by-product in the winning of the other metals, so that the production of gold, unlike that of silver, gains but slightly from the expansion of base-metal mining. We recognize, of course, that the prosperity of an industry producing about \$50,000,000 worth of metal is of small consequence to a country having a foreign trade, for example, of 12 billion dollars, and we prefer therefore to discuss the McFadden bill not as a piece of class legislation but as a serious effort to serve the best interests of the country as a whole. The question arises, therefore, does the country need more gold? If it does, then it is as proper to stimulate our domestic production of gold, as of wheat, or pork, or sugar, or school-teachers. It is noteworthy that at the Seattle Mining Convention, Mr. Frank Vanderlip stated that an increase of our gold output would be of questionable benefit, because it would encourage the issue of more paper currency at a time when deflation was most needed in order to restore a normal ratio of prices at home and abroad. He pointed to the fact that the Federal Reserve banks are compelled by law to hold a reserve of gold not less than 40% against the notes that they put into actual circulation and therefore that an increase in their gold reserve would justify them legally in expanding their note-issue. However, an increase, say, of 50 millions in our gold production would only permit a possible increase of 20 millions in notes, which is a sum too small to affect the financial position of the country. The miner replies by pointing to the action of the British government in allowing gold to go to its logical premium in London and the consequent benefit not only to the mining industry under the British flag but also to the financial status of Great Britain itself in its dealings with its European neighbors. Normally the British dominions contribute 66% of the world's annual gold production; now that the Russian mines are idle or crippled and American production stifled by unfavorable economic conditions, it is probable that fully 80% of the world's new gold is being produced under the British flag. This will prove a source of great financial strength to Great Britain so long as the world's business is based upon the gold standard. It is, we believe, desirable, not in the interest of the gold miner alone, but in the national in-

terest, to stimulate our domestic production. If the McFadden bill will do it, it should be passed. Apparently, it will. We ask it not to help a special class of people or a special group of enterprises but to strengthen and establish the gold reserve upon which our monetary system is founded.

The Dolly Varden

The name of the heroine in 'Barnaby Rudge' has been given to a silver mine that is the talk of British Columbia. How it was discovered is related by Mr. A. J. T. Taylor in an article appearing in this issue. Mr. Taylor indeed tells the story of the enterprise from the start and explains how he, not a mining man, became involved in the legal complications that have made the Dolly Varden famous in the North-West. We can supplement his account of the affair with information from other sources. The first president of the Dolly Varden Mines Company, the late J. D. Hubbard, of Chicago, was vice-president of the Goldfield Consolidated, of Nevada, which company lent \$150,000 on a mortgage upon the Dolly Varden properties. The working capital proved insufficient, and apparently Mr. George Wingfield, the president of the Goldfield Consolidated, was unwilling to find more. Hence the troubles that ensued. In 1918 the building of the railroad, on which a profitable maintenance of output depended, was stopped and a quarrel arose with the contractors, the Taylor Engineering Company. Negotiations for the sale of the Dolly Varden to the Granby Consolidated Mining, Smelting & Power Company were terminated abruptly. This may be regarded as a misfortune, for the acquisition of the property by the Granby company would have been logical, having regard to the accessibility of its smelter at Anyox and its undoubted ability to bring the Dolly Varden enterprise to fruition. Next enters the Temiskaming Mining Company, of Ontario, in the person of Mr. Joseph Errington, a director living in California. Mr. Errington is a mining engineer. In October 1918 Mr. Taylor came to him at the Vancouver hotel and invited him to become interested in a deal for the Dolly Varden. Mr. Taylor showed him the reports made by Messrs. Henry Krumb and Carl O. Lindberg for the Dolly Varden company and by Messrs. J. A. Baneroff and E. J. Conway for the Granby company. Mr. Taylor urged haste, because he was being threatened by his creditors, who proposed to attach both his engineering works and his private property. He promised Mr. Hubbard's concurrence in the proposed deal. The price was to be \$1,000,000, of which \$150,000 was to be cash for the payment of the Taylor Engineering Company's liabilities on account of wages, which were to be settled at a discount. The terms were telegraphed to Mr. John P. Bickell, president of the Temiskaming company at Cobalt, and to Mr. Hubbard at Chicago. The latter replied that the Wingfield mortgage on the Dolly Varden would have to be satisfied before any new deal could be ratified. This obstacle appears to have been overcome and in December 1918 the Temiskaming directors approved the ar-

rangement, but as soon as the first payment was placed on deposit at Vancouver the creditors of the Taylor Engineering Company increased their demands. Hubbard and Taylor could not agree upon the amount that Taylor was to receive, and the negotiations broke down, because no clear title could be given to the Temiskaming company. As last arranged the Temiskaming was to pay \$150,000 in cash, \$250,000 was to be secured by notes, and \$500,000 was to come from 50% of the net profit earned by the mine. We have reason to know that Messrs. Hubbard and Errington did not stipulate for a commission, as stated in the report of the legislative committee, but that when negotiations apparently had been satisfactorily concluded Mr. Hubbard's directors offered him \$25,000 for his trouble and expenses, whereupon the Temiskaming directors followed suit, voting a similar bonus to Mr. Errington. This was embodied in the contract and was subject to the mine proving profitable. The failure of the negotiations and the worries incidental to them affected the health of Mr. Hubbard. He died last summer. Then came the enactment by the legislature of British Columbia, in itself a most extraordinary interference with a private quarrel between citizens, excusable only on the ground that the railroad to the Dolly Varden was being built by the Taylor company under charter from the Provincial government. The Dolly Varden company, of course, has brought suit against both Mr. Taylor and the Government of British Columbia, and the issue will be left to the courts, because on April 11 the Federal Department of Justice at Ottawa refused to disallow the Dolly Varden Mines Railway Act of March 28, 1919.

It remains to say that we have seen the report made by Mr. C. D. Kaeding, in January 1919, for the Temiskaming company. Mr. Kaeding is manager for the Dome Mines Company at Porcupine and an engineer of high repute. The Dolly Varden mine had been diamond-drilled and sampled by previous appraisers, whose reports were available. Mr. Kaeding found 38,590 tons of 22-oz. ore in the Dolly Varden and 50,000 tons of 15-oz. ore in the Wolf property, making a total of 1,601,854 ounces of silver in reserve. He estimated the working cost at \$6.10 per ton, so that a profit of \$900,000 seemed assured. The natural market for this ore is the smelter at Anyox, which needs it to mix with the ore from the Hidden Creek mine of the Granby company. This company in June 1918 made an agreement to smelt Dolly Varden ore, up to 400 tons daily, at \$1.50 per ton, returning 95% of the gross silver contents. The silicious flux needed at Anyox is costing the Granby about \$3.50 per ton, and it carries no appreciable precious-metal contents, so that the function of the Dolly Varden in this respect is quite plain. It is estimated that quartz containing two ounces of silver per ton could be landed at the wharf for \$2 per ton. Another available market is at Tacoma, but it would be more natural to smelt and refine the Dolly Varden output in British Columbia itself. The silver occurs mostly as argentite, but also as proustite and native metal, with galena, zinc-blende, and rhodochrosite, in a quartzose shear-zone in andesite. The mine is full of

promise but it needs capital and experienced management. Mr. Taylor is to be complimented upon his courageous effort to develop the enterprise and we hope that he will succeed in so adjusting the conflicting interests that a well-organized company with plenty of money and skilful management will be enabled to pull the Dolly Varden out of its troubles, financial and legal, into a position of assured productiveness and prosperity.

The Strike at Butte

Operation of the mines at Butte is at a complete standstill in consequence of the strike called on April 18 by the Metal Mine Workers Union No. 800 of the I. W. W. It is 14 months since the last strike of underground workers, although the metal-trades craftsmen were out for three months last summer. Following their usual custom, the radicals first called the strike and then made known their demands through the columns of the 'Bulletin', a local newspaper devoted to the 'interests' of the workingman. These demands include the release of 'class-war prisoners', the abolition of the 'rustling-card', the placing of two men on a machine, the establishment of a six-hour shift 'from collar to collar', and of a \$7-wage scale. All but the last of these are stock 'demands' and are not real issues. Naturally, the men want the rate of day's pay fixed as high as possible, but they would maintain the same attitude if \$7 were granted. Moreover, it is significant that practically all work at Butte has been done on contract or bonus for the past eight months and the average miner, with the exercise of reasonable diligence, has earned regularly \$7 to \$8, and many have done much better. It seems clear that this is simply another outbreak following the stereotyped I. W. W. formula, namely, the strike is the effective weapon in the 'class-war' struggle and as such it should be used wherever and whenever the miners are financially able to stop work for a time. Their grievance is a standing one. The unfortunate part is that while only a small proportion of the employees are actively in favor of the strike, the work of all ceases. One comparatively small group of radicals agitates at intervals, makes trouble habitually, calls strikes recurrently, and does the picketing. Non-citizens of Finnish, Irish, and Balkan extraction are prominent in this group. A second, and generally the largest, class is composed of those who are not in sympathy with the strike, but who recognize the cardinal principle that it is discredit to work on any job where some of the employees are on strike. They do not even consider the merits of the question involved. In a third group are those who, being satisfied, resent the attempt to interfere with their efforts to earn a livelihood and continue their work if they are given protection. However, even these men do not feel that their job is worth the risk of a broken head and the result is that a small minority of workers is able to force the suspension of all industry. A similar strike at Tonopah during the past week was settled promptly, the better element being in the majority.

DISCUSSION

Advice to Students

The Editor:

Sir—Mr. McDonald's summary of Mr. MacNaughton's address before the students of the Michigan College of Mines, together with the editorial comment thereon, appearing in your issue of April 17, are full of interest to any of us that went through the mill of a technical school, whether we came out chaff or something else.

Without the full text of Mr. MacNaughton's address it is impossible to determine just what he meant by specialization. To take his own illustration, however, I do not believe that his brass-bed manufacturer confined his studies to 'bed-ology' while he was in college. I am inclined rather to believe he mastered the fundamentals of metallurgy (perhaps specializing on brass-foundry practice in his senior year), and that he studied economics, psychology, interior decorating, and many other subjects. I further believe that after leaving college he continued to keep track of the progress being made along all of these lines, irrespective of whether or not he could see any immediate definite connection with the subject of beds, and that if world conditions should alter so as to destroy the demand for brass-beds, he would have foreseen such a change long enough to convert his factory to making iron beds, or, possibly even something else than beds, before the bottom dropped out of the market for his former product. If he really thought of nothing but beds, while he might have been a good man for a subordinate position, he must inevitably have failed at the head of the industry.

Abandoning the parable, however, the specialization that, I believe, has been, and is, an evil in our engineering colleges, is largely due to the impatience of many an undergraduate with anything that does not seem to be connected directly with getting a job when he leaves college. If he only realized it, not only is a certain amount of the 'humanities' just as essential as the more technical subjects to his attaining the greater usefulness as an engineer, but also he can be by no means sure that even the specialized technical subjects will prove to be of practical value to him. The undergraduate cannot read the future any more than the rest of us. Every engineer knows men that, educated in one branch of engineering, practised it for only a short time or not at all, and subsequently attained success in some other branch or in some calling only indirectly related to engineering. Yet all of these men were helped by study of the cultural subjects, or would have been if they had had it.

This same 'economic urge' is also a contributing factor

in the desire for such positions as chemist or surveyor, too often, as you have pointed out, 'blind-alley jobs'. It is true that 'a man must eat', but the recent graduate has seldom more than himself to support, and if he cannot do that anywhere, a college education was wasted on him. Furthermore, if the girl is worth while she will wait for him. Perhaps the changes of the past few years that have increased the pay of the unskilled and semi-skilled laborer a great deal and that of the minor technical employee little or none at all, will attract the young graduate to many 'jobs', such as tramping, where a man may often learn more than in a 'position' such as that of a chemist.

Probably the principal advantage of the jobs requiring hard muscular effort as compared with those where the hands can be kept fairly soft, is not the greater opportunities for acquiring technical information, although this often happens, so much as greater opportunities for learning how to handle men. Even when he has the best of intentions, the man of education who has always 'had everything' can seldom appreciate the 'rough-neck's' point of view. On the other hand, the self-made man that has fought his way up from the ranks too often has no consideration for the men he left behind him on the way. The best material for a real 'captain of industry' is to be found in the technically-trained man that has worked his way up through the hard jobs as well as the nominally easy ones. We shall need him in the future even more than in the past.

A. T. PARSONS.

San Francisco, April 21.

Combination Method of Mine Sampling

The Editor:

Sir—In your issue of February 28 Mr. Morton Weber gives details of the combination method of mine sampling. This is interesting. It is undoubtedly on the safe side to take some large samples and ship to a mill in order to arrive at a factor that can be employed to check the groove-samples taken in the mine. That it is almost always necessary to employ a sampling factor is my experience. Such a factor obtained by comparing large shipments with groove-samples is the best that can be obtained under the circumstances; the best under any circumstances is that obtained by comparing the results of the extraction of the orebody as a whole with the samples obtained during an examination. I have had occasion in several instances to utilize the combination method in both ways mentioned above, and possibly

some notes on these comparisons will be of interest.

Case I. A gold mine was sampled which had several veins, the assays ranging from \$1 to \$100 in gold per ton. The gangue was quartz. Some sulphides were present, possibly up to 5%. Samples during the examination were taken about 5 ft. apart, and in instances where it appeared advisable, samples were cut between the 5-ft. sections. No samples were rejected. During operations, the ore was sampled as it was being delivered in the mine-cars to the mill-bin. Samples were taken from the stamp-batteries, and finally the total contents were estimated by combining the bullion returns with the tailing. The average assay of car-samples was compared with gold in the bullion plus that in the tailing during a period of about six months. This checked almost exactly. The gold content as thus determined was about 10% lower than the results from the groove-samples. No new orebodies were encountered during the period of this run, therefore no adjustment of the original mine-sampling was necessary.

Case II. Groove-samples and samples taken by drilling holes in a hard sulphide with stoping machines were compared with a large number of car-samples. The range of assay was between 5 and 50 oz. silver. The groove-samples assayed 25% more than the car-samples. These, over a period of one year, checked closely with the smelter liquidations.

Case III. Investigation was made of a copper deposit where the assay of the ore from the mine fell considerably below the smelter returns. The ore was a hard cupriferous pyrite, occurring as lenses in schist, and, as estimated from groove-samples, was supposed to assay about 3.0% copper. The ore passed through a crusher, then a trommel with holes of $\frac{1}{2}$ in. diam., the fine going to the dump as reject, the coarse going to a sorting-belt, where waste, low-grade copper, and shipping-grade products were made. All of these products were sampled and weights determined for two months. The groove-samples were found to be more than 30% higher than the returns from the ore shipped to the smelter, after having made proper allowance for the waste products sorted out.

Case IV. A copper mine was being worked in which there was supposed to be a certain tonnage of 4% copper ore, as estimated from the assay-map. This ore was rather soft and contained oxides, carbonates, and sulphate of copper, as well as copper sulphide. The mine was re-sampled, and the assays checked within about 5% of the first sampling. The ore was mined carefully and as shipped assayed 4% copper, but only after sorting out 30% of material assaying about 1% copper.

Case V. Some dumps containing several hundred thousand tons of silver were sampled by sinking pits, and cutting down the pit samples in sections of 5 ft. each. The entire rejects were also sent to a smelter sampling-mill, the comparative results in ounces of silver being as follows:

	Dump A	Dump B	Dump C	Dump D	Dump E
	oz.	oz.	oz.	oz.	oz.
Quartered sample -	7.0	9.8	10.9	11.7	6.6
50 ton car sample -	7.0	7.2	10.1	10.4	5.5

The sampling factor on the above assays ranges from

0 to 26.5%, the average factor for the total tonnage in the dumps being 11.4%.

Case VI. A dump containing about 100,000 tons was sampled by sinking pits to the bottom of the dump, and taking samples from each 10-ft. section. Assays on the cut and quartered samples in comparison with assays on earload shipments were as 16 oz. silver to 12.5 oz. silver, the sampling factor in this case being 22%.

Case VII. Some dumps of silver ore containing approximately 60,000 tons may be mentioned where sampling of the dumps compared as follows, with assay results from liquidations from the shipments of these dumps to the smelters:

	Dump A	Dump B	Dump C	Dump D	Dump E
	oz.	oz.	oz.	oz.	oz.
Sample assays	14.6	15.5	17.8	12.2	12.3
Shipments	11.5	15.2	14.4	12.7	14.4

Case VIII. A mine was sampled and was estimated to contain 20,000 tons of ore. Before the mine was exhausted there was shipped some 90,000 tons. The assays of the first sampling; of the first shipments of 27,000 tons and of the entire shipments of 90,000 tons, were as follows:

	Gold	Silver	Lead	Insol.	Iron	Lime
	oz.	oz.	%	%	%	%
Mine sampling of 20,000 tons	6.53	5.4	14.2	21.1	24.1	4.3
Shipments, 27,000 tons	0.37	5.9	11.9	25.1	21.2	4.4
Shipments, 90,000 tons	0.31	6.9	9.8	23.7	23.5	4.9

In attempting to compare estimates derived from mine sampling with actual production, it is necessary to bear in mind that extensions of the original orebodies may have been followed and mined; also that increased or decreased prices for metals may have increased or decreased the quantity of ore mined with reference to the estimate. The 'porphyry coppers' are striking examples of this. It also sometimes happens that the ore becomes unavoidably diluted with waste or low-grade material, and this must be carefully considered in making comparisons.

S. F. SHAW.

Charcas, Mexico, April 18.

It is thought that the present Chinese mining laws requiring the Chinese majority ownership of mines are not likely to prove a serious embarrassment to American investors, as the Government will undoubtedly grant special charters to American corporations desiring to exploit Chinese mines provided the Chinese see that they will profit by such arrangements. The method most favored in such charters is for the Chinese to be given a minority interest in the corporations, paying for their stock with the property, while the actual cash received from American investors would be used for the development.

The chrome-ore deposits of the Smyrna Vilayet contain from 40 to 55% of chromic oxide. The annual production, which has fallen off, formerly reached 7000 to 10,000 tons, although proper economic management might produce 50,000 or more tons.

INCLUDING the production of Alsace-Lorraine, France now stands second in the amount of its iron and steel production, being exceeded only by the United States.

THE CAMP AT THE DOLLY VARDEN MINE

The Story of the Dolly Varden Mine

By A. J. T. TAYLOR

The Dolly Varden mine and the railway bearing the same name have been before the public since the fall of 1918, owing, first, to the dispute between the original owners, the Dolly Varden Mines Company of Chicago, and the Taylor Engineering Company of Vancouver, which resulted in special legislation at the last session of the Provincial Parliament of British Columbia and a transfer of the property from the Dolly Varden company first to the Taylor Engineering Company and from it to the present owner, the Taylor Mining Company Limited, and, second, to the fact that since the first of September 1919 the property has produced nearly five hundred thousand ounces of silver. The purpose of this article is to give a history of the property and a brief account of the vicissitudes that brought about the change of ownership.

The Dolly Varden is situated in the Portland Canal district of British Columbia, 18 miles from the Granby Consolidated Company's Hidden Creek mine and Anyox smelter. The claims themselves are 17 miles up the Kitsault river at the head of Alice Arm, Observatory Inlet, in the Skeena mining division, at an altitude of 1700 ft. The Dolly Varden railway parallels the Kitsault canyon from the mine to Alice Arm, and is the only means of local transport.

The discovery was made in 1914, on a projecting outcrop some 40 ft. wide, by a prospector, Ole Evindsen, now the proprietor of the Alice Arm hotel. Ole is not the pioneer prospector in the Alice Arm district. This distinction goes to Tom Stark, whose proud boast is that he "was the first white man in that country". The authentic history of the discovery of the property and the naming of the mine has been taken by me direct from Mr. Evindsen and is interesting enough to recount in full.

"I had heard talk of mineral wealth, so I left Prince Rupert and came up here with three other chaps in the

spring of 1912. We packed in grub and set out up the Kitsault river. None of us had been up there before, but we were hoping to find some good claims. One night just after we started, one of the chaps, Ole Pearson, had a dream. His uncle had died a few months before. Ole told us that his uncle had come to him in a dream the night before and had showed him a big white boulder and some rocks and said: 'You are going to find a big mine, which will make you rich so that you will not need to work for the rest of your life. You will go on until you find this boulder and these rocks and then you must stake the claim and the name you must give it is the Dolly Varden claim.' "

When Ole Pearson told his dream next morning his companions received it with amused interest and hope. Days passed as the little company fought their way up through the dangerous canyon without sight of mineral. Then two of the company went back for supplies, while Ole Evindsen and his companion Pearson struggled on.

"We took different paths about 75 yards apart. I took the higher ground to prospect," said Evindsen. "Then I saw in the bare andesite a streak of gray rock that looked like it carried silver. With my hammer I broke down the capping of the rock and saw that I had uncovered a vein that looked like very rich silver ore."

While Evindsen was examining his new find Ole Pearson let out a yell. "I've found the mine; I've found the mine," he cried in great excitement.

"I've found one too; stay where you are," called back Evindsen, who, as the more experienced prospector, finished his search before lowering himself down to where Pearson was waiting.

"Where's your mineral?" asked Evindsen, as he handed his own samples over to Pearson and looked around for signs of a vein or lode.

"I haven't found any mineral, but here's the boulder that my uncle showed me in my dream; and here's the

rocks and the river and the trees and everything exactly as my uncle showed me in my dream," insisted Pearson.

What was Evindsen's vein and Ole Pearson's boulder, the two prospectors concluded that the finger of Fate was clearly pointing their way. They started to stake their claim and make arrangements to record it. "Say, what is the name your uncle said we were to call the claim?" asked Evindsen. "Hanged if I can remember," admitted Ole Pearson at last, after vainly trying to enudge his brain. So far as Evindsen was concerned the name had slipped his memory. All that day and all the next day the two lone prospectors sat around trying to think up that elusive name, feeling that they could not afford to take chances on any other. At last hope came. The two companions hove in sight with the grub. Without disclosing their find Ole Evindsen put the fateful question: "What was the name of that claim that Ole Pearson's uncle told him?" A moment's pause and then the answer came: "It was the Dolly Varden."

Since then the original Dolly Varden property has been enlarged by later locations, so that there is now the Dolly Varden No. 1, the Dolly Varden No. 2, and so on, up to eight claims.

"How do you account for Ole Pearson getting that name 'Dolly Varden' in his dream?" I asked. Ole Evindsen pulled at his pipe and spoke reflectively. "I have tried to think that out," he said, "and I think I know where it came from. There was a book in the camp that we all used to take up and read now and then, and I see that it tells about Dolly Varden, the actress, in it. We all used to take a turn at the book and I think Ole Pearson must have read the name and it came back to him in his dream." He anticipated the next question by adding: "But the thing that puzzles me is that boulder and those rocks, just as Ole's uncle showed him in the dream. None of us had ever been up into that country before, and Ole says that everything is just exactly as he saw it in the dream. And she's turned out to be a mine just as the dream said," he added.

In 1914 R. B. McGinnis of San Francisco took a bond on the Dolly Varden group from Evindsen, and a similar bond on the Wolf group, two miles farther up the canyon, from the original locator, Donald W. Cameron. Early in 1916 Mr. McGinnis re-bonded both properties to the Dolly Varden Mines Company of Chicago, organized under the laws of the State of Delaware by the late J. D. Hubbard.

Mr. McGinnis explored the property by extensive tunneling and diamond-drilling, and thereupon exercised the option on both the Dolly Varden and the Wolf claims. At the outset the Dolly Varden company proposed to build a concentrator at the mine and to ship the concentrate over a trail that it proceeded to construct from the mine to Alice Arm. In the fall of 1916 the company found that the trail would not be adequate for its purposes, and in 1917 it applied to the Legislature for a charter to build a narrow-gauge railroad connecting the mine with tidewater. This was granted under the Dolly Varden Railway Act 1917, the terms of which required the company to complete a narrow-gauge

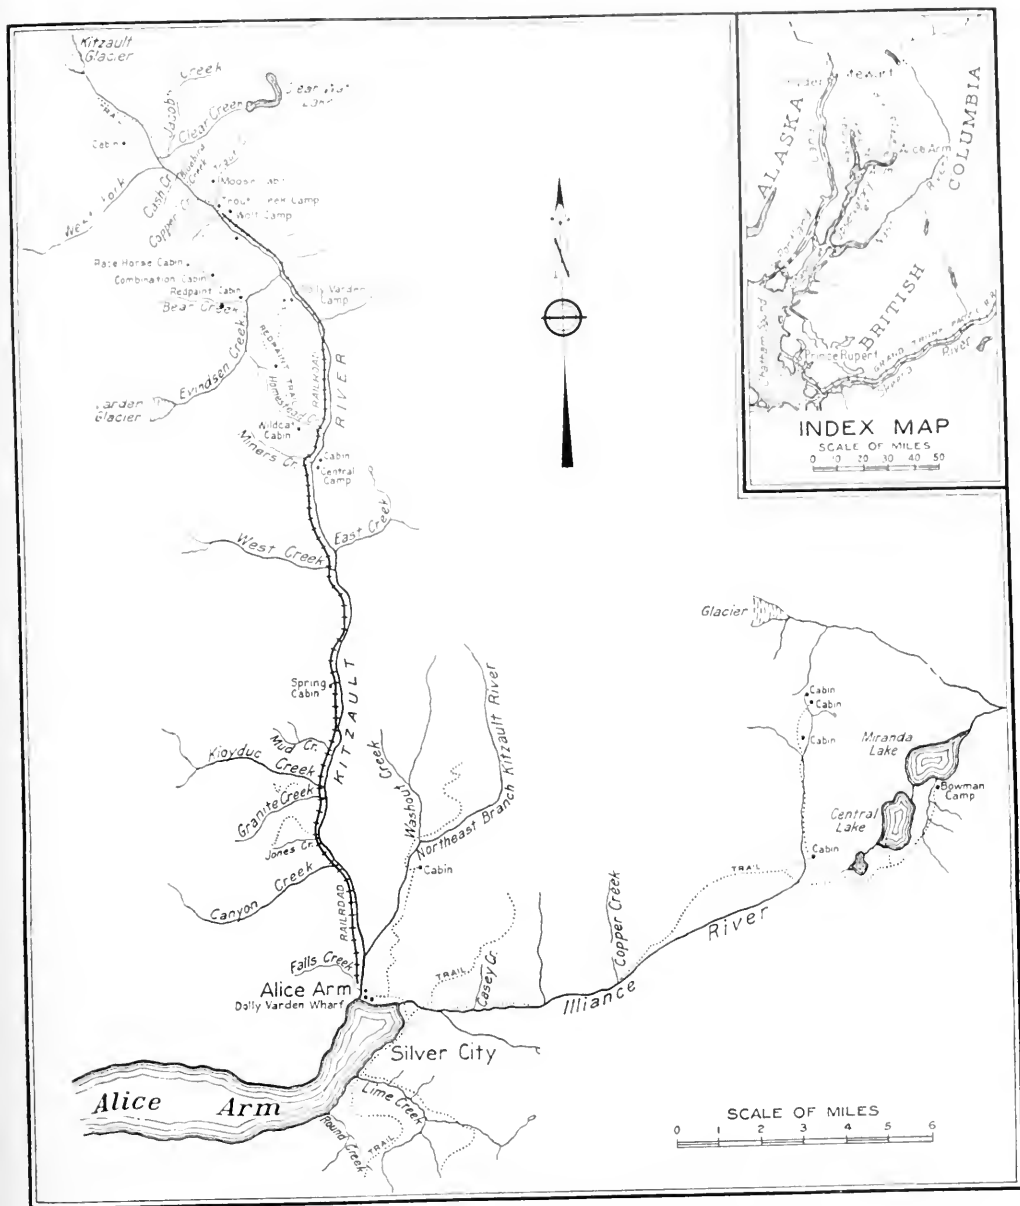

railway from Alice Arm to the Wolf mine by December 1918, in default of which the charter became null and void.

After the passage of the Act by the legislature of British Columbia, the company employed the Taylor Engineering Company to build the railway on the basis of cost plus a percentage, and in its desire for a speedy completion of the road the company desired the work to proceed without full surveys and profiles. Although the first few miles was easy, the construction at the upper end through the canyon of Kitsault river proved exceedingly difficult and expensive. Portions that the mining company's preliminary survey had shown to be grassy slopes proved to be moss-covered rock, while the last several miles of the road involved heavy rock-cutting and necessitated many bridges and trestles.

The close of 1917 found the railway uncompleted, owing to the difficulties of construction, labor troubles, and steamship strikes, the net result of which was that the road cost more than was anticipated and the Dolly Varden company was unable to realize on the ore that it had ready for shipment. In the spring of 1918 the Dolly Varden company entered into negotiations for the sale of the property to the Granby Consolidated Mining, Smelting & Power Co. The Taylor Engineering Company carried on the construction of the road for some time on its own capital, the details of which arrangement are set forth at length elsewhere in this article. Toward the end of the season of 1918 the Dolly Varden company terminated negotiations with the Granby company and denied all liability to the Taylor company for the work done. This unexpected turn of events forced the Taylor company to make an assignment for the benefit of its creditors in October 1918.

Much hardship ensued. Workmen with claims totaling \$150,000 were left unprovided, and members of the mine and engineering staff were threatened with violence. The creditors of the Taylor company made A. J. T. Taylor, president of that company, assignee in charge of its affairs, and Mr. Taylor in his efforts to avert a collapse of the undertakings of his company, and with the permission of Mr. Hubbard, interested the Temiskaming Mining Company of Ontario in a proposal to buy the property on terms that would have allowed all claimants to be paid in full. After these preliminary negotiations the Dolly Varden company entered into a contract with the Temiskaming company to sell the Dolly Varden and Wolf claims and railway, without departing from the stand that the Dolly Varden company had taken that it had no liability for the 1918 construction by the Taylor Engineering Company.

As the limit of time under the special Act of 1917 had expired, it became necessary for the Dolly Varden company to obtain from the Legislature an extension of time for construction of the railway in order to complete the sales contract with the Temiskaming company. The petition to the Legislature for a renewal of the railway charter was met by a cross petition from Mr. Taylor on behalf of the general creditors, asking that no renewal be granted except upon such terms as would protect all

MAP OF THE PORTLAND CANAL MINING DISTRICT, BRITISH COLUMBIA

the creditors. A special committee was appointed by John Oliver, the Premier of British Columbia, to hear all parties and report to the Legislature. The report was submitted by David Whiteside, chairman of the committee. He stated the matter in dispute thus:

"The dispute between these two companies comes before the Legislature in the form of a petition by the Dolly Varden Mines Company for an extension of the

time given to it under the 'Dolly Varden Mines Railway Act' of 1917 in which to complete the construction of the Dolly Varden Mines railroad, and a cross-petition by the Taylor Engineering Company, Limited, contractors for the construction of the road, praying that such a renewal of the Dolly Varden Mines railroad charter be not granted except upon such terms as shall constitute their claim for the unpaid balance of the charge for con-

struction, amounting to approximately \$462,500, as a lien upon the assets of the Dolly Varden Mines Company."

Describing the work on the railroad, the report proceeds to say:

"At the outset a light dinkey road was required, following the path of an existing pack-trail with capacity to haul out daily 30 tons of ore or concentrate. The Mining Company, in its desire to have the road completed and the mine operating before the close of the year 1917, desired that the work should proceed at once without the delay involved in having the usual surveys made and quantities calculated. The Taylor Engineering Company accepted the contract on a cost plus 10% basis. A written agreement that the work would not cost more than \$175,000 was given by the Taylor Engineering Company. This agreement, however, was, according to the evidence of Mr. Taylor, supplemented by a private verbal agreement whereby President Hubbard, of the Mining Company agreed to see that any excess above this figure up to an extra \$100,000 would be paid.

"After the road was commenced, labor difficulties, the increased cost of materials, improved standards of construction required, and unexpected difficulties in engineering resulted in an expenditure during the first season of over \$275,000 without the road being nearly completed. Mr. Hubbard observed the private agreement he had made to the extent of paying the contractor \$70,000 out of the extra cost of \$100,000, and work was stopped on the construction owing to lack of funds. Up to this point there is nothing in the relation of the two companies which calls for adjudication on the part of your committee.

"The present dispute arises out of the operations for the year 1918. Mr. Taylor was very anxious to complete the construction of the road. At the same time the shareholders of the Dolly Varden Mines Company, through Mr. Hubbard, were endeavoring to negotiate a sale of the property to the Granby Consolidated Mining, Smelting & Power Company. Mr. Hubbard represented to Mr. Taylor that the Dolly Varden company was unable to assume any financial responsibility for further work done upon the road, but assured Mr. Taylor that if he desired to go on at his own risk he would be fully paid in the event of the sale to the Granby company being made. In the event of the sale to the Granby company not being made, Mr. Hubbard stated that so long as the work was done to the satisfaction of the engineers of the Dolly Varden company, the Taylor company would have all its just claims paid and be given proper compensation for engineering and contractor's profits out of any subsequent disposition of the mine."

The letter from Mr. Hubbard to Mr. Taylor, dated May 14, 1918, is as follows:

Vancouver, B. C., May 14, 1918.

Gentlemen, I understand that you have proposed to Mr. Sylvester,* of the Granby Company, that the Taylor

Engineering Company should resume construction of the Dolly Varden railroad and carry it on pending the examination of the Dolly Varden properties by the Granby Company; that if the Granby Company should elect to exercise its option and purchase the Dolly Varden properties, the Granby Company would reimburse the Taylor Engineering Company for the outlay and make satisfactory arrangements with you for the completion of the road. I understand that Mr. Sylvester has indicated a willingness to accept your offer.

We are not concerned with any arrangement you may make with Mr. Sylvester in regard to the matter, provided the Granby does ultimately take the properties over; but in case they should not do so, it is obvious that your relations with the present owners of the property would become important and would require serious consideration.

You are already fully informed of the limitations and conditions affecting the ownership and the policy of the owners at this time, and this knowledge will enable you to readily understand the position which I am compelled to take.

The owners cannot and will not assume any liability whatsoever at this time. They will recognize neither a financial nor a moral responsibility to reimburse you, or to compensate you for this work in case the Granby Company does not buy the properties. They cannot and will not permit the properties to become subject to any lien for material, labor, or other charges. If the Taylor Engineering Company undertakes this work it will be necessary to have from them an instrument releasing the present owners from any financial or moral responsibility in the matter, and expressly waiving lien rights and protecting the property against such rights, not only as to the Taylor Engineering Company, but as to sub-contractors and material men.

As against this, you can rely upon the following facts and assurances: If the Granby Company should not exercise its option to take over the properties, it is obvious that the present owners will either have to re-organize, complete the railway, and operate the properties themselves, or dispose of them to some purchaser other than the Granby Company. In either event, and subject to the limitations stated below, I will personally assure you that any just claims you might have for the work done and materials furnished will be recognized and provided for either in case of re-organization or sale to others. Compensation for such claims would include not only a reimbursement, but proper compensation for engineering and contractor's profits. This assurance, however, presupposes that all work shall be done to the satisfaction of the owners, and will have to be approved by their engineers, who would be the sole judges as to whether and how far the work would be acceptable.

You may safely assume that the Dolly Varden properties with the railway constitute an asset of sufficient value to justify the assumption that any just claim you might have could and would be taken care of in the final 'work-out' of the proposition and in any event. A final payment of \$25,000 is due on October 1st next on the Wolf claims and the Goldfield Consolidated Mines Company loaned \$150,000 at 6%, which is due January 1, 1919, and for which the Goldfield Consolidated Company is entitled to a mortgage. This mortgage has not yet been recorded and its final form is yet to be agreed upon. I cannot personally guarantee it, but I have no doubt the payment on the Wolf claims will be made when due. In spite of the statement, the owners will not and cannot consider any arrangement which might create a lien upon the property, in case of foreclosure of the Goldfield mortgage, and failure to redeem by the present

*F. M. Sylvester, vice-president, and managing director at Vancouver.

owners, arrangements could and would be made whereby you could redeem from such foreclosure.

Yours truly,

J. D. HUBBARD.

The report proceeds to say:

"Relying upon the undertaking given in the latter paragraph of Mr. Hubbard's letter, the Taylor Engineering Company resumed construction-work in 1918. All parties were at that time expecting the sale to the Granby company to be carried out, and the work upon the road was done to conform to the requirements of the Granby company,[†] which required a roadbed of increased width with easier curves and capable of handling 400 tons of ore daily. This work was done, as the correspondence shows, under the supervision of R. B. McGinnis, resident engineer for the Dolly Varden company.

"The work was carried on in 1918 on the credit and capital of the Taylor company, which by the middle of July of that

year and to his engineer, Mr. McGinnis. On August 19, 1918, Mr. McGinnis wired to his chief, notifying him in effect that the Taylor company were at that date so far committed financially that they could not stop construction without financial ruin. On October 12 the Granby offer was refused. On October 22 construction

THE CAMP AT THE MINE

DIRECTORS AND OFFICERS OF THE COMPANY

year was at the end of its resources. When the offer of purchase was finally made by the Granby company, it was refused by the directors of the Dolly Varden company, owing to dissatisfaction over the proposed conditions of operation. The financial embarrassment of the Taylor company was well known to Mr. Hub-

bard and the Taylor Engineering Company assigned for the benefit of its creditors.

"Since assignment Mr. Taylor, in his efforts to enable the Dolly Varden company to obtain the money wherewith to pay off his claim, succeeded in bringing Mr. Hubbard and a representative of the Temiskaming Mining Company, of Cobalt, together. Mr. Taylor endeavored to effect a sale of the Dolly Varden properties to the Temiskaming company at a price of \$1,100,000, his services as an agent in the matter being given without charge. Since then, Mr. Hubbard, of the Dolly Varden company, and Mr. Errington, representing the Temiskaming company, have arranged for

the sale of the property to the Temiskaming company at a price of \$900,000, which includes a commission of \$50,000 to be divided between Messrs. Hubbard and Errington, this sale being conditional upon the renewal of the charter to the Dolly Varden railway.

"The sum of \$900,000 is insufficient to pay all parties without loss, and your committee understands that the proposal of the Dolly Varden company, which claims to have invested \$640,000 in the property, is that the char-

[†]We have abbreviated the names of the various companies, in order to save space and avoid needless repetition.—Editor.

ter for the railroad be extended on condition that they pay in full the wage-claims for the construction of the road, amounting to approximately \$150,000, and that the creditors of the Taylor company divide with them the losses on the mine and railroad project.

"It was urged by counsel for the Dolly Varden company that the president of his company, in his letter of May 14, 1918, repudiating all moral and financial liability to the contractors, had no authority to bind the company to any undertaking in the event of a sale to the Granby company not being carried out. Assuming this to be so, Mr. Hubbard having been allowed to assume the direction of the affairs of the Dolly Varden company, your committee considers that it would be unjust to allow the Dolly Varden Mines Company to divest itself of liability for the construction of the railway, especially when the company is engaged in marketing the very labor and material which was placed on their property as a result of the inducement held out by its president in his letter of May 14, 1918.

"The correspondence and evidence showed that the work in 1918 was carried out without excessive cost under the supervision of R. B. McGinnis as resident engineer of the Dolly Varden company, who reported to the president of his company on September 11, 1918 (six weeks before work stopped): 'The construction work on the road has been well done throughout, and the only complaint we could make is that they had spent more money on the upper end than we intended to at this time.' Mr. McGinnis also says in the same report to his president: 'If Granby takes the property, all right, and if we keep it we will have a good road, but have a heavier investment than was absolutely needed at the start. We could have changed the road later.'

"The evidence of the Government railway engineer who inspected the line was, however, that the road only met with the minimum requirements, was not extravagantly built, and that had it been less well built they would not have taken the responsibility of issuing the company a certificate to commence railroad operations. Your committee, therefore, being satisfied on the evidence that the work was properly performed and that the Taylor Engineering Company resumed operations in 1918 on the promises made in the letter of May 14, by J. D. Hubbard, president of the Dolly Varden company, that the Taylor company would be paid in full for its just claims, either from a sale to the Granby or 'sale to others', feels that the Taylor company is entitled to be paid in full for its 'just claims . . . for work done and materials furnished', to 'include not only a reimbursement, but proper compensation for engineering and contractor's profits', to adopt the language used by the president of the Dolly Varden company in its letter to the Taylor Engineering Company.

"Your committee points out that since the Dolly Varden company entered into the proposals to sell to the Temiskaming company for a price of \$900,000 an offer of \$1,100,000 for the property had been made by S. S. Taylor, on behalf of the creditors of the Taylor company. This offer is without the payment of commission to any-

one, and if carried into effect would enable all the creditors to be paid in full, and leave a sum larger by over \$50,000 for the shareholders of the Dolly Varden company than would be the case under the offer of the Temiskaming company.

"Your committee therefore recommends as follows:

(1) That a renewal of the charter of the Dolly Varden railway be granted to the Dolly Varden company upon compliance with the terms and conditions set out in the draft Bill annexed hereto.

(2) That if the Dolly Varden company and the Taylor company cannot agree upon the cost of construction of the railway during 1918, such cost shall be ascertained by reference to one of the Judges of the Supreme Court of British Columbia to be named by the Minister of Railways, and the cost so ascertained, together with 10% thereof added for contractor's profit, shall be declared a debt due from the Dolly Varden company to the Taylor Engineering Company.

(3) That the sum so ascertained to be due be constituted a lien or charge upon the said railway and upon all the assets of the Dolly Varden company . . . subject only to a mortgage for the sum of \$150,000 and interest in favor of Goldfield Consolidated, and to the balance of purchase-money due to Donald W. Cameron in respect of the Wolf group of mineral claims.

(4) That all wages due in respect of the construction of the railway in 1918 be paid by the Dolly Varden company within 14 days after the enactment of legislation giving effect to your committee's report.

(5) That the balance of the moneys due the Taylor company in respect of the construction of the said railway shall be paid within 30 days after the amount of the same has been so ascertained.

(6) That if the Dolly Varden company do not wish to assume the burden of the aforesaid payments to the Taylor Engineering Company, they must so notify the Minister of Railways within one week after the adoption of this report by the Legislature, in which event the Taylor company shall have the right, upon the terms and conditions hereinafter mentioned, to acquire from the Dolly Varden company the said railway and all the assets enumerated in the schedule attached to the said draft Bill, and the Dolly Varden company shall be entitled to receive from the Taylor company the amount of its investment in said assets in said schedule mentioned, such amount to be ascertained, in case of disagreement, in the same manner as the cost of construction of said railway.

(7) In the event of the Taylor company becoming entitled to acquire the said railway and other assets of the Dolly Varden company hereinbefore mentioned, the Taylor company shall pay off and discharge the said mortgage to the Goldfield Consolidated, or otherwise protect the Dolly Varden company against all claims and demands in respect of the same, and shall also pay off the balance of purchase-money due to said Cameron in respect of the Wolf group of claims mentioned in said schedule, and shall also within one week after the adoption of this report produce evidence satisfactory to the

THE RAILWAY NEAR ALICE ARM

Minister of Railways of the Taylor company's ability to complete the purchase of said assets from the Dolly Varden company.

(8) In the event of the Dolly Varden company deciding not to pay the cost of construction of the said railway, and in the event of the Taylor company acquiring and expecting the right to take over the said assets upon payment of the amount of said Dolly Varden company's investment in the same, the latter company shall be released from all claims and demands of the Taylor company in respect of the construction of said railway, and shall be entitled to be paid by the Taylor Engineering Company the amount of its investment so ascertained as aforesaid upon the terms set forth in the draft Bill submitted herewith."

Upon the Legislative Assembly receiving and adopting the report of the select committee, a bill known as the 'Dolly Varden Mines Railway Amendment Act, 1919', was passed unanimously by the Legislative Assembly on March 28, 1919. This legislation provided, first, that the time for completing the Dolly Varden railway should be extended until December 31, 1920; that the cost of construction of the railway, as ascertained by a judge of the Supreme Court of British Columbia, should be a charge on the assets of the Dolly Varden Mines Co.; that the company should have a reasonable time in which to pay off the claim of the Engineering

company, represented by the cost of the construction of the railway, and that if they did not choose to pay off this claim within the time provided in the Bill, the Taylor Engineering Co. should be under the obligation, within 14 days, of providing sufficient money to pay the unpaid wages incurred on the railway construction, and should satisfy the Minister of Railways of their ability to finance and operate the mines and railway, and upon complying with these requirements, the properties of the Dolly Varden Mines Co. should forthwith vest in the Taylor Engineering Co. as an estate in fee simple, subject to certain floating statutory charges.

These charges are set forth in detail in the Bill itself and consisted first of two that were owing by the Dolly Varden Mines Co., one a balance on the purchase price, and the other a mortgage; then a charge in favor of the Taylor Engineering Co. representing the cost of the railway construction, and lastly a charge in favor of the Dolly Varden Mines Co. representing the full amount of their investment in the mines and railway. The Bill provides that these charges shall be payable in the fixed order of priority out of the net proceeds from the operation of the mines, and it also provides that the amount of the third and fourth charges, namely the one in favor of the Taylor Engineering Co. and that in favor of the Dolly Varden Mines Co. shall be ascertained by a judge of the Supreme Court of British Columbia. These

NEAR THE MINE

counts were fixed by agreement at \$462,000 and \$613,000 respectively.

Immediately after the Act had been passed unanimously by the Legislature, a Judge of the Supreme Court was appointed, as provided for under Clause 3, and the charge in favor of the Taylor company was fixed at \$462,028 and the charge in favor of the Dolly Varden company at \$613,000. The Dolly Varden company failed to take advantage of Clause 4 of the Act and the premises therefore vested in and became the property of the Taylor company, as specified under Clause 5, the Taylor company having complied with all the requirements of Clause 6, and within the 14 days provided for under Clause 6 had incorporated the Taylor Mining Co., with an authorized capital of \$1,500,000, and had raised \$340,000 cash with which to pay the unpaid wages for labor due on the 1918 construction, and to provide for the extension of the railway and the equipment of the mine.

THE DOLLY VARDEN PROPERTY consists of eight claims, covering 212 acres and extending from the river to the summit of the ridge between the Kitsault river and Eyindsen creek. The camp and principal mine workings are about 1700 ft. above sea-level.

The orebodies occur as replacement deposits along fracture-zones in andesite. The wall-rock has been replaced by quartz, accompanied by considerable pyrite and smaller amounts of galena, sphalerite, native silver, ruby silver, argentite, and rhodochrosite. The maximum width of the lode is 30 ft., but it has not been followed continuously along the strike for more than 60 ft., as it has been faulted both before and after the deposition of the ore, the displacement apparently taking place in a north-westerly direction.

The lode has a general east and west strike and dips north at from 45° to 70° . It was first exposed by a series of cross-cuts and later by four tunnels and diamond-drilling. The development in June 1919, when the Taylor Engineering Co. came into possession, consisted of 2086 ft. of drifts and cross-cuts, 280 ft. of open-cuts, and 8990 ft. of drill-holes. A large amount of work has been done since then.

The ore-reserves estimated in June 1919 consisted of 40,500 tons of ore averaging 36.4 oz. silver. The average analysis of the ore shows:

	%
Insoluble	76.7
Silica	71.9
Iron	8.5
Lead	1.20
Zinc	0.02
Gold	0.0021
Alumina	4.1

The Wolf claims are about two miles farther up and on the opposite side of the Kitsault river. They comprise four claims covering 179 acres. The outcrops range in elevation from 420 ft. to 1780 ft. above sea-level.

The geology of the Wolf ground is similar to that of the Dolly Varden except that the veins appear to be more regular, as no displacement of any consequence occurs. The development in June 1919 consisted of 85 ft. of drifts

and cross-cuts, 772 ft. of open-cuts, and 4919 ft. of diamond-drilling.

Three veins have been exposed: they have a strike a few degrees east of north and dip 50° to 75° north-west. The width varies from 10 to 30 ft. In general the walls are well defined, and the estimated probable and possible ore in the Wolf has been placed at 120,000 tons of 15.4

MAP OF CLAIMS IN THE PORTLAND CANAL DISTRICT. THE DOLLY VARDEN PROPERTY IS MARKED BY SHADING

oz. silver and 430,000 tons of 3.1 oz., or an average of 550,000 tons of 5.7-oz. ore.

The company owns water-power rights on Trout creek, immediately adjoining the Wolf claims, from which it is estimated that an ultimate development of 2500 hp. is possible.

The Taylor Engineering Co. came into possession of the railway and mining properties on June 10, 1919, and during the season just closed they completed the railway to the mine, built a 2000-ft. aerial tramway from No. 4

tunnel to the railway grade, installed a steam-driven compressor of 550 cu. ft., equipped the mine, and commenced shipping on September 1. Between that date and the close of the railway on December 15 there was delivered to the smelters or in transit ore containing a total of 458,994 oz. of silver. The run-of-mine ore averaged 56.4 oz. per ton. During the season a deposit of native silver was uncovered that up to date has yielded something over 100,000 oz., the smelter returns from this ore ranging from 1200 to 2500 ounces.

At the present time the railway is closed down by snow, and a force of 50 men is at work at the mine, driving a low-level tunnel 230 ft. below the workings. A small amount of high-grade ore is being sacked and shipped by dog-sleighs, and a certain amount of the run-of-mine ore is being delivered over the tramway to the railway terminal to form a reserve for shipment in the spring.

War Minerals Relief Claims

The Committee on Mines and Mining, to whom was referred the bill (H. R. 13,091) providing for a review by the Court of Claims of awards to dissatisfied claimants under the war-minerals relief act, reports the same back to the House with the unanimous recommendation that the bill be passed.

The attention of the committee was first directed to this matter several months ago by the complaints of several claimants, and this bill was framed by the committee and unanimously agreed to after months of painstaking hearings, a part of which is printed.

The hearings of the committee were undertaken, not for the purpose of reviewing the findings of the War Minerals Commission, to whom the Secretary of the Interior delegated his authority under the law, but for the sole purpose of determining what additional legislation, if any, is necessary to carry out the purpose of Congress in enacting the war-minerals relief provision, which is section 5 of the informal war contracts relief act.

The committee is of the opinion that the commission erred in its interpretation of the legislative intent, its interpretation and application of the provisions of the act, and the application of the provisions of the law to the facts. The law under which claimants seek relief is said section 5 referred to and clearly and explicitly directed the Secretary of the Interior to—

*adjust, liquidate, and pay such net losses * * * and shall make adjustments and payments in each case, as he shall determine to be just and equitable * * * it shall appear to the satisfaction of the said Secretary that the expenditures so made, or the obligations so incurred by the claimant were made in good faith for and upon property which contained either manganese, chrome, pyrites, or tungsten in sufficient quantities as to be of commercial importance * * * that moneys were invested and obligations were incurred * * * in a legitimate attempt to produce * * * for the needs of the Nation for the prosecution of the war, and that no profits of any kind shall be included in the allowance of any of such claims, and*

that no investment for merely speculative purposes shall be recognized in any manner.

The language of the act as above quoted is clear, and if interpreted as the courts of the country have repeatedly held such statutes should be interpreted, the committee is of the opinion that the purpose of Congress can be fully carried out and a "just and equitable" settlement can be had of every legitimate claim. For the correct rule of interpretation and application of such a statute see *United States v. Dixon* (15 Peters), *United States v. Union Pacific Railroad Co.* (91 U. S.), *United States v. State of New York* (160 U. S.), *Smith v. Townsend* (110 U. S.), *District of Columbia v. Washington Market Co.* (108 U. S.), *McClure v. United States* (115 U. S.), *Monongahela Navigation Co. v. United States* (148 U. S.), *Stewart v. Kahn* (78 U. S.). For the reasons above stated the committee has not thought it necessary to amend the original act, but that the pending bill should be confined to giving to the dissatisfied claimants the same right that the original act gave to dissatisfied War Department informal contract claimants; that is, a review by the Court of Claims. By giving such a right to these claimants Congress will simply put them on an equal footing with the War Department claimants, as provided by section 2 of the original act of March 2, 1919.

While the committee has given consideration to the matters set out above, another consideration that moved the committee was the necessity from the standpoint of the Government and of Congress to have all of these claims finally adjudicated at a time when the facts were easily available. If this is not done, judging by the experience of the past, Congress would be called upon to consider private claims bills covering the claims of the different dissatisfied claimants; and not only from the standpoint of Congress is this to be avoided, but from the standpoint of the Government it is thought best to have these contentions finally reviewed now and finally settled.

THE PRODUCTION of asbestos in Quebec during 1919 totaled 135,861 tons, valued at \$10,932,189. This is apart from the value of the asbestos, a by-product of the asbestos mills, which gave 23,827 tons valued at \$63,011. As compared with 1918 it is an increase in value of \$1,912,290 or 21.2% and a decrease of 6514 tons or 4.6% in quantity. The quantity of rock mined and hoisted was 3,061,690 tons. Taking into consideration stocks on hand, 154,378 tons of asbestos was extracted from this ore, which corresponds to an average of 100.8 lb. valued at \$3.88 per ton of rock mined. In 1918 the average was 117.3 lb. valued at \$4.08, and 108.7 lb. valued at \$3.08 in 1917.

COPPER mining in Sweden has not been nearly so important of late years as in times past. The average yearly production for the period 1891-1895 was 23,941 tons, whereas in 1916 the output was but 1380 tons. In 1917, however, there was an increase to 13,193 tons. The principal mines are at Falun and Helsingborg. The latter, it appears, works the burnt pyrite obtained in the manufacture of sulphuric acid into copper.

Technical Writing: Jargon

By T. A. RICKARD

"The dictionary defines 'jargon' as 'barbarous or debased language'. This description does not suffice. Quiller-Couch has said, it is 'a kind of writing which, from a superficial likeness, commonly passes for prose in these days, and by lazy folk is commonly written for prose, yet actually is not prose at all'. The two main vices of jargon, he says, are 'that it uses circumlocution rather than short straight speech', like the Babu who reported his mother's death by saying: 'Regret to inform you, the hand that rocked the cradle has kicked the bucket.' Its other chief vice is that 'it habitually chooses woolly abstract nouns rather than concrete ones', like the newspaper statement, 'He was conveyed to his place of residence in an intoxicated condition', instead of saying, 'He was carried home drunk'. Jargon is 'an infirmity of speech', it is not journalese, but akin to it. 'Like respectability in Chicago, jargon stalks unchecked in our midst' and renders much technical writing ridiculous. It deals in periphrasis instead of going straight to the point, it loves the abstract rather than the concrete, it dabbles in words of sound rather than meaning. Avoid it, despise it, if you purpose earnestly to write well. 'In literature as in life he makes himself felt who not only calls a spade a spade but has the pluck to double spades and re-double.'"

Jargon is rampant in technical publications. Catalogues and other advertisements are conspicuous offenders, but with these the critic is not concerned, except in so far as such 'write-ups' pretend to follow the style set by technical journals and by the transactions of technical societies. Here is an example, taken from a reputable paper:

(1) "The next proposition was to take out the rock to a depth of 20 ft. and build up an underground wall to carry the weight of the caisson and make the permanent seal to keep out all water. To avoid the possibility of jarring loose any of the temporary sealing blocks or breaking back under them the rock which was of a slaty nature, this excavation was started by channelling out for a depth of 5 ft. all around the shaft about 1 ft. inside of the blocking. The rock was then taken out in the ordinary manner with two shaft-bars and four rock-drills in operation. To further prevent the jarring of this blocking the rock was taken out in 5-ft. benches only. This made the work necessarily slower, but it was deemed advisable and so proved, for, notwithstanding the care exercised, certain leakages occurred which made the rock

excavation slow on account of the shifting of pumps, taking off and putting back suction pipes, etc. This rock, as above mentioned, was a species of sand slate which would break back a considerable distance from the line of holes."

I shall not attempt to revise it, for it needs to be re-written by one possessing the detailed information that the writer has attempted, unsuccessfully, to impart. To many it may not seem utterly bad, but it is obvious that only absolute need of the information would induce anybody to read it.

The foregoing example shows how the English language is mishandled in America; now I shall give you an example to show how our language is maltreated in the country of its origin. The following quotation is taken from a book on petroleum recently published in London.

(2) "In this vaporizer, which works efficiently with any of the refined flash-proof lamp oils, the mixture is only heated to the comparatively low temperature of 300° to 400°F., in which connection it is well to understand that the more perfectly an oil is atomized the lower is the temperature necessary to its combustion, which is an advantage, if not off-set by the necessity for a more than corresponding complexity of apparatus, which in this case, as will be seen, requires an air pump and for the fuel to be contained in a tank subject to a pressure of 8 to 15 lbs. per square inch; and this again obviously necessitates a separate hand pump, or a pressure supply for starting."

The errors are so many that the entire paragraph needs to be re-written. Why does he hyphenate 'flash-proof' and not 'lamp oils' and 'air pump' or 'hand pump'? He uses 'which' with irritating frequency; he employs the abstraction 'complexity of apparatus' instead of the concrete 'complex apparatus', besides a plain error of grammar, namely, "requires . . . for the fuel to be contained". The writer is an educated engineer, but he disregards the obligations of an educated man.

Here follows an attempt to describe the operation of a machine-drill in a mine:

(3) "Following the shooting, the *mucker* begins his work, the drill man climbs to the top of the *muck*, and by the time the four feet of ground shot down is *mucked out*, he is again ready to shoot his round of holes."

"Muck", "muck", "muck"—it is the very muck of writing. The word means filth or manure. It is used as a synonym for 'dirt', the miner's term for broken rock. Thus 'muck' refers to the shattered rock resulting from blasting, which is not in the least filthy. Shovelers, that is, those who shovel the broken rock into the car at the face of a level or cross-cut, are now called 'muckers'. What gain is there? 'Shoveler' is significant, 'mucker'

*A chapter from the book on 'Technical Writing', just published.

†These quotations are from a lecture delivered at Cambridge by Sir Arthur Quiller-Couch. 'The Art of Writing', 1916.

is the rubbish of words.

The next example comes from a description of the small locomotives used in mines. It reads:

(4) "Face gathering, wherein the locomotive must enter the room, imposes conditions which call for distinctly special treatment in the design and equipment of a locomotive of high efficiency. The ordinary haulage locomotive in nearly all cases is totally unfitted to this work, which involves operation in narrow quarters, around sharp curves, over poorly laid tracks, etc. The locomotive of real value in room work is one which, by reason of proportions and construction, will go wherever a mine car will run, and with equal facility. It must be compact, no wider than the wheels, with short wheel-base and small wheels, and without long overhang at either end."

This is the sort of thing that makes a technical description seem like a cryptogram or a slab of picture-writing from Nineveh. To anyone versed in the subject of locomotives for underground use, this paragraph is intelligible, but only that. It succeeds in making the subject as uninteresting as possible and places the meaning as much beneath the surface as the locomotive itself.

The last two examples come from 'write-ups', the trade name for a eulogistic description of a manufactured article, prepared in the interest of the manufacturer and written by a man more accustomed to the use of a screw-driver than a pen. The worst writing concerning technical matters is to be found in such disguised advertisements. They ought to be attractively written, to serve their purpose; in failing to do so, they illustrate the essential ineffectiveness of bad writing.

Grammatical correctness is no excuse for a statement that is likely to cause trouble to your reader. He must have your consideration always if you expect to be recognized as an effective writer. A technical journal states:

(5) "The specifying by a mining company that no man may be employed by it unless he be a member of such an organization, though undoubtedly legal, is as contrary to social justice as the specifying that no member of any organization will be employed, or the refusing to recognize any employee as representing anyone or anything except himself as an individual."

That reminds one of a passage in 'Alice in Wonderland': "Never imagine yourself not to be otherwise than what it might appear to others that what you were or might have been was not otherwise than what you had been would have appeared to them to be otherwise."

Here is more technical writing of a supposedly serious sort:

(6) "The expenditure involved is only justifiable with the assured certainty of very large ore reserves having values materially above operation costs." I suggest:

"The expenditure involved would be justifiable only by the certainty of an adequate reserve of profitable ore."

A respectable engineer writes:

(7) "They would go to the lay-out and see if it was checked out; if found out to be laid out, the lay-out foreman would spend his time in looking for it, and if he

could not find it he would get out a new one."

Such stuff is a disgrace to the profession; moreover, it is proof of such want of intellectual power as to argue against the possession of technical understanding.

Shun outworn figures of speech, like 'a bolt from the blue', 'the swing of the pendulum', 'the cry is still they come', 'after us the deluge', 'the Mecca of their pilgrimage', 'the Phoenix from his ashes', 'open Sesame', and 'the labors of Hercules'. They rarely give point to technical description; usually they are mere tags, in the reporter's style—a style to be scrupulously avoided in technical writing. Abstain from the use of such verbal inanities as 'festive', 'pristine', 'erstwhile', 'materialize', and 'eventuate'. These are precious to the reporter, but taboo to the intelligent writer.

Take note of the fact that nonsense remains nonsense however much you may disguise it in a veil of words. We think in words, and when we lack clear words we lack clear thoughts. Clear thinking is necessary to effective speech or writing. The forceful utterances and keen analyses to be remarked occasionally in men devoid of academic training show that the question of clear statement depends upon logic. Correct speech—grammatical speech—is logical speech. The following is a quotation from an address delivered by a prominent financier in San Francisco:

(8) "Let us learn, then, to realize that each has his dominion and his empire of domination, in which by the exercise of these qualities that are alike in spelling success each may rise to a position of leadership, with potentialities of power as great in its sphere of action as that one of the many, to whom we look for the time being, because of some particular preference as a leader."

This is balderdash. It is "the delirious trimmings" of language.

Early Victorian elegance has no place in technical writing; for example:

(9) "The ore was relieved of its moisture through the medium of drying kilns." Meaning that:

"The ore was dried in kilns."

Nor do we want late Nevada uncouthness:

(10) "With the installation of the new air-compressor underground development is being prosecuted more rapidly."

Is the air-compressor underground or is it being used for development underground? Should a comma come before or after the word 'underground'? The rapid progress is not being made "with the installation" of anything, but by the new compressor, operating more machine-drills. You do not *prosecute* a development; for that involves the pursuit of an abstraction.

(11) "The tributer is assisted in the prosecution of his work by being given supplies."

'Prosecution', in this context also, is a foolish word, apart from being an abstract noun. Slovenly writers who use such words also use too many others. He meant to say:

"The tributer is assisted in his work by being given supplies"; meaning candles, dynamite, caps, and fuse.

12 "Gold Mountain was turned down by a *succession* of eminent engineers." It would be more to the point to give the names of some of the engineers.

13 "He extracted the gold in the residue, thus *doing away with* [obviating] the *necessity* for [need of] re-handling it."

It was not the 'necessity', but the 're-handling', that he wished to avoid. Was it the gold or the residue that he was trying not to 're-handle'? He meant to say: "He extracted the gold in the residue, thus avoiding re-treatment."

Slovenliness in writing is due not to poverty of ideas but to careless thinking. It may escape censure because the majority of readers are uncritical and too patient. Given a careless writer and an equally careless reader, you have a performance about as profitable as a lecture to the deaf.

(14) "The Lake Superior copper mines are making a good recovery from the disorganized condition in which the long persistence of the strike put them."

Here you have the abstract phrases "the long persistence" and "making a good recovery" instead of a concrete statement saying that the strike had lasted long and that work at the mines had been resumed. 'Mines' is not the real subject of this statement, but the work being done in them. He—and he was an editor—meant to say:

"The working force at the Lake Superior copper mines is being re-organized and operations are being resumed after the long strike."

Statements that seem intelligible and are accepted by the patient reader without protest may yet fail to convey information accurately; and the docile reader—for every man that submits willingly to the attraction of an article, and reads it, is in a docile mood—either loses interest presently because of the vagueness of the discourse or struggles against the obstacles of clouded style until he is inclined to attribute the difficulty to a temporary mental inability of his own. The headaches of young students in their struggle to conquer knowledge from text-books are due more to the defective literary technique of the writers of the text-books than to difficulty inherent in the subject or to stupidity on the part of the learners.

(15) "The vein is a quartz fissure with a width of 1 to 6 ft., a dip of 50° to the north, and a filling of galena, sphalerite, pyrite, and chalcopyrite."

How can it be a fissure filled with quartz—for that is a quartz fissure, not a fissure in quartz—if it is filled with the four other minerals specified. Nor is the fissure attached to a width or a dip. He meant:

"The vein is from 1 to 6 ft. wide, it dips 50° north, and consists of quartz containing galena, sphalerite, pyrite, and chalcopyrite."

'Encounter' is a word greatly overworked. It means to meet hostilely or in conflict. The use of it in varying senses tends to vagueness.

(16) "The rocks indicate to the miner when *encountered* the general lower limits of the volcanics."

He means that where (not 'when') a particular rock is

found underground, there the lower limit (not 'limits') of the volcanic series is indicated. Therefore he might have said:

"These rocks, wherever found in the mine, indicate that the lower limit of the volcanic series has been reached."

(17) "The ore-bearing volcanics are *seemingly of more importance to the district from a gold-producing standpoint* than was at first supposed."

He meant that the volcanic rocks had a greater influence upon the deposition of gold in the district than had been supposed. He used 'seemingly' three times in eight lines of his manuscript, and you can infer from that how careless he was.

(18) "Some difficulties are *encountered* by the formation of sodium sulphate in the roasting furnace, *which dissolves together* with the sodium chromate."

Here 'encountered' means 'caused'. The wrong use of 'which' makes the writer state that the furnace 'dissolved'. The omission of the hyphen suggests that the furnace was 'roasting'. 'Together' is redundant. What he meant to say was:

"During the process of roasting, sundry difficulties are introduced by the formation of sodium sulphate, because it dissolves with the sodium chromate."

All these pluralities, generalities, and abstractions are the mark of jargon. As Quiller-Couch says: "To write jargon is to be perpetually shuffling around in the fog and cotton-wool of abstract terms: to be forever hearkening, like Ibsen's Peer Gynt, to the voice of the Borg exhorting you to circumvent the difficulty, to beat the air because it is easier than to flesh your sword in the thing."

Avoid extravagance. One of the chief obstacles to precision in writing is prolixity, the employment of superfluous words. Shy at such phrases as 'with regard to', 'in respect of', 'at the same time', 'as a consequence of', 'in connection with', 'from the standpoint of', 'on the basis of', 'of such a character', 'to any extent', 'according as to whether', 'on the whole', 'more or less', and so forth. Occasionally one or another of these unlovely locutions may be useful or necessary, but resort to them grudgingly, treating them as first cousins to jargon, which is the newspaper prostitution of our language.

(19) "With regard to the process, the principal difficulty that arose in *connection with* the operation of it was *the large amount of dust*; the success of it therefore depended *as to whether* it could, *or could not* be collected without incurring a *more or less* prohibitive expense."

The 21 words italicized are mere 'empties' in the train of thought. Note too the careless use of 'it'; the first and second refer to 'process', but the third refers to 'dust'. He might have said:

"The success of the process depended upon the economical collection of the dust made during the operation."

(20) "For it is *well known* that man's methods are ever changing while Nature's laws upon which they depend are invariable."

Two unnecessary and insipid clauses are interjected

under the false impression that they give dignity to the statement. How much stronger it sounds thus:

"For while man's methods are ever changing, Nature's laws are immutable."

(21) "Mistakes in assaying are far commoner than is generally thought to be the case."

"Mistakes in assaying are more common than is generally supposed."

(22) "Perhaps a few notes as to some of my experience in connection with mining in Colombia will be of interest."

"Perhaps a few notes on my mining experience in Colombia will be interesting."

(23) "The special difficulty in the case of flotation arose in connection with the treatment of the concentrate."

This might be changed to

"The special difficulty in using flotation presented itself when treating the concentrate."

Or, preferably,

"The main obstacle to the use of flotation was difficulty in treating the concentrate."

(24) "Any lumps of more or less [nearly] pure chalcocite were but superficially altered."

A mining journal says:

(25) "A particularly striking thing of the last Anaconda report is the exhibit of that company as the great metallurgical concern that it is."

The superfluous words are indicated. The statement can be amended thus:

"The latest Anaconda report exhibits that company as a great metallurgical concern", or

"This report exhibits the Anaconda as a great metallurgical enterprise."

Another author wrote thus:

(26) "So far as the writer is aware, the process has not been applied to any ore in this country, but there can be no doubt that there are many instances where it could be successfully applied."

This is a windy performance. What he wanted to say was:

"So far as I know, the process has not been tried in this country, but there must be many ores to which it could be applied successfully."

(27) "Probably flotation is due to a combination of phenomena which [that] are rather high in the scale of complexity."

"Probably flotation is due to a combination of complex phenomena."

(28) "From the standpoint of [according to] this theory."

(29) "This is too important a matter to be treated from a careless point of view [carelessly]."

(30) "From a genetic point of view the genesis of the coralline limestone have [has] been most carefully studied." Delete the words italicized.

The last three examples are borrowed from 'Suggestions to Authors' by George M. Wood, the editor of the U. S. Geological Survey.

Such words as 'case', 'instance', 'nature', 'degree', 'character', and 'condition' should be used sparingly and with discrimination.

(31) "So in the case of these veins we have present a reversal of the usual case where native copper turns to sulphide in depth."

This statement is typical of a kind of jargon that masquerades as ornate speech. He meant to say:

"Thus these veins reverse the experience usual in mining, namely, the change from native copper to sulphide mineral in depth."

(32) "In the case of copper it is not advisable to leach the ore."

"It is inadvisable to leach the copper ore."

(33) "The surface is of a very uneven character."

Delete the words italicized.

(34) "The soft nature [softness] of the rocks."

(35) "The lowlands in some cases [places] contain lakes, the most conspicuous instances being Crystal, Glen, and Portage lakes."

Here 'instances' is an elegant variant of 'cases'. It should be deleted.

(36) "This is the only instance in the district of a copper mine that is wholly in the granite."

"This is the only copper mine in the district that is wholly in the granite."

(37) "In every case an alteration product should be identified with extreme care." Delete the words italicized.

As Mr. Wood suggests, the victim of this habit of using 'cases' and 'instances', or some other similar abstract term, should ask himself what he means by the word. What is the concrete thing about which he is writing? He is likely to discover that he is indulging in mere verbiage.

(38) "The miners returned to work in most instances."

They went to work in overalls. He meant: "Most of the miners returned to work."

(39) "Even in Carboniferous areas, only in one or two instances do the veins carry ore."

Substitute 'places' for 'instances'. Perhaps he means "only one or two veins carry ore."

(40) "The accident was due to the dangerous nature of the work and the fissile character of the rock."

It was not; the accident was due to the weakening of the rock by fissuring and the sudden fall of a large piece upon the miner working below.

(41) "A singular degree of mineralization marks the district."

Meaning that "intense mineralization characterizes the district."

(42) "The auriferous mineralization is distributed throughout the ore and consists of metallic gold and gold associated with iron pyrites."

This is thoroughly bad, from beginning to end. 'Mineralization' is the condition of being mineralized; how can a condition be 'auriferous', that is, gold-bearing. Next, how can 'mineralization' be distributed through-

out the ore, it is an abstract idea; he means gold, thus:

"The gold in the ore occurs free and associated with iron pyrite."

The word 'situation' is beloved by jargonizers; it is a type of the abstract, of the general, and of the woolly.

(43) "To meet this *situation* [difficultly] as it developed, *sand-filling* [the filling of stopes with sand] was introduced in 1908." The same writer continues:

(44) "Previous to this date some of the older mines had been showing signs of movement, and it became evident that preparation was necessary to *meet this tendency*, which was bound to increase in intensity as mining progressed."

'Tendency' goes well with 'situation'; both are abstract terms, the mere fog of an idea. He meant to say:

"Previous to that year some of the older workings had shown signs of movement, so that it became evident that a systematic effort must be made to check the settling of the ground, a condition sure to become worse as mining progressed."

(45) "He first went to Goldfield to examine a *mining situation* [mine] and then *located* [remained or resided] there for good."

To examine a situation is like fighting a chimera.

"He first went to Goldfield to report on a mine, and decided to live there."

(46) "This serious *situation with respect to dye-stuffs* has been splendidly met by the chemists of the country."

"This serious need of dye-stuffs has been met splendidly by the chemists of the country," or

"This serious deficiency in dye-stuffs has been overcome with splendid success by the chemists of the country."

(47) "The *situation in regard to fuel* is so alarming as to call for the most careful consideration."

He means: "The shortage of fuel at this time is so alarming as to demand serious thought."

The same writer continues:

(48) "Our *greatest* [best] opportunity for *success in meeting the fuel situation* [escape from the dilemma] lies in efficient combustion."

A mining lawyer writes:

(49) "An apex could not exist in *situations* [under conditions] *not greatly dissimilar* [similar] to those in the Jim Butler case."

(50) "The labor *situation* is passing through a period of unrest."

'Situation' is a mere abstraction; it is 'labor' that is unrestful.

(51) "He took an option on an *interesting situation* [promising prospect] on Canyon creek."

(52) "He liked the *situation* [the mine or property] and decided to invest his money in it."

(53) "The *easing up of the oil situation* was in sight. "The passing of the crisis in the oil industry was assured."

As might be expected, the jargonizer loves such an abstract term as 'values'.

(54) "In my tests made with a view of [to] studying

the form in which *lay the values* [the gold and silver exist] in such tailings I have been unable to detect any *values* [precious metals] in the tailing from our ore."

How would he make tests to determine "the form" of the gold and silver until he had ascertained the fact that they existed in the tailing? When a writer makes such statements, he is not to be trusted.

'Problem' is another word dear to the jargonizer in search of abstractions with which to obscure his want of accurate knowledge.

(55) "One of our serious *problems* is clean water."

He means: "One of our chief hindrances [or handicaps] is the lack of clean water."

(56) "*The problem presented by this difficulty* engages the attention of metallurgists." Delete the words italicized.

(57) "The water *problem* is a drawback to concentration."

"The large amount of water required is an obstacle to concentration."

'Standpoint' is a jargonistic decoration.

(58) "The portion of the range that is of interest from an *economic standpoint* extends due east and west about six miles."

"The portion of the range that is of economic interest extends due east and west for six miles."

'Eliminate' is another first cousin to jargon.

(59) "The presence of barite or gangue will in most cases *eliminate the possibility of using gravity concentration*."

He was writing about oil-shale.

"The presence of barite or other heavy minerals will usually prevent the use of gravity concentration."

(60) "One company has succeeded in treating this shale in a small retort, and is *contemplating the installation of* [planning to erect] a larger plant."

To 'contemplate the installation' is pure jargon.

(61) "The method has been employed *in connection with the Herreshoff furnace installation*."

"The method has been applied to Herreshoff furnaces."

(62) "The *problem of water-losses* was taken up coincidentally with the stack-loss determinations." He is referring to the metallurgy of quicksilver.

"The loss in water was investigated at the *same time* as the loss in fume."

It is likely that many of the examples quoted by me will seem to you by no means bad; in fact, they represent the kind of writing that is so common as hardly to call for comment by those whose critical faculties have not been awakened; yet, I assure you, the avoidance of just such jargon is essential to good writing. Jargon defeats its purpose; the thought fails to reach its destination; the cross-currents distract the tired reader's attention, they interrupt the voyage of his thought, which drifts with the flux of words and becomes stranded at length on a shoal of verbiage. Brevity is the soul of wit; conciseness is the essence of clarity; every unnecessary word tends to obscure.

The Future of Chromite in the United States

By SAMUEL H. DOLBEAR

After many years of production on an insignificant scale, the mining of chromite in the United States became an important industry in 1916. During the following two years production grew to 82,350 tons, in 1918.

Its principal applications to American industry are in the manufacture of ferro-alloys, chromium chemicals, and fire-brick. The industries manufacturing products from the raw ore and those consuming the manufactured products are large, representing investments of many million dollars.

Heretofore the raw material for the manufacture of chromium products has come chiefly from foreign countries, imported here from long distances by water. The cost of ocean freights, rather than an increase in the amount needed, brought about a demand for the American ore, at prices that made the exploitation of American deposits profitable.

The sudden cessation in demand in 1918 is too well known to require discussion. It was due, as is generally known, to the failure of the embargo on importation, while the Armistice served only to lock the gate that had already been closed. That the mandate of the war industries and shipping boards was totally disregarded can be shown no plainer than by a statement of importations of chromite during 1916 and 1917, when no embargo existed, and 1918 when it was supposed to have been effective:

Year	Long tons
1916	115,945
1917	72,063
1918	100,142

The importations under embargo exceeded by 33 $\frac{1}{2}$ % those of 1917 without embargo. Available supplies in the United States in 1918 were, therefore, 182,492 long tons of ore in addition to whatever stocks remained on hand from the previous year's business.

The normal pre-war consumption of chrome ore in the United States was about 48,000 tons per year for about 7 years preceding 1915. The rate of consumption grew steadily and rapidly in this period, increasing from 27,876 tons in 1908 to 65,180 tons in 1913 and 74,686 tons in 1914. During the war period the increase in demand was offset in part at least by difficulties in importation, uncertain domestic production, and restrictions on consumption and sale of chromite, more particularly its manufactured products.

There will continue an average yearly increase in consumption due to normal growth of business in this country. Economies in the use of chromite were, however, developed during the War. This is particularly true in refractories. Much less chrome brick is used than heretofore. The steel-mills will continue to practise these

economies until the price drops to a point where the economy disappears.

Compared with the intense activity of 1918, the past year presents a sorry contrast. Stocks in the hands of miners on January 1, 1919, were estimated at 42,687 tons.* Only a few hundred tons were shipped from these stocks during the year. Instead of 600 active operations, there were four or five; these mined and shipped only 1400 tons during the first six months. Most of this material was shipped to ferro-chrome plants in Colorado and California. Imports during the first ten months of 1919 were 55,380 tons or about 67,000 tons for the year.

The American chromite industry has declined to near oblivion. Efforts are being made by some of the producers to secure a tariff sufficient to protect domestic operations against cheap foreign ore. The chief competitive countries are New Caledonia and Rhodesia, in which countries the deposits are larger and purer than those in the United States. The Caledonian ore is produced by French convict labor.

The bill introduced in the House by Representative Julius Kahn, calls for a tariff of 60 cents per unit of 1% chromic oxide, equivalent to \$30 per ton on 50% ore. Prices quoted in January for 50% ore f.o.b. New York were 70c. per unit, or \$35 per ton. The immediate effect of the tariff would therefore be to raise the price of 50% ore f.o.b. New York to about \$1.30 per unit or about \$65 per ton.

During the four years that chrome ore was intensively mined, the deposits closest to the railroads were first operated. As they were exhausted and the price increased, new deposits were opened, each time reaching farther from transportation lines, until, in 1918, mines were worked 50 or 60 miles from rail. The ore was carried by pack animals, wagons, and trucks; and in many cases hauling costs constituted the principal item in the expense of production. No notable mines, comparable with those of New Caledonia or Rhodesia, were found. By the middle of 1918, it was well known that if production was to be maintained, it would have to be accomplished by concentration. Several operators had already built mills, and efforts at large-scale production were devoted to mines that had developed sufficient reserves of low-grade material. This was the condition at the close of the War and is the condition today. In no other way could American mines provide the quantity and quality of product necessary.

Chromite is an essential element of warfare. No military campaign could be successful without it. We now

*U. S. Geological Survey.

know clearly what we must expect if foreign supplies should actually be shut out. Domestic mines would have to produce larger quantities—somewhere between 75,000 and 200,000 tons per year during the period of isolation. Warfare with any of the leading sea-powerful nations might easily exclude importations from New Caledonia, Rhodesia, and other distant sources. With greater difficulty supplies from such points as Cuba, Brazil, and Alaska could be cut off.

It is important, therefore, that we should examine closely into the available supplies in America to determine if these are sufficient to justify exploitation and use in peace-time industry. If our chromite resources are bountiful and sufficient to last for a long period ahead, then there is no problem of national security involved. On the other hand, if the proved resources are deficient, depletion becomes at once a military problem. Stocks of chromite normally in the hands of users would be sufficient to last for six months if war-time economies are properly put into effect. It is necessary then that domestic mines be kept in readiness to assume responsibility of large production on six months notice. Experience in the recent war has taught us that a ponderous and long-debating Congress would require this length of time to visualize the situation and act upon it. It is essential for the safety of the nation that the domestic operations should retain their status as producers, or at least as potential producers ready to resume production on short notice. Deposits easily available were largely exhausted during the past five years. There remain, as the chief sources of ore, the mines situated at a distance from rail, necessitating hauling over mountain roads. If these roads are neglected, they will readily become impassable and eventually become obliterated. Concentration plants already erected must be maintained. If the owners are unable to operate them for profit, they will either crumble or pass into the hands of the junk-man.

My attitude is that of a protectionist. I believe in the development of American industries, and I do not want to see American labor reduced to the level of the peasantry of Europe for the benefit of competition. Moderation is essential in the practice of any doctrine, and any rule carried far enough finds the need for exceptions. The doctrine of protection and its complexities is too long a subject for discussion here.

The immediate effect of the tariff would be, as before stated, to raise the price of ore to about \$1.30 per unit f.o.b. New York. The value of the ore at point of shipment in the West would depend largely on the point to which the material is destined. The value in California would be determined by deducting from the New York price the freight between the mine and New York. Ore of 50% grade would be worth about \$48 per ton on cars on main-line points in California and Oregon at the present time. As ocean-freights and the cost of foreign production decrease, the price of American ore would have to drop an equal amount. At Chicago the price of ore would be the New York price plus the freight from the point of entry to Chicago. The tariff would, of course,

reduce the amount of ore consumed in this country.

Foreign manufacturers of leather, colors, and products into which chromium enters as an incidental item, being free from the burden of tariff on chromium, would be favored by the differential in cost of production, and these foreign goods, unless excluded, would enjoy a complete advantage over similar American-made goods. While this might also be overcome by tariffs, the American manufacturer would have to meet this disadvantage in attempting to market his wares in foreign countries. All of this is, of course, true of every product for which protection is sought.

SUMMARY. If supplies in America are sufficient to enable operation without hazard to the national security, the problem is one of protection against foreign mines.

If supplies are deficient and operation of American mines would imperil the safety of this country in time of war, the problem is military.

We cannot risk our national security on a guess that our resources are ample, nor on the assumption that operation will develop large deposits hitherto unknown. The field has been pretty thoroughly prospected and the latter is unlikely.

The U. S. Geological Survey is in possession of much information regarding these resources, and as most of the larger producers are claimants under the War Minerals Relief Act their properties have been, or will be, visited by engineers of the Bureau of Mines. A careful review and correlation of these data should make it possible to determine accurately in which class of problem the chromite industry belongs.

If we are self-sufficient, chromite should be encouraged in every possible way. If conservation is necessary for military reasons, our military departments should undertake the preservation of American deposits as potential producers. It is entirely precedent that the mines and equipment be purchased by military appropriation, the equipment and workings kept in order, and maintained. Such an act would parallel the Naval Petroleum Reserve, and the reservation for governmental purchase of petroleum and helium under the Oil Lands Leasing Bill.

Our experience in the War justifies a similar military survey of all of the so-termed war minerals, and the record should be revised at frequent intervals to correspond to current developments.

DURING 1918 Hongkong exported tin to the United States to the value of \$16,299,203. At that time the United States had to have tin at practically any price. During 1919, when conditions became more nearly normal, the United States was able to choose its tin where it could buy cheapest, and the result was that Hongkong-Yunnan tin could not compete in price with tin from the Straits Settlements, where it is produced on a gold basis. The tin exported from Hongkong to the United States during 1919 was valued at only \$496,115, and most of that was shipped in the last two months of the year on consignment for whatever price it would bring, to get it out of the way of the new year's stock of tin.

Arizona's Oldest Copper Mine

By F. Le R. THURMOND

The oldest copper mine in the State of Arizona is the Planet, situated on the Bill Williams fork of the Colorado river, about 15 miles from Swansea. It has been leased to the Consolidated Smelting Co., and a force of men is at work preparatory to commencing actual mining. The history of the mine dates from 1865, when rich oxidized ore was mined and hauled 12 miles to the

the price of copper was high, lessees mined and shipped about half a million dollars worth of copper, hauling the ore with trucks to Midway, a station on the Arizona & Swansea railroad. It is said that no ore was shipped that assayed less than 6% copper.

The ore mined to date has been oxidized, largely carbonate and silicate, with the latter predominating. Hematite or specularite is the principal gangue mineral. The orebodies occur in veins or lenses, in the pre-Cambrian complex, made up for the most part of granite gneiss, with many patches and areas of complex meta-

THE COMET SMELTER IN 1884

DETAILS OF BLAST-FURNACE AT THE COMET SMELTER

Colorado river. Here it was loaded onto flat-boats and floated to the Gulf of California, thence in sailing vessels around 'The Horn' to Swansea, Wales. About a million dollars worth of copper was thus produced before trouble with the Indians, added to the depletion of the richer orebodies, caused operations to be suspended.

In 1884 a smelting furnace with a capacity of 30 tons per day was erected and operated for five months. This plant is shown in the accompanying illustrations. One thousand tons of slag that it produced was shipped by lessees in 1917, the smelter returns from which showed an average copper content of 5%. When examining the remains of this slag-dump I found pieces of slag containing numerous shots of copper varying from one to four millimetres in diameter. From 1915 to 1917, when

morphosed sediments, the whole being intruded with mesozoic lavas, which seem to have given rise to the iron oxide segregations with which the copper is associated. Hematite-limestone contacts form the loci of the workable orebodies.

SHIPMENTS OF COPPER from the United States to Japan during 1919 were unusually heavy. Ordinarily Japan is not a large consumer of American copper. Attention has frequently been called to the possibility of Japan entering extensively into the manufacturing of copper and brass material. Approximately 70,000,000 lb. of copper was exported to Japan last year against only about 450,000 lb. in the previous ten years. The effort to capture the Asiatic trade in copper goods formerly held by Germany may be one incentive for these heavy purchases.

The McFadden Bill

To provide for the protection of the monetary gold reserve by the maintenance of the normal gold production of the United States to satisfy the requirements of the arts and trades, by imposing an excise upon all gold used for other than monetary purposes, and the payment of a premium to the producers of newly mined gold, and providing penalties for the violation thereof.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That on and after May 1, 1920, in addition to any existing tax now assessed or levied thereon, there shall be levied, assessed, collected, and paid a tax of 50 cents per pennyweight of fine gold contained in all gold manufactured, used, or sold for other than coinage or monetary purposes, by or for a manufacturer or dealer, or his estate, on or after such date, and upon the gold contained in any manufactured articles sold by any dealer or manufacturer, or his estate.

SEC. 2. That the Internal Revenue Department shall prescribe and provide a proper and sufficient stamp that shall be attached to or imprinted upon any and every manufactured article, or the package containing the same, in which gold is used, that may be sold after the 1st day of May, 1920, and upon all gold used in any form other than for monetary purposes after the said May 1, 1920. The stamps to be so provided and authorized to be sold and imprinted upon or attached to such manufactured articles, or the packages containing the same, shall be in such form, and shall be imprinted upon or attached to, the articles or packages, at such time and in such manner as may be provided by the rules and regulations of the Internal Revenue Department carrying this Act into effect.

That on account of the impracticability of suitably stamping finished dental restorative appliances, the Internal Revenue Department shall further prescribe such rules and regulations for the collection of the tax provided herein upon all gold used for dental purposes as will equitably protect the interests of the public; that all gold used by the Government for dental, medical, and surgical purposes, and all gold employed in dental services rendered to war-risk insurance patients by the United States Public Health Service, shall be exempt from the excise provided herein; and that all gold used in corrective and restorative dental work for children of both sexes not over the age of fifteen, and all gold used in dental infirmaries conducted for the benefit of the poor and not for private profit, shall be exempt from the excise provided herein.

SEC. 3. That all moneys collected pursuant to the provisions set forth in section 1 of this Act shall be paid into the custody of the Treasurer of the United States, and shall be kept by him in a separate fund designated as "the gold premium fund", and shall be used and paid out in accordance with the provisions of this Act as here-

in set forth, and for no other purpose; except that if, at the end of any current year, a balance has accrued in the gold premium fund over and above the amount necessary to pay the premium obligations that have accrued thereunder, it shall be the duty of the Treasurer to place said balance in the general fund of the Treasury of the United States.

SEC. 4. That from the gold premium fund, and any other funds in the Treasury of the United States not used for specified purposes, there shall be paid by the Treasurer of the United States, after the 1st day of May, 1920, and for a period of five years thereafter, to the producer of new gold in the United States or its possessions a premium of \$10 per fine ounce, in accordance with the provisions of this Act hereinafter set forth.

SEC. 5. That for the period commencing May 1, 1925, both the tax and premium as herein set forth shall be readjusted annually by the Secretary of the Treasury, the Secretary of Commerce, and the Secretary of the Interior, meeting as an adjustment board for such purpose; that said readjustment shall be made in accordance with the commodity price index number of the fifth year of the five-year period hereinbefore designated as compared with the average commodity price index number for the first four years of said period; that the index numbers of all commodities governing this readjustment shall be those ascertained and published by the Bureau of Labor Statistics of the Department of Labor; that the said tax and premium as readjusted shall constitute the amount of tax and premium that shall be collected and paid during the year next ensuing; and that each readjustment shall be made annually prior to the 1st day of May of each succeeding year, which shall determine the amount of tax and premium to be collected and paid.

SEC. 6. That on and after May 1, 1920, every producer of gold from any mines in the United States or its possessions, who shall be entitled to the provisions of this Act shall deliver the gold so produced to the United States Mint, or its authorized agencies, accompanied by a sworn statement setting forth the place where the gold was mined, the dates between which it was mined and prepared for market, and that no gold obtained from any other source is contained therein. In the event any gold was recovered from ore by custom smelting or milling, the proprietor, or his managing agent, or an executive or managing officer of any such smelting or milling company shall make and deliver to the producer a sworn statement stating the date or dates on which such ore was delivered for smelting or milling and the date that the gold recovered from said ore was delivered to the producer and the amount of gold so delivered to him.

Upon the delivery of any such gold, accompanied by the sworn statement of the producer, or accompanied by the sworn statement of the smelting or milling agency, the Director of the Mint shall execute and deliver to such

producer a certificate setting forth the number of fine ounces of newly mined or smelted gold then and there delivered by such producer, and shall set forth the amount of premium to which the producer is entitled.

In the event that ore containing gold is delivered for smelting or milling by the producer of the ore to a custom smelter or mill, and in the usual smelting or milling practice the same cannot be treated without delay, the smelting or milling company may follow the usual smelting or milling practice, purchase said ore, and receive the certificate, under oath, of the producer, setting forth the time and place of the mining thereof, and pay to the producer thereof the monetary price of \$20.67 and the premium as herein provided upon each fine ounce of gold so recovered by said smelting or milling company, which, upon such payment, shall be entitled to all the rights of the producer of the ore as of the date of delivery of the ore to such smelting or milling company, and upon the presentation of the certificate of the producer, together with a certificate of such smelting or milling company setting forth all of the facts as required by the rules and regulations established hereunder, shall receive the same amount of money as a premium for such gold so produced and delivered to the smelter or mill as the producer may have received if such ore had been smelted or milled and the gold returned to the producer of the ore.

That every person or corporation so producing newly mined gold from any mines within the United States or its possessions on and after May 1, 1920, and who shall deliver the same to the United States Mint or its authorized agencies as herein provided shall be paid therefor the sum, amount, or consideration as now provided by existing law, and in addition thereto, shall be entitled to receive on the certificate issued by the Director of the Mint, as herein provided, the additional sum of \$10 for every ounce of fine gold so mined and delivered to the United States Mint or its authorized agencies: *Provided*, That no gold bullion in any form whatever shall be issued or delivered to such gold producer in payment of, or in exchange for, any such newly mined gold so delivered as herein provided: *Provided further*, That the Director of the Mint may coin any such gold so produced and delivered and deliver to any such producer the coin minted therefrom, or the Director may deliver to any such producer coin in exchange for such newly mined gold, as is now authorized under existing laws.

SEC. 7. That upon the delivery of the gold and the sworn statements as hereinbefore set forth to the United States Mint, or its authorized agencies, a certificate shall be issued by authority of the Director of the Mint to the producer or his order certifying that the holder thereof is entitled to receive from the Treasurer of the United States the sum specified therein as payment of the premium for the production of new gold from the funds in the custody of the Treasurer herein provided.

SEC. 8. That any person who purposely or knowingly shall violate the rules and regulations of the Internal Revenue Department referring to the collection of this excise imposed upon gold for other than coinage or

monetary purposes, or who shall sell or dispose of any article containing gold to which there has not been affixed, or upon which there has not been imprinted, the proper stamp, without first affixing or causing to be imprinted thereon such stamp as shall be provided by the Internal Revenue Department of the United States, shall be guilty of a crime against the United States and shall, upon conviction, be imprisoned not more than five years or fined not more than \$10,000, or both.

SEC. 9. That any person, whether acting for himself or as agent or officer of any gold producer, smelter, refiner or milling company, who purposely or knowingly, by any art, way, or means, shall himself adulterate, or procure or solicit another to adulterate, any gold presented to the United States Mint for which a certificate for the payment of a premium as provided herein is requested, or who shall purposely or knowingly make a false statement, or procure or solicit another to make a false statement, in any statement or certificate required herein, which would entitle the producer to receive a premium on the production of gold herein provided for, shall be guilty of a crime against the United States and shall, upon conviction, be imprisoned not more than five years, or fined not more than \$10,000, or both.

SEC. 10. That all administrative, special, or stamp provisions of law, including the law relating to the assessment of taxes, so far as applicable, are hereby extended to and made a part of this Act, and every person liable to any tax imposed by this Act, or for the collection thereof, shall keep such records and render, under oath, such statements and returns, and shall comply with such regulations as the United States Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, may from time to time prescribe.

Whenever in the judgment of the United States Commissioner of Internal Revenue necessary, he may require any person, by notice served upon him, to make a return or such statements as he deems sufficient to show whether or not such person is liable to tax. The Commissioner, for the purpose of ascertaining the correctness of any return or for the purpose of making a return where none has been made, is hereby authorized by any revenue agent or inspector designated by him for that purpose, to examine any books, papers, records or memoranda bearing upon the matters required to be included in the return, and may require the attendance of the person rendering the return or of any officer or employee of such person, or the attendance of any other person having knowledge in the premises, and may take his testimony with reference to the matter required by law to be included in such return, with power to administer oaths to such person or persons.

SEC. 11. That any person required under this Act to pay, or to collect, account for and pay over any tax, or required by law or regulations made under authority thereof to make a return or supply any information for the purposes of the computation, assessment or collection of any such tax, who fails to pay, collect or truly account for and pay over any such tax, make any such return or

supply any such information at the time or times required by law or regulations, shall, in addition to other penalties provided by law, be subject to a penalty of not more than \$1,000.

Any person who wilfully refuses to pay, collect, or truly account for and pay over any such tax, make such return or supply such information at the time or times required by law or regulations, or who wilfully attempts in any manner to evade such tax shall be guilty of a misdemeanor, and, in addition to other penalties provided by law, shall be fined not more than 10,000 or imprisoned for not more than one year, or both, together with the costs of prosecution.

Any person who wilfully refuses to pay, collect, or truly account for and pay over any such tax, shall, in addition to other penalties provided by law, be liable to a penalty of the amount of the tax evaded, or not paid, collected, or accounted for and paid over, to be assessed and collected in the same manner as taxes are assessed and collected: *Provided, however,* That no penalty shall be assessed under this subdivision for any offense for which a penalty may be assessed under authority of section 3176 of the Revised Statutes, as amended, or of sections 8 or 9 of this Act, or for any offense for which a penalty has been recovered under section 3256 of the Revised Statutes.

The term "person" as used in this section includes any officer or employee of a corporation or a member of or employee of a partnership, who, as such officer, employee, or member is under a duty to perform the act in respect of which the violation occurs.

Secondary Metals

Part of the metal or metals contained in drosses and skimmings undoubtedly is recovered and re-used several times in one year. Similar conditions prevail in the use of all junk or waste material. New clean scrap is sold and becomes mixed with old scraps contained in articles that have been used and discarded. New clean clippings of zinc, tin, and aluminum are usually carefully segregated from other scrap metals, but many dealers in metals, or smelters, do not keep separate records of other new clean scrap and old used metals. The quantity of the various metals contained in numerous alloys made partly or wholly from secondary material cannot be definitely ascertained. The figures given by the U. S. Geological Survey are only approximate, but they are the only available data of an important industry.

The value of the secondary metals, exclusive of gold, silver, platinum, iron, steel, and ferro-alloys, recovered in the United States decreased from \$295,854,900 in 1917 to \$264,298,900 in 1918. The decrease was due to much lower average prices of copper, zinc, lead, and antimony. The value of the secondary platinum, iridium, and palladium recovered in 1918 amounted to \$5,077,000, which was nearly as much as the value of the platinum and allied metals imported for consumption in the United States in 1918.

The value of the old jewelry, dental waste, silver spoons, tableware, ornaments, and other articles containing gold or silver remelted or refined in 1918 was more than \$25,500,000. Mints and refineries reported the recovery of 8,526,122 oz. of silver and \$16,931,600 of gold from waste or discarded material. Jewelry and dental waste are the largest sources of secondary gold, and silverware and photographic wastes of secondary silver. The increased value of silver naturally resulted in the return of large quantities of old spoons and other tableware to the melters, and the large increased sales of photographic material resulted in an increased quantity of silver used in that industry. Some idea of the recovery of silver from moving-picture laboratories is furnished by the fact that one small refining plant reported the recovery of more than 30,000 oz. of silver from photographic waste. It is difficult to estimate the value of ferrous scrap remelted in 1918. Estimates of the quantity vary from 12,000,000 to 14,000,000 long tons. Owing to the enormous consumption of iron and steel for war purposes there was a large increase in the quantity of scrap ferrous alloys available. A considerable part of the scrap ferrous metal contained nickel, tungsten, manganese, chromium, vanadium, molybdenum, or other alloys, which made it many times more valuable than the ordinary commercial iron and steel scrap, though the market is limited and some knowledge is necessary to find prospective purchasers. All of this high-priced ferrous metal scrap will be absorbed into trade channels, although it will take considerable time to use the large accumulations of nickel steel and other special ferrous alloys. There continued to be a considerable quantity of scrap metals from abandoned steam and trolley railways, but the quantity of old metals marketed by operating railway companies was less than usual. Buying of new material by railways was restricted to urgent needs, consequently smaller quantities of old rails, car wheels, and other equipment were discarded. The railways are on the whole the largest producers of most kinds of metal scrap, as well as the largest users of new and remelted metal. It is estimated that the railways discard more than 8,000,000 tons of iron and steel yearly. One large railway company estimated that its purchases and manufacture of bearing metals in 1917 amounted to more than 21,000,000 pounds.

The dealers and brokers in ferrous metals think that the prices paid by users of iron and steel scrap since November 1918, have not been fair in that they have showed a much greater percentage of decrease than the prices of iron and steel products made from this old material.

It is impracticable and unnecessary to segregate the statistics relating to the melting, refining, and using of secondary metals according to States, but more than 90% of the refining and smelting of drosses and scrap metals in the United States is confined to the territory east of St. Louis and north of Ohio river. Nearly all the secondary aluminum was reported from the States of Ohio, Michigan, Connecticut, Illinois, Indiana, and Wisconsin.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

SILVER MINES NEAR PRESCOTT ARE BEING REVIVED.

PRESCOTT.—A large consolidation of mining properties has been effected by the newly organized Peak Silver Mining Co. The officers are H. H. Keays, president; Charles A. Weidler, secretary and treasurer; and J. E. Pierson, general manager. The consolidation takes in the old Emporia, Black Horse, Benedict, Yellow Jacket, Lluvia de Ora, Happy Home, Bornite, and Lost Burro properties which are in various stages of development. Unwatering of the Black Horse shaft, 130 ft. deep, is in progress. The last work done thirty years ago resulted in shipping three carloads of high-grade silver ore. A gasoline hoist is being put in. The best developed property in the group is the Emporia, which has been a producer for a number of years until just prior to the War. Two shafts each 200 ft. deep and considerable lateral work constitute the development. It is estimated that 9500 tons of ore is available for immediate mining. The new company plans to use the oil-flotation process and a stamp-mill. The company also has available nearly 4,000,000 ft. of virgin pine timber, and a 2000-hp. water-power. Ore in former years has been mined profitably from six of the properties of the consolidation. The value of the visible assets of the company is estimated at slightly over half a million dollars. There are 15 known parallel veins of ore in a width of three miles, which carry gold, silver, and copper. It is expected that high-grade silver ore will be found in the Black Horse as soon as the old workings are cleaned out. The Emporia mill is to be equipped with flotation early this spring. The area that is being taken over includes 62 mining claims or about 1220 acres on the Hassayampa river 10 miles south of Prescott.

Mine-owners of the Prescott district have been watching with interest the operations at the Monte Cristo silver mine, on Groom creek, 8 miles south of here. W. H. Worthington and Grover Hubbel, of Wickenburg, have acquired this old mine by purchase. The shaft is 400 ft. deep, with much work done on levels above the 300-ft. point. The main orebody is from 2 to 3 ft. wide, with a rich streak of shipping ore 15 in. wide in the centre. Recently, the owners started a 10-ft. K & K flotation machine in the old mill, which is now making a 95% recovery. A smaller sized K & K machine is to be used as a cleaner and will increase the capacity to 40 tons per 24 hours and is expected to raise the recovery.

The success of this flotation plant in the silver district

south of Prescott, which begins 4 miles from town and extends 30 miles beyond Crown King, a distance of at least 65 miles south from Prescott, means the re-awakening of the mining spirit of the entire district. There was no process to successfully handle the sulphide silver ores prior to the development of the flotation process. Plans are already being made by five new companies, which have taken over old and partly developed properties of this district, to use the flotation process in old mills which have not turned a wheel for ten to forty years.

Announcement is made of the purchase of the Gladiator and War Eagle gold mines, at Crown King, by the Philadelphia Mining Co., which owns the adjoining property on the west. A tunnel on the older property, 1200 ft. long, is to be used in the development of the newly acquired properties, which will give a depth of 1200 ft. under the apex. Flotation will be used in the old mill. George Harrington, of Crown King, is the principal in the deal in Arizona.

MAYER.—The Half Moon Copper Co. has found rich copper glance ore in a drift 170 ft. north from the bottom of the 500-ft. shaft. The streak is 12 in. wide and assays 49% copper. The face of the drift is in milling ore. In the west cross-cut, three feet of chalcopryite ore averaging 4% copper, has been cut. The property is half a mile south of the Arizona Binghamton mine, in the Copper Mountain district, five miles north-east of Mayer.

MIAMI.—It is reported that the Old Dominion Copper Co., by sinking to the 1900 and 2000-ft. levels, has increased its ore-reserves by 500,000 tons. Copper oxide occurs in the 1900-ft. level owing to the displacement of the Pinal Creek fault; this is believed to be of great importance as it proves a westerly extension of the orebodies. The depth to which the ore can be profitably worked will depend on the amount of water to be handled, 7,000,000 gallons now being pumped. Under the present reduced operations the mine is producing 850 tons of ore per day.

The Iron Cap Copper Co. shipped 7300 tons of ore during March. Work on the new mill is reported as progressing rapidly. It should be completed by the middle of May. The treatment in the new mill comprises rod-mills for both primary and secondary grinding; roughing tables, following initial grinding; secondary grinding; flotation; drag classifiers; and tabling of the sands. The ore to be treated is mostly bornite and it is expected that an extraction of 95% will be obtained. The Iron

Cap ore is at present being treated in the Inspiration mill.

It is reported that development at the Arizona Commercial has opened ore between the 600 and 1600-ft. levels up to a width of 40 ft. running 5% copper. The plans for the new 1500-ton mill of the Old Dominion, which is to handle the milling ore of the Arizona Commercial, have been completed.

Preparations are under way to renew churn-drilling at the Porphyry Consolidated. C. E. Bosworth, mining geologist of Phoenix, is making a surface examination of the property. Any new ore developed pending negotiations for the sale of the Porphyry Consolidated property to the Inspiration Consolidated Copper Co. will be taken care of by increasing the purchase price, it is announced.

MONTANA

STRIKE OF THE MINERS AT BUTTE.

HELENA.—The Muskegon mine, operated by the Lump Gulch Mines Co., has a large body of ore blocked out on the 230-ft. level. Extensive cross-cutting throughout the mine it is expected soon will put the property on the list of producers.

POTOMAC.—The Potomac Copper Co. is now employing 30 men. No. 4 tunnel is 1300 ft. long and with 400 ft. additional driving it is expected to reach a point directly under the surface outcropping on the mountainside 500 ft. above the tunnel portal. This outcrop is 300 ft. long and 100 ft. wide and averages 3% copper and 10 oz. silver. The tunnel-face is now in quartzite containing seams of copper. The mine is situated eight miles from a railroad. It is reached by a road that was constructed last summer at a cost of \$10,000. W. I. Higgins is superintendent.

COOKE CITY.—The Glengarry Mining Co., owner of the Scotch Bonnet group of properties, expects to commence shipping ore as soon as weather conditions will permit. The ore from the mine is transported to Gardner by truck, 53 miles, and then by rail to the smelter. Tunnels show a block of high-grade ore 42 ft. deep, 36 ft. wide, and 74 ft. long. From 40 to 50 tons of ore is expected to be shipped daily. Other properties that will operate this year are the Republic, the Yellowstone Mining Co., and the Western Power & Smelting Co. The Republic has worked all winter and has more than 5000 tons of ore on the dump ready for shipment. This ore promises to assay close to \$100 per ton in gold, silver, and copper. W. D. Marlow is president.

BUTTE.—The Tuolumne company, operating the Main Range group, mined and shipped 45,000 tons of ore during March, which was a 40% increase over the February production. Smelter returns show assays of 3% copper and 12 oz. silver. The Spread Delight vein has been penetrated and bears out all expectations. Already timber to the width of four sets has been placed without reaching the hanging wall. The cross-cut in the direction of the Rory O'Moore vein has encountered a fault which has delayed reaching the expected orebody.

The Homestake Mining Co. has let a contract for 900

ft. of tunnel on its property on Big Trout creek in the Thompson Falls district. The vein varies in width up to 42 ft. The copper ore is found in a kidney-type formation.

The mines of Butte were closed down on April 20 by a strike called by the local I. W. W. Heavy picket duty by the 'wobblies' made the tie-up complete. Enough of the engineers, pumpmen, and metal-tradesmen succeeded in getting to work to prevent the mines from being flooded or otherwise damaged. No ore is being hoisted. It is estimated that close to 12,500 men are idle as a result of the strike. Armed deputies clashed with pickets on the Anaconda road and 16 of the latter were wounded, some seriously. Governor Stewart has been appealed to for protection and troops are expected to arrive. Many miners are leaving the camp and an acute shortage of labor is expected when operations are resumed. The strike was engineered and is almost entirely dominated by a foreign-born element. The demands are listed as follows: (1) Release of industrial and political prisoners; (2) six-hour day collar to collar; (3) minimum daily wage of \$7; (4) abolition of the rustling card; (5) abolition of the contract and bonus systems; and (6) two men on each machine and on all other work.

LIBBY DISTRICT.—The Lukens-Hazel property has added to its reserve by discovering a 9-ft. vein of gold-quartz ore. The mill is nearing completion. A satisfactory adjustment of the litigation tying up the Snowstorm mine has been made. The buildings are being repaired and early operation is looked for. Cady, Sheffield, and Crideman report satisfactory development progress on their Automobile group of claims.

NEIHART.—The Neihart Silver Mines Co. has hopes of developing a large orebody through the 100-ft. level of the Broadwater tunnel. This ore is 200 ft. from the Blackbird claim. Samples assay from 30 to 200 oz. silver per ton. It is planned to connect both the Blackbird and Silver Belt properties with the Broadwater tunnel for economical operation and more advantageous exploration. Transportation from the Broadwater is by aerial tram.

The Moulton mine of the Cascade Silver Mines Co. has made such rapid development as to necessitate the purchase of a new air-compressor. The finds reported in the lower levels are holding out as work progresses.

NEVADA

TONOPAH MINERS STRIKE AGAIN.

TONOPAH.—Labor trouble has broken out again, following persistent rumors of radical activities which have continued since the settlement of the strike last fall. The trouble has spread to the Divide district after practically closing the Tonopah mines. The radicals in control of the situation have presented a list of demands that is in some respects humorous. They ask the immediate release of all industrial and political prisoners, a 6-hour day from collar to collar, with a minimum wage of \$7; two men on all machines, clean sheets twice every week in the bunk-houses, "with springs and mattresses and plenty of blankets"; one man to a room, his bed to be "made

up each day and his room to be cleaned of all dust and other things which may accumulate". After reading the demands a mine operator said: "I knew it was coming to this. If we give them their demands now within three months we shall have a strike based on a demand for valets, one for each miner."

YENINGTOS.—The Rockland Mining Co., the principal interest in which is held at Canton, Ohio, has been declared bankrupt, with an indebtedness of \$55,000, and the trustee has been ordered to sell the mine and equipment on the claims 25 miles south of Mason valley. Dissension among the stockholders, resulting in their refusal to complete payments on \$125,000 worth of machinery, is given as the reason for the company being bankrupt. The vein, of an average width of 2½ ft., has been opened to a depth of 1300 ft. The principal content of the ore is gold, with silver associated with antimony and arsenic in sufficient quantity to make the ore refractory. The reduction plant is an all-sliming cyanide mill of 75 tons capacity. The mine is reported to have produced \$350,000 gross, but lack of development work in recent months leaves little in sight.

ELY.—A 100-ton cyanide mill has been completed and will soon start operating at the old Argus mine at Taylor, 16 miles south of here. The mine is opened to a depth of 300 ft. and it is said to have produced 2,000,000 oz. of silver ore in the early days. It is estimated that ore in surface dumps is ample to keep the mill supplied for more than a year. The mine dump is estimated to contain 265,000 oz. of silver, and 18,000 tons of tailing gives an average assay return of over 6 oz. silver and 80 cents in gold. The estimated silver content per ton of the mine dump is 14 oz. The mine and mill are owned by the Wyoming Mining & Milling Co., of which E. P. Bowman, of Cody, is manager. The claims are across Steptoe valley from the Ward lead-silver mine.

WONDER.—It is reported that George A. Manning, of New York, has financed a company to take over and operate the Vulture, Bald Eagle, Spider Wasp, Goldconda, and Dickey V. groups. The affairs of companies formed by Henry Weber to develop these groups over 10 years ago led to two noted cases in the criminal court in Goldfield, in which Weber, promoter of the Atlanta Mines Co. in Goldfield, was the defendant. The rise in the price of silver led to the formation of the new company, as the ores of the district contain four parts silver to one of gold.

BELMONT.—The Consolidated Spanish Belt company, 7 miles south-west of here, has started the erection of a 10-stamp mill to treat silver ore assaying from \$10 to \$30 opened since work was started by the company in December 1916. The Spanish Belt owns the old Barcelona and San Pedro mines, which produced rich ore many years ago. The San Pedro shaft was reopened by the present management and the Ernst tunnel workings, from which a production of \$500,000 is said to have been made in the early days before the miners were driven out by water, were drained by a 1300-ft. tunnel. Since then thousands of feet of work has been done and for several

months regular shipments of high-grade ore have been made.

DIVIDE.—A 9-ft. width of ore estimated to have an average value of more than \$100 per ton has been opened at a depth of 310 ft. in the Victory and shipments have been started. The 9-ft. width includes 1 ft. of the richest ore ever found in the district and 5 ft. of \$139 ore. The ore was found in a drift from a 110-ft. winze from the 200-ft. level and the winze will be sunk an additional 50 ft. and another cross-cut will be driven to the vein at this depth.

QUARTY MOUNTAIN.—The Bell group of claims on Quartz mountain, 12 miles east of Goldfield, has been

MAP OF TERRITORY SURROUNDING BUTTE

optioned by M. J. Conroy, of Los Angeles, for a price reported to have been \$80,000. The group consists of eight claims on the eastern edge of the Goldfield hills. The vein is 110 ft. wide and the following assays were secured from the surface by Corrin Barnes, a Goldfield engineer who made the report on which the option was taken. An 8-ft. width, \$8; 18 ft., \$17; 24 ft., \$5.20. The gold is entirely in flakes embedded in the quartz and in some cases embedded in the quartz phenocrysts of the original rock. The best assays were secured over a width of 60 ft. The vein, which has a general northerly strike and dips 70° E., has been traced on the surface for 1500 ft. It is estimated that a tunnel now 160 ft. long will cut the vein at a depth of 140 ft. if continued an additional 65 feet.

COPPER CANYON.—George B. Thatcher, former Attorney General of Nevada, and associates have been notified that the United States Supreme Court has denied a motion for a re-hearing in their case against Joseph Ralph, which involves ownership of the Copper canyon gold placer deposits in Humboldt county. Thatcher and his

partners now expect to secure clear title to the claims, which cover what is said to be one of the richest placer deposits in the country. The average width of the main channel is 150 ft. and the claims cover it for 2300 ft. There is little water available for washing the gravel.

NEW MEXICO

WORK RESUMED AT OLD CARLISLE PROPERTY.

GRANT COUNTY.—The Duncan Mining & Milling Co., Steeplecock mining district, H. E. Spence, manager, has completed a 125-ton milling and cyaniding plant costing \$125,000 to operate on its own ore as well as to handle customs ore from the surrounding mines in the Steeplecock district. The mine is developed by a 300-ft. shaft and has sufficient \$12 to \$20 gold-silver ore blocked out to operate the mill for several months. The old Carlisle mine, which has produced \$6,000,000 in gold and is one of the famous high-grade mines of the South-West, has lately staged a come-back with the discovery between the 300 and 400-ft. levels of what is believed to be the continuation of a high-grade ore-shoot which is said to have netted the original owners about \$3,000,000 when the mines were active 40 years ago. Shipments of gold ore running as high as \$60 per ton are being made to the American Smelting & Refining Co. at El Paso by G. F. Utter and Livingstone Utter, lessees.

The Lone Mountain district, 10 miles south-west of Santa Rita and 4 miles west of Hurley, is showing signs of activity after having been idle for 35 years. Julian Padilla, leasing on claims of Roberts and Betts, is shipping several cars per week of lead-silver ore to the American Smelting & Refining Co.'s plant at El Paso. Placer operations are being resumed on Bear creek in the Pinos Altos district under the management of W. E. Caldwell, who, with associates, has secured control of large areas along the creek. Placer mining has been done in and near Pinos Altos since the discovery of the camp, but this is the first time an attempt has been made to work the deposits in a large and systematic way.

PYRAMID COUNTY. The El Centro Mining & Milling Co. in the Pyramid district has purchased equipment to sink the Last Chance shaft to the 500-ft. level to further develop orebodies which have recently shown well under development on the 275-ft. level.

UTAH

OPHIR CANYON IS BEING PROSPECTED.

GARFIELD.—Fifteen machine-shop workers at the Arthur plant of the Utah Copper Co. quit work on April 17, after submitting a statement that they did not "want to work on unfair castings that are in the shop". It seems that the men involved in the walk-out objected to machining castings that were made in foundries in Salt Lake City which are now on the 'open shop' basis, following a strike some months ago. R. C. Gemmell, general manager, gave out a vigorous statement, to the effect that from its very inception the Utah Copper Co. has maintained a free shop for free men, and has never discriminated between employees because they are or are not

members of any lawful religious, political, or labor organization; that the company has always adhered to an open-shop policy, which has been accepted by the employees of the company, and will continue to do so to the full extent of its ability and resources. Mr. Gemmell further stated that it was his belief that the men who quit did so with great reluctance, and that the walk-out was forced upon them and engineered by outside union organizers of Salt Lake City; that unscrupulous and reckless men, under the guise of labor leadership, are fomenting discord and industrial strife in their efforts to obtain power and control over the men they appoint themselves to represent; to such as these, the 'closed shop' would be a potent weapon, and in their control a menace to every principle of American government and individual liberty.

OPHIR.—Work under way in this camp indicates a big revival of mining, and it is expected that the coming summer will be the most active since the days when millions of dollars worth of ore was mined and smelted here. As a result of the work done during the past eleven months, the geology of the district has been revealed to such an extent that a large area of virgin ground seems available. The orebodies in this district occur as replacements of certain limestones, which are traversed by north-east and north fissures. Most of the output heretofore has come from the mines on Ophir hill, which is on the north side of the canyon. On the south side is what is known as Lion hill. On the property of the Ophir Central, on Lion hill, W. S. Elliott has been driving several diamond-drill holes. It is reported that these holes have been the means of correlating the structure on the two sides of the fault, and it has been determined that the Lion hill side dropped down approximately 600 ft. The Ophir Central company has a hoist, compressor, and other necessary machinery, and in a short time will begin sinking a shaft near the town to open up under Lion hill the lime strata which have been so productive on the opposite side. The largest of the mines on Ophir hill is the Ophir Hill Consolidated, which is owned by W. A. Clark of Montana and to date has paid \$12,000,000 in dividends. Work is being actively carried on at the Ophir Metals property, the tunnel being in a distance of 548 ft. from the portal, and it is expected that the objective limestone will be cut at a distance of 800 ft. The tunnel is now progressing at an average rate of seven feet per day.

PARK CITY.—Entrance of the United States Smelting, Refining & Mining Co. into the district is considered one of the most important events in the history of Park City. This company has taken a bond and lease upon the property of the American Flag Mining Co., which adjoins the Silver King Coalition on the east and the Ontario on the south. At present the United States company is carrying on diamond-drilling work on the 1100-ft. level and following up stringers of ore. In 1903 the American Flag company was organized to develop 22 claims, embracing approximately 300 acres, and since that time has produced in the neighborhood of \$500,000 in high-grade silver-gold ore. The ore contained little or no lead, was of a uni-

formly high grade, with a highly silicious gangue. Based on current prices for silver, the lowest grade ore ever shipped from the property would be worth \$10 per ton; a number of shipments having been made that averaged from 68 to 252 oz. silver per ton, and from 88 80 to \$29 per ton in gold. Since the Ontario drain tunnel lies 210 ft. below the lowest level attained in the American Flag mine, officials of the company believe that difficulties with water will be negligible. The formation is quartzite with two veins, one called the 'Main' and the other the 'Easter', which intersect, both on their dip and their strike. Most of the development work has been done in the Main vein, where a shaft was sunk to a depth of 1060 ft., with a sump 60 ft. below this depth. Approximately a mile of laterals has been run on the different levels.

BRITISH COLUMBIA

'DAYLIGHT SAVING' AT TRAIL

ALICE ARM.—A tunnel has been driven on the Muskeeter claims by A. McGuire for J. D. Mcneach of Seattle. It is reported that this work disclosed some high-class ore. Satisfactory results are said to have been obtained by the diamond-drilling that has been in progress on the Tiger group for some time.

PRINCE RUPERT.—Attention has been drawn by the Prince Rupert Board of Trade to the limonite deposit of the Copper River district situated near Copper City. Reference is made to the coal-fields of that locality, it being claimed that these contain the finest coking coal of the Province. The business men of Prince Rupert fear

SETTLER, SLAG-POT, AND LEAD BLAST-FURNACE AT THE EL PASO SMELTER

On the eleventh level, 60 ft. below the 1000-ft. level, a stratum of limestone about 30 ft. thick was cut. In this stratum, the enrichment, which had been considered excellent in the quartzite, became even stronger, and it was in this bed that some of the best grade of ore was mined.

Notices have been posted by the Silver King Coalition, Ontario, and Daly mines to the effect that beginning April 15, the companies would allow two extra shifts to all employees who work twenty-eight continuous shifts in a month. For some weeks past the Judge Mining & Smelting Co. has had a somewhat similar bonus system in operation. Like all other mining districts in the State, there is a shortage of miners in this camp, and several hundred more miners could be used here. The local mining companies are doing everything possible for the comfort of their employees as a means of keeping them steadily employed.

that the Provincial government and individuals or corporations, in their investigation of the iron and steel possibilities of British Columbia, will overlook these resources, together with the availability of water power and necessary fluxes.

PRINCETON.—The Horn Silver Mining Co., situated in the Similkameen district, is operating again after a period of idleness, weekly shipments of from 45 to 50 tons being sent to the Tacoma smelter. The lessees are working on a vein varying in width from 18 in. to 6 ft., the ore of which contains gold and silver. An aerial tramway carries the ore from the mine to the bunkers whence it is transported by wagon to the railway.

ROSSLAND.—The surface equipment of the White Bear mine was destroyed by fire recently. Flames first were seen bursting from the compressor-house. This soon was destroyed after which the mine-shaft and some unoccu-

piled houses were reduced to ruins. The transformer-house was saved by packing snow about it.

SLOAN CITY.—That a stringer of ore has been opened up on the fifth level of the Ottawa mine, near Sloan City, which assays from 800 to 3000 oz. silver per ton, is reported. The vein was observed during the cleaning out of a drift and it was thought that it contained only about one sack of ore. Development appears to have disproved this and 10 cars already have been taken out, and the vein is now exposed for 20 ft. with a width up to 18 inches.

TRAIL.—The town of Trail, smelter centre of the Consolidated Mining & Smelting Co., proposes introducing 'daylight saving' this summer without regard to what action may be decided upon elsewhere. The company's clocks were set ahead an hour at midnight on April 15. Employees in and around the smelter expressed a preference for this arrangement and the management acquiesced. Ore receipts at the smelter for the week, April 1 to 7, were 4588 tons, making the total for the year to date 77,834 tons. The independent shippers were the Donohue, Nicola, 35 tons; the Emerald, Salmon, 41; the Josie, Rossland, 172; the North Star, Kimberley, 86; the Ptarmigan, Athlamer, 25; and the Spokane Trinket, Ainsworth, 46. The Sullivan mine, Kimberland, contributed 3978 tons of zinc and 205 tons of lead ore.

VANCOUVER.—There is still hope that the Dominion government will establish the long promised ore-testing plant in British Columbia. Some years ago \$300,000 was placed in the estimates to meet the necessary outlay but so far no steps have been taken toward building. Assurance, however, has been received that the money will be re-voted this year and that action may be looked for.

The 'Assayers' Examination Board' has completed a special examination of seven candidates who recently completed a five-month course of study at the British Columbia University under the auspices of the Soldiers' Civil Re-establishment Board. Four were successful and will receive certificates entitling them to practice their profession in British Columbia. They are E. D. Beilby, V. R. Thirkel, T. J. Laing, and F. W. Broughton.

ONTARIO

LABOR CONDITIONS TO IMPROVE IN PORCUPINE.

PORCUPINE.—Since the recent increase in the rate of wages labor conditions have been more satisfactory and harmonious. There is less restlessness among the miners, and a greater disposition to remain steadily at work in place of moving from camp to camp. With the coming of spring the logging season has closed and many engaged in lumber camps during the winter are looking for employment at the mines, which will probably tend to increase production. Diamond-drilling of the Dome Extension has been started by the Dome Mines to determine the extensions of known veins and ascertain whether the orebody developed on Dome Extension on the 600-ft. level continues at depth.

COBALT.—At the annual meeting of the Beaver Con-

solidated on April 15 a dividend of 3% was announced, being the first in two years. Frank L. Culver, president, stated that the company had taken over the Prince property adjoining and that underground development had been begun from the 1400-ft. level of the Beaver. The ore-reserves were estimated at 25,000 tons. The Kerr Lake during March produced 99,400 oz. of silver valued at approximately \$118,286. The company will at once begin treatment of the ore on the dump, amounting to about 80,000 tons, which has been accumulating for some years. The Northern Customs Concentrator Co. is now unwatering the No. 2 shaft of the Chambers-Ferland situated on the section of that property purchased a few months ago. No. 16 vein of the Chambers-Ferland is producing a good quantity of milling ore and some high-grade material. Arrangements are being made to extend the scope of operations on the Genessee. A winze will be put down from the 500-ft. level as it is estimated that the conglomerate formation extends at least 110 ft. downward. The vein on which the winze is to be sunk has a width in some places of from 12 to 15 in. and silver occurs in patches upon the walls and in small stringers which are offshoots of the main vein. The McKinley-Darragh is preparing to resume the pumping of old sand from the bed of Cobalt lake. A considerable quantity of tailing remains to be treated, which is expected to keep the mill in operation all this season and part of next year.

Up to the latter part of April, the silver-producing companies of Northern Ontario continue to withhold their bullion from the market, apparently with the belief that the recession in quotations for commercial bar-silver is but temporary. Milling equipment for the Keeley mine in South Lorrain was transported to the mine before the winter roads broke up, and the management is now free to proceed with the erection without delay.

GOWGAXDA.—The speedy construction of a light narrow-gauge railway from Elk Lake appears assured, as a charter for that purpose has been granted to the Northern Light Railways Co. This will relieve the difficulty under which this district has labored owing to lack of transportation facilities. Leading operators have for some time been endeavoring to induce the Provincial government to construct a standard-gauge railway, but having failed in this will support the other project.

LARDER LAKE.—At the annual meeting of the Associated Goldfields on April 16, G. A. MacKay, president, reported liquid assets in hand amounting to \$1,048,662 and total liabilities of \$11,164. During the year \$169,258 had been spent on development. Diamond-drilling had shown high-grade orebodies at least 500 ft. below the surface, of an average value of \$11.15 per ton. The company is building its first milling unit of 1000 tons daily capacity. A pool exists among the shareholders who were all bound not to dispose of their stock before July 1. The meeting decided to extend the pooling arrangement to 30 days after the mill is in operation and not later than January 1, 1921. H. C. Cooke, formerly with the Canadian Geological Survey, has been engaged as the company's geologist.

COPPER PRODUCTION

The following table shows the output of 18 of the leading copper producers during recent months and also compares the production for the first quarter with that for the same period in 1919. The figures are in pounds.

	March 1920	February 1920	First quarter 1920	First quarter 1919
Anaconda	18,450,000	18,500,000	55,050,000	47,200,000
Phelps Dodge	7,931,000	7,585,000	23,478,000	20,307,733
Uth	8,804,500	9,211,800	29,789,000	29,201,000
Calumet & Hecla	9,880,377	8,600,032	28,131,100	29,022,368
Inspiration	6,500,000	7,200,000	20,900,000	19,800,000
Chino	4,413,329	3,176,489	10,671,755	11,563,676
Miami	5,001,535	1,089,520	13,552,302	11,286,848
Pay Con	3,900,000	3,885,000	11,681,073	12,412,000
Nevada Con	3,700,000	3,850,000	11,731,938	12,200,000
Calumet & Arizona	3,164,000	3,948,000	10,352,000	11,048,000
New Cornelia	3,516,000	3,528,000	10,388,000	9,874,000
Arizona Copper	3,000,000	3,000,000	12,000,000	10,192,000
Old Dominion	2,358,400	2,013,000	6,966,300	7,714,000
East Butte	1,909,720	1,460,300	4,808,000	1,625,740
Granby	2,085,500	2,180,000	6,256,939	6,134,375
Greene Cananea	3,700,000	3,400,000	10,100,000	9,200,000
Cerro de Pasos	5,658,000	4,718,000	14,992,000	15,256,000
North Butte	1,833,176	1,168,509	5,541,745	3,907,033
Total	95,905,633	92,254,736	283,398,223	271,376,703

ALASKA

Juneau.—Charles Hayden, president of the Alaska Gold Mines, is quoted as saying: "The company can continue operation only so long as advantage can be taken of extracting ore already broken in stopes or prepared for mining, on which development and breaking costs have been previously paid either wholly, or in large part, thereby recovering the amount invested in the development and preparation for mining of such ore-reserves." The gold recovery last year decreased from 88c. to 66c. per ton as compared with the previous year, and there seems to be a question whether there is profit to be obtained even under a more favorable condition of the market for labor and supplies.

ARIZONA

Jerome.—The town where is situated the U. V. X. smelter is hereafter to be called Clemenceau. It was decided that Verde was confusing, as there was an old postoffice in the same valley by the name of Fort Verde. James S. Douglas, president of the Extension company, is said to have selected the new name, having in mind his overseas experience in the Red Cross at the Paris depot.

Phoenix.—The Arizona Cave Creek Mines Co. has recently been formed by A. S. Lewis, of Phoenix. The company is backed by prominent Rochester and Buffalo capitalists. The company will take over promising prospects in the Cave Creek district and develop them.

Pima County.—Percy Williams, general manager for the El Tirol Leasing Co., reports that ore is now being stoped at four places on the 200-ft. level, averaging better than 8%. Stope No. 4, with over 200 ft. of virgin ground overhead, is furnishing nearly one-half car per day of 7% ore. Certain portions of this new stope for eight feet in width average more than 10% copper. During March, 29 cars of ore were shipped, totaling 1457 dry tons, averaging 8.04% copper, which was sold at an average price of 18.28c. per pound. Four cars of this ore were produced by sub-lessees working at various points on the surface where there is enrichment.

Tucson. B. Hatcher, of the assaying firm of Andrus & Hatcher of Tucson, has taken charge of the Roadside mine, 50 miles south-west of Tucson, for the Huntington interests of Los Angeles. A new shaft will be sunk, as the old shaft is in bad condition.

Yavapai County. W. E. Plank is drilling some placer ground near the old Rich Hill diggings. He has a full crew at work, and so far his returns have been encouraging.

CALIFORNIA

Amador County.—Arrangements have been made for re-opening of the Fremont Consolidated mine under new management. Repairs are being made to the surface plant and the pumps will soon commence unwatering the old workings.

—The Garibaldi is yielding high-grade ore and is to be developed on a greater scale.—Representatives of outside capital are investigating the Drytown Consolidated and Crown Point mines with a view to their rehabilitation, according to advices.

Plumas County.—The discovery of copper carbonate in the drift left of the main tunnel is reported from the Feather River group. This ore was cut about 610 ft. from the tunnel-portal. The company recently ordered additional equipment.—Operations are in progress at the Engels, Walker, Gruss, Beardsley, Trask & Coffer, and other copper properties in the Plumas field, which is now the foremost producer of copper in California. Despite the high cost of labor and material and the unfavorable market operations in the Plumas field are active.

IDAHO

Boundary County.—At the Idaho-Continental mine, near Porthill, milling operations will be resumed as soon as a force can be assembled, according to A. Klockmann, general manager. Water is flowing in sufficient volume for the generation of power. Approximately 30,000 tons of ore is broken in the mine and the ore in sight is sufficient for one and a half to two years of milling. All of the concentrated ore on hand was hauled during the winter.

Coeur d'Alene.—H. E. Owen, of Spokane, head of the Wardner Leasing Co., has obtained an option for two years on the property of the Slavonian Mining Co. and the Petronivich claims having an area of 160 acres at Wardner. Included in the Petronivich claims is the Butler, from which high-grade ore was shipped.—The Caledonia Mining Co. has declared its regular dividend of \$26,000. This is at the rate of one cent per share on the issue of 2,605,000 shares. The disbursement, which will be made May 5, will raise the total dividends to \$4,063,800.—The Nabob Consolidated Mining Co. has plans for the installation of equipment for saving the zinc in its ore. The value of the zinc passing through the mill is estimated at \$300 per day. An important saving is anticipated from a new electric-haulage system in the lower tunnel.

The present board of the Hecla Mining Co. was re-elected at the annual meeting at Spokane recently. James F. McCarthy is president, treasurer, and manager. The board of directors has authorized the disbursement of an extra dividend of \$50,000 at the time of the regular quarterly disbursement of \$150,000 in June, making the total payment

\$200,000 or 20c. per share on the issue of 1,000,000 shares. The forthcoming payment will increase the grand total of dividends to \$8,205,000. The company is hoisting 750 tons daily. About 600 tons of this is passed into the mill, the remainder being waste and shipping ore. The quantity of material hoisted is greater than at this period a year ago, but less than that of a corresponding period two years ago. Shipments are being made at the rate of 100 tons per day.

MISSOURI

Joplin.—The Bethlehem Zinc Co., which several years ago developed a lease one mile east of Quapaw, which was worked with some success, now is opening a lease near Treece, Kansas, that promises to be as successful as other mines of that district. The lease contains fifty-five acres on the Wright land and is next south of the Silver Fox mine. All the ground has been thoroughly drilled and a shaft has been sunk into ore, which is found at 250 ft. The drilling proved high-grade ore in a large part of the lease. The shaft is in ore that runs 25% zinc. The company will move its mill from the lease of the Quapaw to the new lease and will push the work as rapidly as possible. The mill is of 300 tons capacity and is in good condition. Herman B. Jones, of Joplin, is manager.

The Prospectors Development Co., whose property is just south of the Blue Bonnett mine at Hockerville, has seven drill-rigs at work testing its forty-acre lease. Eighteen holes have been drilled and it is said good ore has recently been found. The company has a 150-ton mill in operation, but for several months has run the plant only enough to make expenses of operating, as there has been a shortage of water for milling purposes and there have been a number of changes under way. It seems that the Blue Bonnett found more than enough water at 250 ft. and plants of the St. Louis company, adjoining the Prospectors lease, found too much water at less than 200 ft., but the Prospectors have never had as much water as it wanted, although it has sunk to 265 ft. J. D. Simpson is president.

NEVADA

Goodsprings.—The downward extension of the orebody which has produced so well for the Yellow Pine Mining Co. has been cut on the 1000-ft. level, 600 ft. north of the shaft, at a point near where the dip and rake of the shoot on the level above indicated it would be found.

At the Yellow Pine mill the U. S. Bureau of Mines men have been carrying on volatilization tests, with the idea of driving off silver and lead and precipitating the same from the fume by the Cottrell process. The tests were made in a calcining furnace 60 ft. long and 5 ft. diameter, which is used for driving off moisture and carbon dioxide and thus decreasing the weight of the ore in proportion to the amount of these elements present. This is believed to be the first time that the Bureau of Mines men have had the opportunity to work on this kind of experiment on a commercial scale. The results obtained are said to have been highly satisfactory, after some changes were made in pressure employed in the fuel burner.

Obituary

George Schroter Patterson was accidentally killed on April 14 at the zinc mine of the Northern Ore Co., at Edwards, New York. He was born at Denver, Colorado, on October 9, 1892, and graduated from the Denver High-School and from Columbia University School of Mines, in the class of 1914, receiving the degree of Engineer of Mines. For two years he was at the Franklin Furnace mines of the New Jersey Zinc Co., in the capacity of surveyor, shift-boss, etc. In 1916 he was appointed mine superintendent for the Northern Ore Co. and general manager for the same company just previous to his death.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Charles Butters is at Mazatlan.

Arthur W. Jenks has returned from New York.

James S. Douglas has returned from New York to Bisbee.

Walter Eltch, Jr., mining contractor of Eureka, Utah, is in Pennsylvania.

W. S. Van Dyck has moved from San Jose, California, to Unionville, Nevada.

A. W. Allen left New York for Chile on April 21, expecting to be away for six months.

J. H. Wolf has returned from Korea, where he was in the service of the Seoul Mining Co.

James C. Ray has returned to Palo Alto from the old silver district south of Austin, Nevada.

O. M. Kuchs, general manager for the International Smelting Co., of Salt Lake City, is in New York.

R. A. Brown has been appointed consulting engineer for the Michigan Utah Con. Mines Co. at Alta, Utah.

Karl Kithil has returned to Denver after investigating the new radium discovery in Grant county, New Mexico.

J. Power Hutchins arrived in New York on March 12 and sailed again for London on his way to Italy on April 24.

Jules Labarthe has resigned as a director of the Bunker Hill company, his place being taken by **Frank M. Smith**.

A. E. Robinson has left the Utah Con. Mining Co. to take charge of the Hidden Treasure mine at Lake City, Colorado.

H. C. Goodrich, chief engineer of the Utah Copper Co., has returned to Salt Lake City after a trip to Duluth and Chicago.

R. K. Neill has resigned as manager of the Premier mine, in the Salmon River district, B. C., and is succeeded by **Dale L. Pitt**, his assistant.

H. V. Winchell was in Salt Lake City recently. On April 26 he addressed the 'Hoover for President' Club at a luncheon given at the Newhouse hotel.

Albert Burch has been appointed manager for the Simon Silver-Lead Mines Co., at Mina, Nevada. Previously he was consulting engineer to this company.

John Hay, Jr., has been appointed consulting engineer to the Pioche Mines Co., having assumed the position made vacant by the death of **Oscar A. Knox**.

Norman W. Haire has resigned as general manager for the Michigan Utah Con. Mines Co. at Alta, Utah. **Nicholas A. Robertson** has been chosen to succeed him.

H. G. S. Anderson, assistant general manager for the Chino Copper Co. at Hurley, New Mexico, was married on April 8 to Miss Mary McCrae, at Rolla, Missouri.

John V. Richards, of Spokane, Washington, having resigned his commission as Major in the United States Army, is manager for the Wilshire Bishop Creek Mine, at Bishop, California.

D. W. Leeke, on his return from the west coast of Mexico, sailed, on April 23, for the Philippines, having accepted an appointment as engineer on the staff of the Benguet Consolidated Mining Co.

H. Trencar Thomas, metallurgical engineer to the Ooregum Gold Mining Co. of India, has been visiting our Western mining districts and left San Francisco on his return to London on April 28.

Victor C. Alderson, president of the Colorado School of Mines, will sail on May 19 from New York to England. While abroad he will visit the shale districts in Scotland and France, inspecting recent discoveries and methods of extraction.

Zinc-dust, cents per pound.....	12 50-15 00

EASTERN METAL MARKET

(By wire from New York)

April 26.—Copper is inactive but steady. Lead is quiet and easier. Zinc is dull and lower.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46 65 pence per ounce (925 fine), calculated at the normal rate of exchange.

				Dec.	115.00	95.00

In its current publication on the financial situation, the National City Bank says:

The whole credit situation was helped sentimentally by the announcement that the British and French governments would pay the \$500,000,000 loan which will become due in October next. It was a moral tonic which had immediate effects. Proof that these countries were not bankrupt was hardly necessary, but sentiment in the exchange and investment markets had been dependent to a degree that required a cheerful surprise of this kind to dispel the prevailing pessimism. The announcement had that effect for several reasons, the most influential of which, perhaps, was the promise that a considerable amount of gold would be forthcoming which would serve to replenish our reserves and make good the losses which we have seemed destined to suffer by exportation to Argentina and Asia.

The gold situation was on everybody's nerves March 1, and we discussed it at some length in the March letter. The excess of gold exports over imports in January was \$35,740,487, and in February \$38,557,000, a total since January 1 of \$74,297,487, and the margin of excess reserves in the Federal Reserve system was so narrow as to arouse misgivings that more drastic action might be taken by the authorities for the reduction of loans. The announcement that the loan would be paid, together with a rumor that gold shipments would begin at an early day, instantly relaxed the tension. At about the same time, the demand for gold on account of India eased off in London to such an extent that two lots aggregating about \$3,000,000 were obtained for the United States, and another \$3,000,000 came in from Canada.

It still remains to be developed how much gold will come in payment for the Anglo-French loan. It is known that the British government has been accumulating credits here by the sale of American securities and Australian wool, and has been buying the Anglo-French notes in the open market. Probably its share of the loan will be largely cared for in that way. It is not so clear how the French government will take care of its half of the undertaking, but special efforts have been made to bring in the last installment, and have aggregated a considerable amount. The first installment on the gold payments, approximately \$9,000,000, arrived on March 25. The fact that shipments have begun so early indicates that the total amount is expected to be a large sum.

The most that can be said for this promise of gold is that it relieves to some extent the anxiety as to diminishing reserves. It affords no reason for expecting a renewal of credit expansion. The Federal Reserve authorities have been moving cautiously in this country, and the reserve banks from war-paper and retting those institutions back into normal condition, but there is no reason to doubt that they are firm in the purpose. Whatever gold is received will be all needed to provide against the exports which must be kept up, and it would be very short-sighted to modify the loan policy which has been adopted. With the credit expansion of the last year as a warning, and the revelations which are being made of speculative investments by means of bank credit in sections of the country where the liquidation might have been rapidly accomplished, it is plain that for the good of the country the situation should be held firmly in hand. The country should be urged to pay its debts and practice for a time the old-fashioned policy of earning and accumulating before spending or investing.

Eastern Metal Market

New York, April 21.

Buying of all metals has been held up by the railroad strike and the markets are all very quiet. There has been some decline in prices.

Demand for copper is exceedingly light from domestic sources but prices are only slightly changed.

The tin market is very quiet and buying has been negligible. Prices continue fairly high.

Lead prices have declined in the outside market.

Buying of zinc continues insignificant and prices are lower.

There is little change in antimony.

IRON AND STEEL

While the end of the railroad strike is in sight the delivery of steel products is seriously disorganized and the return to normal conditions is not expected for a good many days, says 'The Iron Age'. Buying has been much curtailed in the past week and manufacturing consumers of pig-iron and of rolled steel have been compelled in many cases to shut down wholly or in part because their fuel supply was cut off.

Weakness in steel plates, long predicted because of the large producing capacity, is not much in evidence. Two more British shipyards have been buyers, both at 4c., Pittsburgh, one for 7500 tons and the other for 2000 tons, with 19,000 tons additional in the latter case yet to be placed.

COPPER

There is almost an entire absence of buying of electrolytic copper. Demand a week ago was noted as having fallen off and this tendency has been greatly intensified by the railroad strikes which have interfered with shipments from mines to smelters and from smelters to refineries, to say nothing of shipments to consumers. This is true of all the metals in a greater or less degree. The large producers are firm in their quotations for electrolytic copper of 19 to 19.25c., New York, for early delivery. For June a slight premium is the rule and for third quarter a decided disinclination to quote at all except where necessary, in which case about 19.50 to 19.75c. is asked. In view of the heavy buying a few weeks ago demand is necessarily light from domestic consumers. Buying for export to Germany, France, England, Switzerland, and other countries is exceedingly good and last week exports of copper were 1525 tons to France, with Germany second at 1185 tons. Lake copper is quoted at 19.25c., New York, for April-May delivery, at which level a good sized order was sold late last week. A premium is obtainable for forward shipments.

TIN

The market has been and is exceedingly quiet and no business has been done for some days. Prices have maintained a fairly high level, due to the continued high quotations in the London market. This fact, together with the railroad strikes, has influenced consumers to remain out of the market. They have at no time been buyers except when prices receded. They also recognize that it is no use to buy what cannot be shipped. Yesterday spot Straits was quoted at 62.25c., New York. The London market was strong at £349 10s. for spot Straits. This is about £3 higher than a week ago. Late last week there were a few sales of April-May and May-June shipment from the East at around 61c. When the general situation clears up a better demand is confidently expected. Arrivals thus far this month have been 1279 tons, with 3691 tons reported afloat.

LEAD

The strength that was noted a week ago has disappeared. While buying has abated because of railroad strikes, tend-

ing to weaken the market, this situation was aggravated by the sudden offering late last week of metal at 8.50c., St. Louis, by a large independent interest. This knocked the props from under the market and no recovery has taken place since. We quote the outside market at 8.50c., St. Louis, or 8.85c., New York, with the leading interest's prices unchanged at 9c., St. Louis, or 9.25c., New York. As soon as the situation rights itself and a recovery from the strike has set in, a higher market is predicted. It is almost impossible to buy a carload of lead in New York because so much metal is held up in transit. For small lots a substantial premium has been paid.

ZINC

The stagnation in this market continues. It has been aggravated if anything by the strike epidemic and prices are lower. Prime Western for early and second quarter delivery has been steadily declining and yesterday was quoted at 8.15c., St. Louis, or 8.50c., New York, with the possibility of 8c. at St. Louis. The weakness has also been accentuated by the continued selling here by British exporters of metal bought here and repurchasable on the other side at lower levels. London markets continue to decline also. Leading producers are uninterested in present prices and are doing very little business. Export business is also quiescent.

ANTIMONY

The market is quiet with Asiatic metal in wholesale lots for early delivery quoted at 11c., New York, duty paid, for the better grades and 10.75c. for the other. There is considerable conjecture as to what effect the industrial situation in Japan will have on the market.

ALUMINUM

Prices are unchanged at 33c. per lb., New York, for wholesale lots for early delivery of virgin metal, from the leading producer, with 31c. asked by outside interests.

ORES

Tungsten: Prices are firmer with low-grade ores at a minimum of \$7 per unit, but there is very little business. In this market strikes also have had their dampening effect. This, together with the uncertainty regarding the tariff, has made for a dull uninteresting market.

Ferro-tungsten is quiet and unchanged at 90c. to \$1.15 per lb. of contained tungsten. It is interesting to note that, according to official statistics, imports of ferro-tungsten and tungsten metal as powder for 1919 have been 396,460 lb. of which 340,964 lb. came in during the last quarter. During the War these imports were negligible, the exports predominating.

Molybdenum: The market is inactive and prices are nominal at 75c. per lb. of MoS₂ in regular concentrates.

Manganese: Quotations are unchanged at 65 to 80c. per unit, seaboard, for foreign ore, depending on the delivery. Advices from England are that a scarcity of tonnage is handicapping importers and that supplies in India are limited. The price for Indian ore is up to 4s. per unit, delivered British ports. This is about the same as the price at American seaboard at the present rate of exchange, 80c. having been paid here for early delivery.

Manganese-Iron Alloys: Prices are unchanged for ferro-manganese at \$200, delivered, for the American alloy for last half and \$195, seaboard, for a limited quantity of British alloy for shipment during August and later. Sales of small lots are recorded. The spot and early delivery price is unchanged at \$225 to \$250, the former applying to small lots of British alloy and the other to American, with sales of small lots reported. Spiegeleisen is higher at \$75, furnace, as a minimum with demand moderate.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A NEW DRILL-STEEL SHARPENER

A new drill-steel sharpener operated by compressed air known as the I-R No. 50 has been developed by the Ingersoll-Rand Co. This machine embodies a number of new and distinctive features, some of which are outlined below.

This sharpener was designed primarily to sharpen and shank rapidly and exactly drill-steel such as cruciform steel up to 2 in. diameter, or round, hexagon, octagon, quarter-octagon, auger, or spiral steel up to 1½ in. diameter. However, it has performed so many other tasks that 'drill-steel sharpener' is almost a misnomer. When fitted with special devices, it will forge bolt-heads, pins, stanchions, etc., in

Sufficient attention has not been given to this in the past with the result that breakage was too common. A glance at the accompanying illustration will show how substantial and rigid is the base. It needs absolutely no foundation with the exception of a few planks to level it properly and is not even bolted rigidly to them.

Poor lubrication is due most frequently to the ordinary exposed sight-feed lubricator's being accidentally damaged or broken. The No. 50 sharpener has no sight-feed or other exposed lubricators. Efficient and positive lubrication is provided for the entire machine by the Ingersoll-Rand 'Heartbeat' lubricator. This is embodied in the throttle valve-chest casting and works automatically whenever the machine is in action. It is provided with adjustment for regulating the quantity of oil desired. This same idea is carried out throughout the entire machine. Every part is made for long, hard, continuous service. An example of this is the absolute elimination of all cup-leathers. Only accurately machined snap piston-rings are used. This will mean much to any man who has ever used a sharpener.

Ingersoll-Rand Drill-Steel Sharpener

fact, nearly 200 different products have been made by this machine.

The single lever, which controls all of the operations of the machine, is fitted with a safety locking device. This prevents accidents because it is impossible to operate the machine unless the lock is released. The throttle-valve is of the balanced-spool type, operates easily and quickly, and is positive and instantaneous in its action.

The hammer-cylinder is an improved valveless type. This construction permits the free moving hammer to deliver exceedingly fast and powerful blows against the end of the dolly upsetting the steel and so forming the bits and shanks with extreme rapidity. This may be more easily understood when it is mentioned that its capacity is about 20% greater than the Leyner No. 5 sharpener.

The base must have sufficient strength to withstand the severe strains and shocks met with in its everyday work.

IMPORTANT COMBINATION OF TWO LARGE ENGINEERING AND CONSTRUCTION COMPANIES

Of general interest is the combination recently announced of the organizations of Westinghouse, Church, Kerr & Co., engineers and constructors, and Dwight P. Robinson & Co., constructing and consulting engineers, both of New York. The new company will be called Dwight P. Robinson & Co., Inc., and will occupy executive offices at 61 Broadway and engineering and designing offices in the Grand Central Palace, 125 East 46th street.

Dwight P. Robinson, president of the new company, was for many years president of the Stone & Webster Engineering Corporation, and formed his own company in 1918. He has had an unusually valuable experience in the design and construction of industrial plants, large central power-stations, and hydro-electric plants, and his company has specialized in work of this nature. At the time of the merger the Robinson company had large power-plants under construction for the Duquesne Light Co. at Pittsburgh, and the Penn Public Service Co. at Johnstown, Pa. Westinghouse, Church, Kerr & Co. was established thirty-six years ago, and has specialized in the design and construction of industrial plants of all kinds, railroad shops and terminals, and industrial power-plants.

The Westinghouse Electric & Manufacturing Co. is one of the largest stockholders of Westinghouse, Church, Kerr & Co., and the two companies have been closely identified for many years. To avoid what has seemed a handicap in procuring business by the latter company, on account of the belief of prospective clients that if they employed it as their engineer, they might be expected to purchase Westinghouse equipment; and also to permit the Westinghouse Electric & Manufacturing Co. to withdraw from any interest in the engineering and construction business, that being a field foreign to its normal activities, it was deemed in the interest of both companies that the above association should be

terminated. To accomplish this without embarrassment to other stockholders, and to their advantage, negotiations were initiated with Dwight P. Robinson, president of the Robinson company, looking to a merger. These negotiations resulted in the plan now declared operative, under which depositing stockholders will receive for their present holdings either cash or stock in the new company. It is believed that the new organization will become one of the largest and most successful in the construction and engineering business.

CUTTING WIRE ROPE

Proper provision for the protection of human life in mines demands frequent and regular inspection of hoisting cables by responsible persons and the employment of approved processes in effecting needed repairs. A section devoted to 'hoisting ropes' in the draft of a law to cover mine rules and regulations, proposed by the United States Bureau of Mines, is evidence of the extent to which the cutting of wire rope is now required in the maintenance of mine equipment.

The approved method of cutting the rope preparatory to re-socketing and re-clamping is the well-known oxy-acetylene process. There is no simpler or easier way. A typical outfit that has been found dependable comprises a standard 'Oxweld' cutting blow-pipe, a Linde oxygen cylinder, and a tank of 'Prest-O-Lite' dissolved acetylene. With this equipment a competent operator cuts through a two-inch cable in just about two minutes. The cutting apparatus is portable, so that it may be easily set up anywhere at a moment's notice.

The saving in time and expense in the cutting of rope may very profitably be extended to discarded rope, which may be reduced to lengths for use in other ways. By adding the welding blow-pipe to the equipment noted above the mine is provided a complete outfit for the speedy repair of broken machinery, making it unnecessary to depend on machine-shop repairs or costly replacements.

FREE TRIPS TO SULLIVAN PLANTS

By S. B. King

Hundreds of mining and engineering school students in all parts of the United States are being taken on trips to the Sullivan Machinery Co.'s plants in Claremont, New Hampshire, and in Chicago so that they may see just how drills, coal-cutters, air-compressors, and drill-sharpener machines are made. This summer thousands of miners and engineers, who have been using Sullivan machines, will make the same excursion, to view the 'home life' of their mechanical friends. The students, engineers, and workmen will be Sullivan guests, the company to bear all expenses. And it will not cost Sullivan company so very much because the guests all make the trip via the 'Film Rapid Transit'.

The Sullivan company believed workers and engineers would have an even greater appreciation of Sullivan machines if they could be shown where and just how the machines are made. It being impossible to get the thousands of men to the plant, it was decided to place the plants aboard the celluloid magic carpet and take the industries around to the men.

The Sullivan picture opens with panoramic views of the Claremont and Chicago works. The movie audience then visits the interior of the Claremont foundry and sees the pouring of air-compressor castings. The air-compressors, made at both the Claremont and Chicago plants, are then followed through the various stages of machining, assembly, erection, and the final testing at full speed and load before shipment. Interesting details include the gigantic planer at Chicago on which twelve angle-compound compressor frames are planed at one operation; the assembling of water valves and of finger valves used in the different compressors; and

the steam-valve action on one of the company's 2500 Corliss compound air-compressor in which the operation of the Corliss valve-gear is clearly shown.

The second part of the picture is entitled 'How Hammer Drills are Made'. The fact is emphasized that the company's rotators, water-drifters, stopers, etc., are made not from castings but from solid billets of steel or from steel bars. The observer is shown the wonderful automatic machinery by which the different parts are milled, shaped, and ground to the exact sizes and close fits needed in this class of machinery. Materials are shown under test in the company's chemical and physical laboratories and also in the carbonizing and heat-treating department, in which rows of furnaces, flanked by quenching-baths of different liquids and at different temperatures, give the parts of the drills the necessary hardness and toughness (to resist the terrific strain of pounding upon rock. This section of the film is completed by a trip to the company's quarries or proving grounds, where the completed machines are tested for air consumption and drilling speed under actual service conditions. Complete views are shown of the company's drill-sharpening machine and drill-heating furnaces for the better care and treatment of the drill-steel used in mining.

THE SMALLEST MINE LOCOMOTIVE

It is common occurrence for us to hear about exceptionally large sizes of things, while the 'largest ever built' is a familiar phrase. An article in a recent number of the 'General Electric Review' tends in the opposite direction and describes the smallest practical mine locomotive ever constructed. This locomotive was designed for underground service and to meet unusual conditions in mine-development work. It is rated at two tons, for operation on 20-in. gauge track, and at three miles per hour has an effective drawbar pull of 400 lb. Overall it measures 43 in. long, 34 in. wide, and 35 in. high, with a removable step and operators seat so that it can be run on a cage and hoisted and lowered to the different mine workings as the occasion requires. The two trailer trucks carrying the batteries are likewise of small dimensions. Two are required so that the locomotive can operate continuously, each of the trucks being equipped with 55 cells of type A-4 Edison storage batteries.

The locomotive is operating satisfactorily at the Real del Monte Rosario mine in Mexico. A special feature of this locomotive is the adaption to it of a motor which renders feasible the use of a single reduction gear-drive. The saving of energy in the elimination of gears, pinions, countershafts, etc., gives the locomotive a much greater radius of action on each charge of the battery.

COMMERCIAL PARAGRAPHS

The Erection Department of the Kansas City Structural Steel Co. has established camp at Avondale, Louisiana, preparatory to the erection of four 55,000-bbl. tanks for the Export Oil Corporation of Tulsa, Oklahoma.

The manufacturing and selling of Delco-Light products heretofore conducted by the Domestic Engineering Co. has been transferred to the General Motors Corporation, and will be operated under the name of 'Delco-Light Company'.

The Aldrich Pump Co., in 'Pump Data No. 52', points out a number of advantages in using its flexible-disc coupling for operating pumps and air-compressors. A coupling of this type absorbs the shock incident to starting and stopping, and to irregularities in the operating load. The Aldrich coupling is universal in its application, and is designed to take up any non-alignment in the setting of the motor, and thereby relieve gearing and motor from jar and vibration.

T. A. RICKARD, . . . Editor

LIBERAL estimates by the U. S. Geological Survey place the world's production of coal in 1919 at 1170 million metric tons of 2205 pounds, which is the smallest output since 1910. The record year was 1913, when 1341 million tons, or 6.8% more than in 1919, was mined. Data on the production in the principal belligerent countries, which together contribute 85% of the total, show a decrease of nearly 30% in Europe as compared with only about 4.5% in the United States. Approximately 40% of the total supply comes from the mines of our own country.

WHAT the premium on gold has done for South African mining shares is indicated by a few quotations, the first figure being that of April 14 last year and the other the highest recent quotation: Central Mining, 8½, 12¼; Crown Mines, 2½, 4½; Rand Mines, 2½, 5; East Rand, 5s. 9d., 18s. 6d. Incidentally, the fall in French exchange, together with the premium on gold in London, has stimulated selling from Paris, because, for example, Rand Mines shares were worth 84 francs a year ago and are worth 200 francs now. The German holdings were sequestered during the War.

GENERAL WOOD is a good soldier and an excellent citizen; all the more pity that the name and photograph of his son, Leonard Wood, Jr., described as "a chip of the old block and a go-getter with a record", should be used on an advertisement of an oil wild-cat in Texas. Another military officer's name is attached to the prospectus. Such commercializing by young men of an honorable name and an equally honorable record in the War is deplorable. The promoters of the Craven Oil & Refining Company may be 'go-getters', but they have a great deal of taste and it is all bad. Captains Craven and Wood will be well advised to cease exploiting their military records, or their family names, in such business.

FOREIGN trade with the United States continues to expand. During the first quarter of this year the total of our imports was at the rate of \$5,700,000,000 per annum, as compared with the annual average of \$1,160,000,000 in the decade ending with 1910. Moreover, our export business is increasing, despite the check placed upon it by the collapse of foreign exchange. In March our exports amounted to 820 million dollars as against 603 millions in the corresponding month of last year;

imports were worth 184 millions as against 267 millions a year ago; thus the so-called balance of trade was 436 millions, as against 336 millions in March 1919. This is a surprising and most agreeable result, having regard to the present unsettled economic conditions. At the current rate our foreign commerce this year will amount to 14 billion dollars.

PROGRESS is being made in the campaign for legislation to establish a National Public Works Department. A joint resolution has been introduced in Congress providing for the appointment of a committee of three from each branch of Congress to make a survey of the administrative services of the Government and to determine what re-distribution of activities should be made, so that each executive department shall embrace only those services that are closely related; and to prepare bills and resolutions having for their purpose the co-ordination of the functions of government, and its efficient and economical conduct. The response of the country to the propaganda in favor of a National Public Works Department has been such as to render members of both houses of Congress willing to accede to this preliminary investigation.

ON another page we publish an article describing the troubles brought upon the mining industry in Siberia by Bolshevik disorder. The writer, Mr. R. G. Knickerbocker, is manager for the Messina copper-mining enterprise in the Transvaal. At one time he was Assistant Professor of Metallurgy in the University of Cincinnati. Incidentally Mr. Knickerbocker gives many interesting details of technical practice at Kyshtim, including the use of producer-gas, the electrolytic refining of copper, and the employment of oil-burners in the doré furnaces. The impact of bolshevism upon a well organized and highly important industrial establishment is told in plain words, more eloquent than any rhetorical argument. To this is added a recital of Mr. Knickerbocker's personal experience amid the topsy-turvy conditions of Russian misrule.

CLEVER people sometimes do foolish things. For example, the supporters of the McFadden bill for granting a bounty on new gold are making a mistake in giving wide publicity to their so-called gold dinner, to which a number of rich men have subscribed. A hysterical evening newspaper in San Francisco has been pub-

lishing daily a list of subscribers to this affair. They consist of bank presidents, financiers, and rich mine promoters. One or two mining engineers are included, and we venture to express surprise at their willingness to endorse the scheme, for they ought to know that if the proposed legislation is to be pushed thus, apparently by the *haute finance*, it will not receive public support, because the stamp of class legislation will be placed upon it. Two reasons exist for supporting the McFadden bill: first, it will aid an honorable and old industry now crippled by adverse conditions; second, it will protect the gold reserve of the United States. The less splash the wealthy part of the community makes at this juncture, the better it will be for those directly interested in gold mining.

WONDERS never cease! At Kremmling, in Colorado, there have been found no less than "thirteen minerals, including alumina", so we are told in a 'special' to the Denver 'News', the mining editor of which is a trustee of the State School of Mines. What is even more remarkable is the statement that "alumina has never before been found in Grand county". Then the name of the county should be changed to Non-Mineral, in contrast to the existing Mineral county, made famous by Creede. "The analysis of the ore shows the alumina content to be 7.22%, worth \$25", but it is remarked that "the extraction process is said to be too expensive to justify working the ore for the metal at present". Hence the question, is it an 'ore'? It seems to us to be a mediocre portion of the earth's crust, suitable possibly for road-making. Besides alumina, it contains "gold, silver, copper, titanium oxide, iron oxide, manganese, magnesia, potash, zinc and soda". Why not whiskey and soda or something equally and archaically exhilarating? It is a sad and dry world, when we are given soda in which the 'stick' is zinc and magnesia and other effervescent piffle.

TO prove the need for a law compelling the licensing of engineers, a correspondent sends us an account of the Redondo oilfield by a gentleman who claims to be a geologist. However, a geologist is not an engineer, although some engineers are geologists. Evidently the geologists likewise must be licensed and registered and disciplined in the public interest. The Californian gentleman under fire found "skeletons of what was at one time coral reefs overlying the strike of the fault", which is much like putting a heavy weight on the angle of the parallax; or tying the meridian to the exhaust of a motor-car. Next, our pseudo-scientific friend found "conglomerate on the hills that are of a volcanic origin deposited at a time that part was submerged", which suggests cataclysmic conditions of a fearsome kind. He worked along the beach, beside the sad sea-waves, "to find the stratification which is dipping north" and he "also found a very rich strata of manganese". How singular, and yet how plural! He saw signs of oil and believes that "gas will be found in paying quantities at a shallow depth". So do we; it will be found right on the surface and it will come through an orifice lined with white pro-

jections of an osseous nature belonging to a biped of ruminating character.

SOME features of the present condition of the fuel-oil industry in its country-wide aspect are reflected in a statement of the Standard Oil Company, to the State Railroad Commission, apropos of its recent announcement of increases in price. The price offered for 'fuel crude' at the well has been raised from \$1.23 to \$1.48, simultaneously with an advance from \$1.60 to \$1.85 to the consumer. The statement specifically declares that need for additional revenue did not enter into the decision to increase rates. While we scarcely credit the Standard with viewing the additional income with distaste, we do think that it is sincere in its statement that the motives behind the advance are to stimulate increased production and to conserve the supply by limiting the use of fuel-oil. Since May 1915 the stocks of crude oil in California have decreased from more than 60,000,000 to 28,738,921 barrels on March 1, 1920. Of this less than 13,000,000 barrels is available today. At the present rate of consumption the surplus will have vanished in twelve months and the current supply will then automatically be diminished by 25,000 barrels per day. Conditions affecting the economy of oil are much the same throughout the country. The apparent remedy is the use of coal where it will serve the purpose, and intensive development of further oil resources.

A SIXTH member-society has become associated with Engineering Council, namely, the American Railway Engineering Association. The other members are the national organizations of civil, mechanical, mining, and electrical engineers, and the American Society for Testing Materials. The Association has 1650 members, so that the aggregate membership of the organizations represented on Engineering Council is now 45,000. Mr. Harry R. Safford, president of the American Railway Engineering Association and assistant to Mr. Hale Holden, president of the Burlington and allied railroads, will represent the newly affiliated society on the Council. Evidently Engineering Council is destined to fulfil the dream of a nation-wide organization of the engineering profession. We note that the Joint Conference Committee of the four founder societies in the Engineering building, New York, has issued a call to the engineering societies of the United States to assemble in an organizing conference to be held at Washington on June 3 and 4, pursuant to a resolution to that effect passed on January 23 at a joint meeting of the governing boards of the four founder societies and of the American Society for Testing Materials, as well as of the trustees of the United Engineering Society and the members of Engineering Council. The object of this convention is to promote co-operation between the various societies with a view to furthering the public welfare wherever technical knowledge and engineering training are involved. It is hoped to establish a national association of engineering organizations by means of a representative national council.

The Moralities of Journalism

During the present political campaign there has arisen question as to the conduct of newspapers in regard to the publication of matter coming from the party to which they are opposed. It is absurd to suppose that our local papers have any moral code answering to the term 'ethics', but it would appear that even a press so debauched as that of San Francisco has qualms as to the proper thing to do in certain contingencies. For example, the Hoover Republican Club sent an advertisement to the two morning papers. The 'Examiner' printed it and was paid for it. The 'Chronicle' declined to print it, because forsooth it was a 'vilification' of its candidate, Senator Johnson. As a matter of fact it was a comparison of the records of the two candidates opposed to each other in the Californian primary election and contained nothing more than might be expected as propaganda from the side that submitted the advertisement in the usual way. The sensitiveness of the 'Chronicle' is amusing when we recall the fact that Senator Johnson said of its proprietor in 1916: "When there is a city to be pillaged, when there is a community to be robbed, when there is a man to be stabbed in the back, always lurking in the background can be found Michael Henri De Young." Next, it is claimed by the followers of Senator Johnson that the 'Bulletin', an evening paper supporting Mr. Hoover, "suppressed an entire article written by Mark Sullivan, the former editor of 'Collier's', who is writing a series on the progress of the campaign". When Mr. Sullivan "wrote an article showing that Hoover hadn't a chance on earth of getting the Republican nomination", the editor of the 'Bulletin' "squeezed the whole thing", that is, declined to publish it. What a bold bad man! How about it? is it proper for a publisher to decline an advertisement with the sentiments of which he does not agree, and is it proper for an editor to reject an article that runs counter to his views? Are the two refusals subject to the same condemnation? Of course, not. The advertising manager of a newspaper is in a category with an innkeeper or a common carrier; he is bound to trade, always provided the purchaser of space is advocating nothing illegal and expresses himself in language that falls short of being obscene or otherwise contrary to law. Mr. De Young could not reject the Hoover propaganda because it was either libellous or indecent, for it was neither, and moreover, his own performances render ridiculous any squeamishness on his part. No, the advertising pages of a periodical publication are for sale, and sold they must be to anybody willing to pay the regular rate. Moreover, it was poor sportsmanship on the part of a newspaper that has been making characteristically the meanest kind of attacks on Mr. Hoover to refuse the retort proffered by his supporters. As to the action of the editor of the 'Bulletin', that is quite another story. The reading pages of a reputable paper are not for sale at any price; the editor is, or should be, the sole judge of the desirability of printing matter that is submitted to him; in arriving at a decision, he should appraise the article by its interest to his readers,

for his first function as an editor is to print what is interesting; to be interesting it must be true, for untruth soon ceases to be interesting to any but perverted minds. Again, an editor, if he have the spirit of sportsmanship, will publish views contrary to his own, particularly criticisms of his own utterances, because these are interesting to his readers—far more interesting indeed than expressions of approval or concurrence. We think the editor of the 'Bulletin' was within his rights in scrapping Mr. Sullivan's article, but he showed lack of courage unworthy of Mr. Hoover's cause. We would have printed it and then written a supplementary article to prove Mr. Sullivan entirely wrong.

Gold Production of the World

Statistics of production from the principal gold-mining regions of the world are now available. The British dominions report as follows:

	1919		1918	
	Oz.	£	Oz.	£
South Africa.	8,330,091	35,383,974	8,418,292	35,758,636
Rhodesia . . .	585,700	2,439,498	624,000	2,652,250
West Africa.	292,500	1,240,691	307,950	1,333,553
India	461,171	1,959,976	485,236	2,062,253
Australia . . .	1,074,713	4,565,088	1,277,474	5,426,360
Canada	767,167	3,260,459	699,681	2,973,644
Other regions*	175,000	750,000	200,000	800,000

*Est.

11,686,342 49,659,686 12,012,633 51,006,696

We give the output in ounces and in pounds sterling, as published, because the variation in exchange and the fluctuation in the premium on gold render it impracticable to give the totals in dollars; however, if the total of fine ounces be multiplied by \$20.67, the grand total of production is \$241,556,689 in 1919, as compared with \$248,301,124 in 1918. The decrease is only 2.3% because the premium on gold stimulated mining in the premier district, the Witwatersrand, in South Africa, during the last quarter of 1919. In that year the United States produced 2,829,395 ounces, worth \$58,488,800, as against 3,313,373 ounces, worth \$68,493,500 in 1918. Semi-official statistics for Mexico indicate a decided increase of output in Mexico during 1918, namely, \$19,600,000, followed by a decrease to \$17,750,000 in 1919, as against \$7,690,000 in 1916. Further statistics are not available. In 1918 the "other" countries, including Mexico, contributed \$56,700,000 out of a world total of \$372,518,400, the decrease from the preceding year being equivalent to 17%. If the decrease was 12% last year, then their output was \$50,000,000. Thus the estimate for 1919 is:

	1919	1918
British dominions	\$241,556,689	\$248,301,124
United States	58,488,800	68,493,500
Other countries*	50,000,000	56,700,000

*Est.

Total \$350,044,489 \$373,494,624

It would appear therefore that the world's output of gold last year was about 350 million dollars, as against the record of 469 million dollars in 1915. This represents

a decrease of 25% in four years. It will be noted that last year 70% of the total was produced under the British flag; it is likely that the proportion will increase during the current year owing to the stimulating effect of the premium paid on gold in London. American production is likely to decrease to \$50,000,000 on account of the adverse conditions obtaining in this country, unless the proposed bounty of \$10 per ounce on new gold is granted by Congress.

Director U. S. Bureau of Mines

Resignation of Mr. Van H. Manning as Director of the U. S. Bureau of Mines is announced, and it is stated that he is to become director of research for a newly organized American Petroleum Institute, composed of the leading oil producers of this country. The news of his resignation was anticipated, but is none the less unwelcome, because Mr. Manning has proved himself a conscientious and capable public servant. During his directorship the Bureau of Mines has gained greatly in importance, partly by reason of the rôle it played in war economies, partly on account of the general expansion of its normal activities. Mr. Manning has proved himself a worthy successor to his friend and former chief, the late J. A. Holmes, the first director of the Bureau. The selection of Mr. Manning's successor will be engaging the serious attention of the Secretary of the Interior and of the mining public, for the position is one of steadily growing responsibility and importance. The first name to suggest itself, of course, is that of Mr. H. Foster Bain, who acted as assistant to Mr. Manning during the War. He is now in the Malay States engaged in the examination of mines for private clients. His familiarity with the work of the Bureau of Mines, his high character and wide popularity, alike recommend him for consideration to the appointment. He has the engaging personality and mental qualities fitting him admirably to serve as a Federal official. It is possible, however, that the reasons prompting him to resign as assistant to the Director may militate against his acceptance of the major office. Among others whose names suggest themselves are Mr. Edward W. Parker, now director of the Anthracite Bureau of Information and formerly with the U. S. Geological Survey. Mr. Parker has proved his ability in several capacities. He also has the personal qualities desirable for an important public office and a wide acquaintance with the various phases of the mining industry. Another able man likely to be mentioned is Mr. Courtenay DeKalb, who did yeoman service for the producers of the secondary war minerals and proved his ability as a spokesman for the Western miner. As a writer and a scientist, of course, he holds a premier position. We venture to mention a fourth name, that of Mr. George D. Louderback, Professor of Geology in the University of California. He is honorably known not only locally but in Washington for his excellent work in connection with war minerals. He exhibited good sense, mental keenness, and skilful initiative during the trying times when it was necessary to stimulate and co-ordinate the production of the minerals most needed to

supplement the shortage caused by the lack of shipping and the exigencies of international conflict. We shall be glad to receive expressions of opinion on the subject, not for publication, but to guide us in co-operating with the leaders of the mining industry in recommending the best possible candidate for this important position.

War Minerals Relief

In our last issue we published the text of the measure introduced in the lower house of Congress by Mr. M. M. Garland of Pennsylvania. This bill (H. R. 13091) formulates the request of claimants under the War Minerals Relief Act for the right of appeal from the Relief Commission to the Court of Claims. The need for such supplementary legislation has been rendered evident by the fact that previous appeals made to the Secretary of the Interior were referred by him back to the Commission, establishing a vicious circle the absurdity of which was on a par with its unfairness. The measure has been introduced as a bill (S. 4259) in the Senate by Senator Poindexter, who is chairman of the Senate Committee of Mines, to which it has now been referred. It is a great pity that this remedial legislation, meant to correct a real grievance, should have been snarled so effectually in a tangle of conflicting purposes. The members of the Commission, headed by a mining engineer of the highest character and of unquestioned public spirit, have evidently been so anxious to prevent depredation upon the public funds and so eager to detect false claims for relief that they have exhibited undue suspicion of honest appeals and excessive inquisition into honorable enterprises instigated by officials of the Government during the critical period of the War. We have read the larger part of the volume containing the record of the hearings before the Mines and Mining Committee of the House of Representatives. Claimants, previously urged by Government officials to produce the necessary war minerals, were treated as if they were culprits under the law. The Mines Committee came to the conclusion that the Commission erred in its interpretation of the legislative intent and application of the provisions of the War Minerals Relief Act. In one case, that of the Chestate Pyrites Company, identified with the Pratt brothers, in Georgia, it was shown that in ascertaining the ratio of concentration, which was under dispute, the representatives of the Commission calculated the ore that went into the mill in tons of 2000 pounds and reckoned the concentrated product in tons of 2240 pounds, thereby reducing the Pratt claim by \$58,000. As yet not \$1,000,000 has been paid out of the sum of \$8,500,000 appropriated for the purpose of relief, although the Act was passed on March 3, 1919. We are in agreement with the American Mining Congress, whose officers have stood loyally by the side of the miner in his proper effort to obtain the compensation voted by Congress, that a grave injustice is being done by the delay and inquisition to which valid claims have been subjected, and we hope therefore that the Garland bill will be passed without unnecessary delay.

DISCUSSION

Registration of Engineers

The Editor:

Sir—In your issue of February 11 I was glad to see a full account of the proposed law for the registration of engineers, architects, and land surveyors.

Already ten or more States have passed laws in which all of the above-mentioned branches of engineering are compelled to register and others are contemplating similar laws. It is only a case of a short time when practically all the States will have similar laws, and for this one reason, it is time that the engineers got together and drew up a law governing this feature. Under this proposed law, the standard of qualification is high, but they are such that any competent engineer can furnish. As I understand the purpose of this law, it is to eliminate as far as possible, incompetent men from masquerading under the guise of an engineer, and this is why the requirements are set so high.

There is but one criticism that I would like to make, and that is with Section 13, part 2, where it reads as follows: "Practice as a professional engineer, architect, or land surveyor in this State by any person not a resident in this State, when this practice does not aggregate more than fifteen days in any calendar year; provided, that said person is legally qualified for such professional service in his own State or Country." This part of the law practically excludes an engineer from making extensive examinations in any State other than the one in which he is registered without registering in this other State. As you know, this will compel all our engineers to register in many States other than the one in which they reside.

It appears to me that a law of this kind should be drawn up in such a way that it will allow engineers, architects, or land surveyors who are legally registered in any State, to practise their profession unlimited in any other State. Also, an effort should be made to the end that engineers, architects, or land surveyors who are registered under the laws of Canada be allowed to work in this country for a period of at least a month and a like courtesy should be extended by the Canadian engineers to men registered in this country.

As the law now reads, no engineer can practise his profession longer than 15 days in any State but the one in which he is registered. Should an engineer from California be called to examine a property in Colorado, or an architect or land surveyor be called to perform any duty under his calling, if this work took 15 days, which it undoubtedly would, he is excluded from further prac-

tice in Colorado unless he register in that State.

It is my opinion that this law should be changed so that any engineer, architect, or land surveyor who is regularly qualified and registered in his home State, be allowed to practise without limit in any other State or Territory, so long as he keeps up his registration at home.

ARTHUR W. STEVENS.

Atlanta, Idaho, March 27.

The Contract System in Mines

The Editor:

Sir—Regarding contract system of ore extraction, and general underground work, we have a fair example in the Golconda mine, at Kingman, Arizona.

In 1910, after a miners' strike organized by the Western Federation of Miners, the Union Basin Mining Company, John Boyle, manager, established the contract system for all underground work, which continued in force for about four years, and proved satisfactory to all concerned. The mine at that time was down to the 400-ft. level, the contracts, including all stoping and drifting, continued to the 600-ft. level. The ore-shoot was 1200 ft. long and from 6 in. to 4 ft. wide, the levels being 100 ft. apart, all work of drifting and stoping being done by single-hand drilling, and the ore mined was zinc-blende carrying gold.

Three classes of ore were produced, namely, first class, containing 50% zinc, was sorted carefully in the stopes by the contractors and sent out direct to the railroad for shipment to the smelter; second class, carrying 30 to 35% zinc, remainder silica, shale, and diabase rock, was sent to the mill at the collar of the shaft to be crushed and concentrated on jigs and tables; third class, assaying 15 to 30% zinc, also sent to the mill. The company operated the hoist, and furnished the tool-dressers or blacksmiths and all surface-workers. The contractors were given a block of ground, usually 50 by 100 ft., also a set of tools, such as picks. Drill-steel was weighed and each drill stamped with the contractor's number to prevent the mixing up in the blacksmith-shop or in transit. The tools were charged to the contractor by weight and number, so when he got ready to quit he was given credit for the return, or charged with any loss. All ammunition, such as powder, caps, fuse, and candles, was furnished by the company and charged to the contractor at cost. All timber and tram-rails, air-pipes, etc., were furnished by the company, which also attended to drainage of the mine.

The following scale for contract work was adopted.

Stopping and delivering first-class ore at the skip, \$4 per ton; second-class, \$2 per ton; and third-class, \$1 per ton. All ore was weighed at the top landing; the contractor's number accompanied the skip-load and was removed by the top man, who duly credited the contractor with the weight. A grab-sample was taken out of each load and put into a sack marked with the contractor's number for assay. The top-landing man had to be an experienced sampler and a good judge of ore, as for instance, some first-class ore was not clean enough to be sent to the railroad bin, so it had to be dumped into the mill-bins.

All drift-work was paid \$4 per foot, besides the price of the ore recovered as above stated. For each stull put in, \$1.50 was allowed; for half-sets \$2.50, for full tunnel sets \$5. There was no pay for handling waste when filling stopes. The contractor could hire his own help or go in partnership, as he liked. Wages were \$4 per day of 8 hours, and settlement and pay-day was once a month. At that time, 1911, there were 150 men employed in the mine, and the system worked so well that the company was able to pay a small dividend under a depressed ore-market, zinc being quoted at 5 cents per pound. Another advantage was the fact that shift-bosses were unnecessary. The men were satisfied, particularly the Mexican miners. The slogan at that time was 'No metal, no free holes'. Of course, the \$4 per foot paid in driving prospect-drifts kept the miner going until ore was found beyond the pinched part of the vein. He always had his board and lodging if he failed to open up the ore. The production of this mine under the contract system was 1500 tons per month of concentrate and first-class shipping ore, which netted at the railroad station \$25 after all expenses were deducted, including freight to an Oklahoma smelter.

E. HEDBURG.

Kingman, Arizona, April 17.

Precious Metals in Oil-Shale

The Editor:

Sir—Your subtle denouncement, in a recent editorial, of Mr. Elihu Palmer and his absurd deductions of precious-metal wealth in oil-bearing shale beds heartily meets the approbation of shale technologists and chemists who have had occasion to investigate or experiment along this line.

In the past few years I have made a score of investigations of so-called secret or special processes in which the inventor claimed a divine revelation purporting to extract the metals in a tenfold degree, where they exist, or making worthless rock the dream of Croesus. One would have to go deep into psychology for enlightenment as to the real motives of these individuals. Roguery seems the word. Nevertheless from personal contact with them I would likewise attribute such demeanor as the result of quasi-technical knowledge, perhaps from a half-year in college or from a complete newspaper or correspondence course. Such preparation, coupled with a wild imagination, constitutes their qualifications.

In an impersonal way, for the sake of comparison with

Mr. Palmer's assertions, I give you the result of an oil-shale represented as carrying over \$20 to the ton in gold. Said metal contents could only be extracted by a special process, and were detected only by their special method. This work was conducted with all eyes open in a neutral laboratory, and, *mirabile dictu*; the investigation was actually made prior to any investment. The findings were as follows: the sample of shale was crushed and quartered to a few pounds of $\frac{1}{4}$ -inch material. This was mixed, and a charge of 300 grammes was placed in the retort. This was treated in the hearth of a small stove with gradually rising temperature for one hour, at which time all kerosen was fairly well removed. The charge was then drawn, cooled, and ground to 60-mesh. It was then decarbonized by heating in an open muffle with intermittent stirring. The product at this stage was a light buff in color, somewhat agglomerated. It was again passed through the screen, being ready for assay. It now showed 52% of the original weight. At this stage the metamorphosis has taken place. The gold is freed; only an aesthete could possibly know this.

Following came the determination of the gold by two separate methods, one the ordinary crucible assay, and the other by Winner's method, a concoction of several well-known commercial processes now in vogue, with nothing to commend except the patience of the operator. And now the results: the ordinary method showed a value of 25c. per ton in the ash; Winner's method, 28c. per ton. These results reduced to the original shale represent 13c. per ton, by the ordinary method, while Winner's method gives 14 $\frac{1}{2}$ c. per ton. The above results are averages. Individual determinations by each method show an occasional higher result with a vast majority of the determinations nil. From a value of \$10 per ton to that of 13 $\frac{1}{2}$ c., I submit to you for computation the potential "in the hole" on whatever billions of tons you may choose.

You will understand, I am not deerying the shale beds of our State as a great potential resource, nor do I discourage the need of scientific experimental work for sound inductive reasoning and progress in the chemical and metallurgical arts, but such vagaries as you describe should be accompanied by the music of the spheres, and are not for this fair earth. Your timely article should reap the gratitude of the savants, not to mention the chagrin of the nuregenerates.

WALTER E. BURLINGAME.

Denver, April 22.

TWO SMELTERS in New Jersey, two in New York, and one in California, which treat only zinc drosses and skimmings, use large graphite retorts of 600 to 800 lb. capacity instead of the small clay retorts used by smelters treating ore or mixed ore and drosses. The many uses of zinc drosses and skimmings create active competition for their purchase. Considerable zinc is recovered by sweating, and the residues are sold for re-distillation. Secondary zinc varies in quality just as the zinc derived from ore does, but a part of the secondary zinc is reported to be of excellent quality.

The Romance of Mining Discovery

By T. A. RICKARD

*The finding of ore has ever been fortuitous, from that dim dawn long ago when Javan, the son of Japhet, stubbed his toe against a copper outcrop in Cyprus to the evening of a much later day when Juan Bautista, a Mexican herdsman, in Sinaloa, lost his rosary only to find the riches of El Tajo. The story is typical; Juan was chasing a stray sheep when his rosary, becoming entangled in a bush, was torn from his neck. Not stopping to recover it, he threw his hat to mark the spot; later, returning from the chase, in the twilight, he found his hat. It was too late to find the precious beads, so he camped for the night. After making a fire, he went to sleep. Awakening before dawn, he seized an ember to light a cigarette of cornhusk. As he did so, the light fell on something that sparkled; he picked it up and took it to his *patron*, who recognized it as silver. The fire had roasted the ore and released the metal. Nothing is said about the fate of the rosary, but the mining district that thus came into being is known now as El Rosario. It has produced millions.

Lucretius ascribes the first discovery of metals to the burning of forests, and attributes the formation of masses of metal underground to the running together of molten streams into the fractures of the earth. Diodorus Siculus records the finding of silver on the Iberian peninsula, now known as Spain; he relates how shepherds set fire to a forest in the Pyrenees and how the heat sufficed to melt the silver out of the rock. This Greek historian asserts that "the metal flowed in streams of pure silver". The natives did not know what it was and sold it to the Phoenicians, who knew most things that were known at that time. The action of these shepherds in employing incendiarism to clear the forest and make room for the grass to grow for their flocks reminds one of the practice of our Western prospector, who, until the Forest Service stood on guard to check him, would start a forest-fire in order to clear the underbrush and so expose the rocky surface to inspection.

The stories of discovery in the olden time all have a major element of the accidental. The silver of the Rammelsberg in the Harz was found by a noble hunter who had fastened his horse to a tree. The horse, as is the manner of that impatient animal, stamped and scraped the ground with his hoofs so as to lay bare the silver-lead mineral underneath the turf. The horse was named Rammelus; hence Rammelsberg. The hunter selected specimens of the silver ore and sent them to the Emperor Otho. Whether the Emperor admitted the hunter to a share in the subsequent mine, we are not told.

*An address delivered before the International Mining Convention, at Seattle, on April 7, 1920.

In 1170 a Bohemian passed through the forest that then covered the Freiberg district and sat down to rest. At his feet he noticed a stone that reminded him of the ore he had seen in the Harz. He put a piece in his pocket and had it tested. It proved to be galena, rich in silver. Thereupon he informed his comrades and they returned with him to exploit the lode from which the stone had been shed. A better version is given by Agricola, who says that the drivers of the carts that carried salt to Bohemia from the springs in Saxony noticed the galena exposed in their wheel-tracks after a rainstorm. This ore was like that of the Goslar district, where they lived, so they took some of it to be assayed. It proved richer in silver than the Goslar ore, whereupon they betook themselves to that part of Saxony where Freiberg now is and started mines of their own.

Here we have the beginning of inductive reasoning, which is the foundation of science. Huxley said that science was only organized common sense, and that is what those Bohemian teamsters displayed by their inference and by their action.

Next we turn to South America, where we shall see how the ignorant native by chance found some of the great ore deposits of the world. In 1545 an Indian was hunting deer on the slopes of the Cerro de Potosí, in Bolivia, when he took hold of a shrub to pull himself up a steep place. His weight uprooted the shrub and exposed a mass of native silver in the rock. About the year 1630 another Indian, a shepherd on the Cerro de Paseo, lit a fire on the mountain-side and found later that he had melted silver out of the rock underneath the ashes. That was the outcrop of a vein famous in Peruvian history, but now associated with an important copper-mining enterprise. The Cerro de Paseo furnished the Spaniards with a million ounces of silver per annum for three centuries; the yield of Potosí is estimated at more than four billion ounces of silver.

The two greatest mines in Australia had strange beginnings. The story of the Mount Morgan mine, in Queensland, is a melodrama. This golden quarry is on the original 'selection' of 640 acres taken up by Donald Gordon for grazing purposes in 1873. His brother Sandy, a shiftless fellow, was grubstaked by Burns & Twigg, who had a foundry at Rockhampton, 26 miles from Mount Morgan. Sandy Gordon told them about a big red lode on his brother's land, but he was a cheerful liar and they paid no attention to his tale. They sent him to the Morgan brothers, Ned and Tom, who employed him, and, being prospectors themselves, thought enough of his tale about the big lode to go and see it in July 1882. First they went to examine what Sandy called a silver lode and

then they did some prospecting on Donald's ground. They noticed some ironstone boulders in a stream at the foot of a rocky hill rising out of the tropical bush; the stream was Mundie creek, which flows round the base of Mount Morgan. They chipped a piece of the reddish rock, which they crushed and panned on a shovel. It was full of fine gold. They said nothing to Sandy about it, but returned home and proceeded to organize a syndicate, which included Thomas Hall, William K. D'Arcy, and William Pattison, all of whom became millionaires. To Burns & Twigg, from whom they had borrowed the services of Sandy, the Morgan brothers offered a share in the discovery for a 10-stamp battery. The offer was declined. Sandy Gordon died as he had lived. It is said that the Morgans paid him £20 and as much whisky as he could drink. Donald sold his land to them for £1 per acre, not knowing what was on it. He died of chagrin. The mine is still richly productive, yielding copper in the deeper workings, as well as gold. Up to the end of 1919 it had produced \$92,000,000 in gold and \$34,000,000 in copper, making a total of \$126,000,000, from which \$58,000,000 has been distributed in dividends. The pathetic story of Donald Gordon has been embalmed in verse by Brunton Stevens, an Australian. The poem is called 'The Lost Chance'. I give you one verse of it:

"Just to miss it by a hair-breadth—nay, not to miss it!
to have held it
In my hand, and ofttime through my fingers run the
swarthy ore,
Minus only the poor trick of art or science that com-
pelled it
To unveil for others' good the hidden value, and to
pour
On a thousand hearts the light of hope that shines
for me no more."

Broken Hill was discovered at about the same time. A rough black ridge, like a reef, rising above the level of the dusty plain, this great outcrop was ignored for many years by the 'boundary-riders', or cowboys, on the adjacent Mount Gipps 'station', or sheep-range, in New South Wales. When they began to surmise that the dark rock might mark the line of an orebody they guessed that it must be a tin lode. Samples were broken and assayed for tin, without result. However, they pegged a number of claims on the off-chance, for lumps of silver chloride—hornsilver—had been found on the surface not far from this Broken Hill, as they called the black ridge. That was in 1883. A syndicate of seven station-hands was organized, each contributing £70 to the fund for sinking a shaft in search of silver ore. Of course, this shaft was started at the leanest spot on the outcrop; only a low-grade lead-carbonate was struck. The original working capital was soon spent. Two members of the syndicate retired and the number was increased to 14 in order to raise more money. Sinking of the shaft was then resumed, and, toward the close of 1884, some rich chloride ore was cut at about 100 ft. in depth. The shares had gone to a discount. The story is told that McCulloch, the manager of the station, played *enchre* with Cox, one of his partners in the prospect, to determine whether he

should sell one of his three shares for £100 or for £150. McCulloch won, and sold for £150 a share that six years afterward was worth £1,250,000. An engineer told me, when I was in Melbourne in 1889, how he went to Broken Hill, at the time when the first shaft was being sunk, to advise a client as to whether he should buy a share in the syndicate. On arrival at the prospect he found the superintendent absent and the men would not allow him to go underground. He took some samples of the rock on the dump and had them assayed at Adelaide, with an unsatisfactory result—only 16 ounces of silver per ton. The rich ore had been struck the very day of his visit, and if he had been more adroit he might have elicited the information from the miners.

In both these Australian stories we see the rudiments of scientific investigation. The science is thin indeed, but the use of the pan or the crucible to determine the presence of gold or silver marks the beginning of methods that are now established. The blindfolded goddess Fortune has had her bandage loosened so that she can glimpse the way she is going. Mining becomes less of a lucky grab into a half-opened sack and more nearly a systematic study of the signs that indicate mineral riches. "Science moves but slowly, slowly, creeping on from point to point."

In later days it has become fashionable to impute to science an exaggerated share of the credit for the discovery of mines. I recall two examples in Colorado: the Independence and the Camp Bird. The discovery of the Independence vein by W. S. Stratton resulted from the desultory prospecting of a carpenter. He had had a little experience in the Silverton district and was living at Colorado Springs when Cripple Creek came into prominence early in 1891. After trying several places in the district, he found a little gold in the broken rock covering the southern slope of Battle mountain, but his pannings led to nothing, because he did not know enough to test the outcrop of mineralized granite that was the one conspicuous feature of the hillside. Finally, at a loss what to do and noting the fact that the proportion of gold in the surficial debris diminished at about this point, he broke a piece of the granite and took it with him to Colorado Springs for assay. It assayed 19 ounces of gold per ton! That was on July 3, 1891. He returned next day and located two claims, the 'Fourth of July' and the 'Independence'. The Independence was the only vein in the Cripple Creek district that had an outcrop and it was one to which any intelligent prospector would have been attracted at once. The feldspar and mica had been decomposed and in their place were iron oxide, sericite, and gold. Stratton's only experience had been with the white quartz veins around Silverton; so he spurned what he called the "rotten granite", simply because he knew no better. When the Independence became famous his friends fabricated a yarn in which his knowledge of chemistry and mineralogy supplemented his energy as a carpenter so effectively as to give him the pose of a scientific explorer. One correct inference, however, must be allowed: when the float, or 'shode', as a

Cornishman would say, panned poorly, he recognized that he had passed the source of the gold; he looked up, as it were, and saw the granitic outcrop, surmised its possible agency in enriching the breccia on the hillside, and broke a sample. Let us give him credit for that. The Independence yielded \$22,000,000, of which \$10,000,000 was profit, divided between owners, tributaries, promoters, and ore-thieves.

The Camp Bird mine is in Imogen basin, near Ouray, a lovely summer resort in south-western Colorado. The discoverer, Thomas F. Walsh, also had been a carpenter when he obtained his first experience of mining at Leadville. Later he had done well at Cripple Creek. In 1896 he was running a little smelter at Silverton and needed quartz to mix with the pyritic copper ores of Red Mountain. He was looking for silicious ore. For several months he had been opening up a silver-lead mine, called the Hidden Treasure, in Imogen basin, and on one of his periodic visits, in July 1896, he happened to notice some pink spar in the dump at the mouth of an abandoned tunnel. He thought this pink spar was fluorite, with which he had become familiar at Cripple Creek, where he leased the Summit and Deerhorn mines from Stratton. Walsh told Andy Richardson, a prospector in his employ, to take a look at the old tunnel from which the pink spar had come, but nothing appears to have happened. In September he examined these old workings himself and took some samples, which he sent to Ouray to be assayed. They showed several ounces of gold per ton. More samples were taken and sent to Leadville for assay, with confirmatory results. Walsh kept this information to himself and set to work to secure title to the Gertrude claim, on which was the tunnel, as well as the adjacent ground, most of which he acquired by paying delinquent taxes. He located a claim next to the Gertrude and called it the 'Camp Bird'. Within four years he owned 103 mining claims and 12 mill-sites, covering 941 acres in all. By that time he had taken \$2,500,000 gross out of the mine and made a profit of \$1,650,000. He sold the mine in 1901 for \$6,500,000. During its life the Camp Bird yielded \$23,000,000, of which \$11,500,000 was profit.

On May 22, 1908, Tom Walsh gave an address before the Colorado School of Mines and recounted the story of his discovery in order to emphasize the value of technical science, especially mineralogy, to the miner. He told the students how he noticed a slide of "red pyritiferous porphyry" because it had "a very strong indication of gold in or near it". Samples of this rock assayed \$2 in gold. This "confirmed his suspicion" that there were gold veins in the vicinity. Among the claims acquired by him in the hope of obtaining silicious ore for his smelter at Silverton was one near the "porphyry slide"; he suspected that the vein on which this claim was located must pass, as he said, "through or near the porphyry dike and that it carried gold". So he went to get some samples and found "a dump of very showy ore, having zinc, lead, and some copper pyrites". He concluded his story thus: "I went inside and examined the vein. There I found an 18-inch streak of the same kind of ore

that was on the dump. Between it and the hanging wall there was about three feet of modest-looking quartz. As I examined it closely I saw little specks and thread-like circles of glistening black mineral all through it, which experience told me was gold in a telluride form". Samples of this quartz assayed "as high as \$3000 per ton".

This version of the discovery interested me greatly when I read it in print, because it was not the story that he had told me himself, in the presence of Andy Richardson, as we stood within sight of the old Gertrude tunnel in July 1900. I had taken down the real story in my notebook and therefore did not have to trust that most dangerous recorder, the memory. You have listened to the original version already and can make your own comparisons. The pink spar that aroused his interest was not fluorite, but rhodonite, the silicate of manganese. Thus his incentive toward inspection of the vein was founded upon an error; the analogy with Cripple Creek was false, but it served its purpose, which was to prompt the taking of a sample. The telluride of gold, calaverite, is not black, it is a bronze-yellow mineral, like chalcopyrite, but easily distinguishable from copper pyrite by its hardness, streak, and more brilliant lustre. The description of the black threads of glistening mineral is based upon information of a much later date, when it was ascertained, thanks to microscopic examination by C. W. Purington and others, that the black filaments in the Camp Bird ore consisted of free gold, galena, blende, and occasional traces of a telluride, the identity of which was never determined with certainty; in any event, it was not recognizable by the naked eye and bore no likeness either to the calaverite or the sylvanite found at Cripple Creek. Walsh deserves credit for taking samples and having them assayed. That was a test more trustworthy than any surmise based upon a half-baked mineralogy. What is more, he owed his luck to the failure of a predecessor to use the assay-test thoroughly. The romance of the Camp Bird belongs to Walsh, the pathos to William Weston. The Gertrude claim was located by Mr. Weston and George Barber in 1877 and formed part of the property acquired by the Allied Mines company in 1878. The workings found by Walsh in 1896 were made by H. W. Reed and Caleb Reed in 1884. Mr. Weston was manager for the Allied Mines, a wild-cat enterprise upon which Rossiter W. Raymond reported adversely in 1878. Andy Richardson told me that on the window-ledge of the log cabin that served as an assay-office for the Allied Mines company he found a piece of ore identical with the rich samples that Walsh had broken in the Gertrude tunnel and that gave him a key to the fortune of a millionaire. It is evident that his predecessors had failed to assay the ore for gold. Silver mining was then in vogue in Colorado. The ore was tried for silver alone and the assayer had failed to part the button. Others, possibly Mr. Weston, possibly Mr. Reed, had held the ore in their hands and had even ascertained that it was relatively poor in silver. For lack of a complete assay they had missed the chance of a lifetime. Perhaps they are luckier for it, who can tell? Walsh crossed the range many years ago; they live and

are honored citizens, the one at Denver* and the other at Salt Lake City.

Two carpenters who build better than they knew, not ordinary houses, but castles in Spain, have been mentioned. They dreamt they dwelt in marble halls and found themselves less comfortable than in the log cabins of their prospecting days. Another adventurous carpenter was John Treadwell, who gave his name to the Alaska Treadwell mine, which produced \$39,498,215 in gold and paid \$15,785,000 in dividends before (on April 21, 1917) the waters of the sea drowned the workings and stopped further digging. The locator was Pierre Erussard, a French Canadian, known to his friends as 'French Pete'. He lived with the Indians, as many prospectors have done. When the news came to Sitka, then the capital of Alaska, that gold had been found near Juneau, Pierre started forth in a canoe, accompanied by several Indians, one of whom was his wife's brother. They landed on the beach of Douglas island in November 1880 and found gold in the sand. Pierre looked for the source of this gold and discovered an outcrop of quartz that panned fairly well; it was on the hillside about a quarter of a mile from the shore. He located two claims; one of them he called the 'Paris', after the capital of France, which in turn was named after an ancient disturber of the peace; the other he named the 'Bear's Nest', because he found the ground occupied by a bear and her two cubs. The frosts and the thaws of a wet climate had disintegrated the outcrop so that Pierre could shovel the broken quartz into his sluice-box. Later he drove a shallow tunnel into the hill so as to cut the lode a few feet below the moss-covered surface. That was the beginning of the Treadwell mine. Pierre did pretty well by washing the softer and surficial portion of the lode in his rocker and sluice-box, but it was no bonanza, compared with the riches gathered on the mainland, two miles distant on the other side of Gastineau Channel. The diggers on Gold creek were making money faster, so Pierre sold one of his claims a year after his discovery. The record says: "September 13, 1881. Transfer of Paris lode from Pierre Joseph Erussard (or 'French Pete'), original locator, to John Treadwell, in consideration of the sum of five dollars (\$5.00)."

The purchaser, John Treadwell, was a builder and contractor with some experience in mining, for as early as 1869 he had worked in White Pine county, Nevada, and for 12 years before going to Alaska he had been engaged both in quartz and hydraulic mining in Nevada and California. At the time when Pierre was at work on the shore of Douglas island, Treadwell was building a house for John D. Fry, a banker in San Francisco. To Colonel Fry and his friend James Freeborn there came the story of a rich prospect in the range behind Juneau. Looking around them for a man whom they could send to investigate, they selected Treadwell as being both trustworthy and sufficiently experienced in mining.

*I regret to record the fact that Mr. Weston died on March 30, after the above was written. See 'M. & S. P.', April 24, 1920.

Moreover, he had been hurt in an elevator accident and needed a change of air. They agreed to pay Treadwell's expenses and to give him a fifth interest in the mine, if the purchase was recommended. Treadwell went north, examined the prospect, and found that it was only a stringer of quartz carrying a little free gold—just the sort of show to beguile a 'tenderfoot'. Treadwell saw that most of the rich ore had been dug out. Disappointed, he decided to return to San Francisco, but to do that he had to wait for a steamer. While waiting at Juneau he met Pierre, who had opened a small store in this pioneer settlement and happened to need a little ready money to pay for freight on goods that had just arrived from the south. He wanted \$300, for which he was willing to trade an interest in his claim on Douglas island. Without going to see the claim, Treadwell 'took a flyer', and advanced \$300 out of the funds intended for the purchase of the other prospect. Then he went across the strait to see what Pierre had in the way of a mine. Treadwell liked the look of the lode and took a bond on the Paris claim for \$20,000. Still awaiting a steamer to take him home, he spent his time in testing the prospect by panning. He remained two weeks at Pierre's cabin. Just before leaving, he told his host that the ore was too poor, and suggested that if Pierre would give him a quit-claim deed for \$5 he would try to sell the mine in San Francisco, with a promise to trade at Pierre's store if a sale were consummated. The deal was made. Treadwell departed, returning on May 17, 1882, with a five-stamp mill, which he erected on the Paris claim. His backers, Fry and Freeborn, carried out their agreement and organized the Alaska Mill & Mining Co., in which Treadwell obtained a fifth interest. Within five years the mill was enlarged to 120 stamps and in 1899 there were 540 stamps at work, the production in that year being 250,408 tons, yielding \$677,655 in gold. In 1890 the property was transferred to the Alaska Treadwell Gold Mining Company. Up to that time the mine had produced 617,112 tons yielding \$2,339,398, or \$3.79 per ton. The purchase price was \$16 per share for 100,000 shares, so that Treadwell's interest brought him \$320,000, besides his part of the dividends that had been paid during the preceding eight years, namely, \$650,000. So the Paris claim brought him \$450,000 in all. He made a small fortune (\$600,000) by the sale of a quick-silver mine to D. O. Mills, who acquired a large interest in the Alaska Treadwell also; in short, John Treadwell became a veritable millionaire. He lost most of his capital in the Tesla coal venture near Stockton, California, in 1906; but he did not go under; on the contrary, he is still active in mining and financial affairs in New York, although he is now 80 years old.

Among the romantic mineral discoveries of recent years I like to instance the United Verde Extension, known as the 'E. V. X', at Jerome, in Arizona. The story of this remarkable find of copper is pleasant to tell because it illustrates the more scientific methods of a later day. It is true, a large element of guess and of accident still survives even in the least fortuitous pros-

pecting, but it is satisfactory to see how reasoning from ascertained facts will guide an intelligent man to the uncovering of treasure underground; in short, mining becomes mining engineering.

The old United Verde mine at Jerome has produced 5000 tons of refined copper and has made a fortune for W. A. Clark, formerly senator from Montana. This mine is on the side of a mountain, the flank of which is traversed by a big fault that throws the ore-bearing formation vertically downward about 1700 ft. and horizontally about 900 ft. To the miner this is a serious dislocation, because it has placed the lower portion of the favorable formation beyond his observation except by shaft-sinking; he has no outcrop or other surficial signs of ore to guide him in prospecting. The ore in the United Verde is found in schist where it is penetrated by tongues of diorite. The schist below the fault has been covered by later sediments, now consolidated into beds of sandstone and limestone, these sedimentary rocks being covered in turn by a flow of basalt. Although the existence of the fault was detected in the early days of the district and it was deduced by those who understood geology that the continuation of the ore-bearing schist and diorite was to be found somewhere deep down in the earth, if only it could be reached, nevertheless to do that involved a good deal of expense; the depth to be penetrated was not known accurately; and when the favorable formation was reached it would still be necessary to look for an orebody as if it were a packet of needles in a haystack. It was a long shot and a hazardous venture. Nothing was done for a long time. The United Verde paid its first dividend in 1892; the search for its brother deposit of copper was not started until 1900. In that year a surveyor named J. J. Fisher commenced the sinking of a shaft on the 'Little Daisy', a fractional claim just below the line of the fault. Fisher died before his hopes were fulfilled. Louis E. Whicher continued the exploration and acquired sufficient ground to justify an expensive enterprise. The shaft was sunk through the basalt and the underlying sedimentary rocks into the schist; at 800 ft. patches of copper ore were found, but not enough to make a mine. This was in 1911. Already eleven years had passed and \$500,000 had been spent. Several mining geologists examined the ground and reported adversely. They thought the chances too slim.

At this juncture James S. Douglas was invited to take a hand; he made an inspection of the evidence available and was favorably impressed. In the summer of 1912 Mr. Douglas and George E. Tener took hold of the venture and raised \$250,000 as working capital. In the letter that they sent to their mining friends, inviting them to subscribe, they stated: "Mr. Tener and Mr. Douglas are not asking their friends for subscriptions, but believe that their plan for the development of the United Verde Extension Mining Company's property will result in the discovery of valuable orebodies, and in sending you this letter, it has occurred to them that you might consider it a favor to be permitted to join in a speculation which they recommend as such." What a contrast to the

phraseology of an ordinary prospectus! The friends, most of whom were experienced and successful mining engineers, did consider it a "favor" to be let into the deal and sent their subscriptions cheerfully. Mr. Douglas is the son of James Douglas, who died two years ago, a man whose name is synonymous with honorable and intelligent mining enterprise. The father, who, as you know, was identified with Phelps, Dodge & Co., was one of the subscribers to his son's venture; so was his brother, Walter Douglas, likewise distinguished in mining, especially in Arizona. James S. Douglas, the discoverer of the U. V. X., is a Western man of the best type, big and strong, mentally as well as physically, outspoken and direct, unconventional almost to a fault, but absolutely dependable. In June 1913, as soon as the requisite funds had been collected, he started a new shaft, at a point 1900 ft. east, and farther from the fault, than the Little Daisy shaft. The new shaft was sunk to 1100 ft. and connected with the old one. Cross-cuts were extended in search of ore, but unsuccessfully. Soon all the money of the company was spent. The shareholders were asked to subscribe for additional stock, upon which \$50,000 was realized. Douglas and Tener underwrote the issue. This \$50,000 likewise was spent, and still no ore was found. In the fall of 1914 Douglas and Tener, not caring to call upon their friends again, advanced \$25,000 of their own money to continue the work. They engaged a distinguished geologist to tell them where they had erred in their exploration. This gentleman advised them to cease operations; and it looked very much as if the advice ought to be taken. However, as the Cornishman says, "Never abandon a drift until you have driven twenty feet farther." Douglas decided to persevere a little longer, and in December 1914 a cross-cut that was being extended toward the centre of the U. V. X. ground, from the main level at 1200 ft. connecting the two shafts, cut five feet of 45% copper ore. From this orebody about \$600,000 worth of copper was won during 1915. But the best was yet to come. The prospect had become a mine, but it was destined to be a bonanza of the very first class.

A drift was started 200 ft. below, on the 1400-ft. level, to get under the orebody, but it went beyond the point where the ore was expected and found nothing. A heavy flow of water hindered exploration; large pumps had to be provided before the work could proceed. Then a cross-cut was driven each way from the drift on the 1400-ft. level, but both branches drew a blank, because, as was ascertained later, the orebody had taken a decided dip westward. Another cross-cut failed; but the third struck 16% ore at 40 ft. from the drift and continued in ore for 200 ft. more. This was *not* the orebody cut previously on the 1200-ft. level; it was another and a bigger one, which proved to be 260 ft. wide and 440 ft. long. It reached upward to 40 ft. above the 1200-ft. level; between 1250 and 1500 ft. there was estimated (in 1917) to be 2,000,000 tons of 15% ore, representing 600,000,000 pounds of copper. Besides this chalcocite ore, the product of secondary enrichment, there is about 1,500,000 tons of primary 5% pyritic ore from which further profits will

be derived. The bonanza promises to yield 3,500,000 tons of 10% ore. In the following year (1916) the U. V. X. produced 36,402,972 lb. of copper from 77,161 tons of ore, an average of 23.5% copper, besides 2570 oz. of gold and 128,168 oz. of silver, the total output being worth \$9,919,918, of which \$7,100,000 was profit. Douglas struck it alright, alright! It was one of the most remarkably concentrated masses of chalcocite ever uncovered by the pick of the miner. When I saw a earload of it, just off the cage, at the surface, it looked to me like bituminous coal; it blackened the fingers. That earload assayed about 40%. In April 1917 the mine produced 4390 tons of 38% ore and 7029 tons of 26% ore, containing therefore 6,991,480 pounds of copper, worth 2,167,358 dollars.

This is a story of the kind of prospecting that must replace the gophering of an earlier day. To study the sunlit surface will not suffice, because all the obvious outcrops will have been found; it will be necessary to dig down into the darkness underground, steering by the light of scientific induction. That is what Douglas did. He had a good general idea of the local geology and of the structural conditions produced by the fault; he drew inferences from the signs of copper in the Daisy workings, more particularly the finding of a small patch of chalcocite, which indicated secondary enrichment, with the prospect of finding rich ore at a lower horizon. His experience of mining elsewhere in Arizona was helpful to him; it gave him the right feeling, or intuition; and on top of that he had courage, and more courage, as well as the money to back it. He has made a lot of money and it has not spoiled him. In this respect he differs from most of those whom our daily press calls "bonanza kings"—for the common scribe is so hard-up for epithets that he has to go for them to an outworn system. Of course, Mr. Douglas is an educated man, and that is why, among other reasons, the romance of his adventure has not had a sequel of pathetic demoralization, but, instead, patriotic effort during the War and enlightened public service at all times.

No story of mining discovery is complete without a reference to the Bunker Hill & Sullivan mine, in the Coeur d'Alene. Most of you have heard the tale and probably most of you are familiar with the fiction that has long passed current for fact. The version formerly accepted was that an old prospector lost his burro and found him standing upon an outcrop of galena; later, it is said, the men who had grubstaked the prospector claimed a half-interest and were awarded a share in the discovery because their burro had participated in the finding. Jim Wardner, in his book, even went so far as to put a fictitious decision in the mouth of the judge: "From the evidence of the witnesses, this Court is of the opinion that the Bunker Hill mine was discovered by the jackass, Phil O'Rourke, and N. S. Kellogg; and as the jackass is the property of the plaintiffs, Cooper & Peck, they are entitled to a half-interest in the 'Bunker Hill' and a quarter interest in the 'Sullivan' claim." This is fiction. By referring to the record of the case, I find that what Judge

Buck did decide was: "That the plaintiffs are entitled to a decree as against N. S. Kellogg and Phil O'Rourke for an undivided fourth interest of in and to the Bunker Hill mining claim, as described in the complaint as they held the same September 10, 1885, and all interest acquired since said date in and to said claim and judgment for costs against defendants." He said nothing about the burro; that animal served as a herring across the trail of dishonesty, yet for more than thirty years he was the hero of the tale or a hero with a tail. The glittering galena by which, according to Kellogg, he was hypnotized, resembled the "red" lobster described by the man who had eaten specimens of that succulent crustacean, but had never seen one alive. Galena, as you know, oxidizes readily when exposed to the weather; it loses its bright lustre, changing to the sombre sulphate or the dull carbonate, both these products of decomposition becoming reddened or blackened by the iron released from the oxidation of small quantities of pyrite associated with the galena. The outcrops of lead lodes in the Coeur d'Alene consist commonly of dark-red ironstone with gray anglesite (the sulphate of lead) or cerussite (the carbonate), in the midst of which small unoxidized cores of galena may survive. Neither the jackass nor his comrades saw any mass of silver-white galena on the surface of the Bunker Hill claim. The evidence indicates that Noah Kellogg found the outcrop of ironstone and located it. He chipped off a few pieces, including one or two that contained galena. When he showed his samples to O'Rourke, who had mined at Leadville, that wily son of Erin led him straight into temptation, namely, to evade his obligation under the grubstake. Only the ironstone was shown to Cooper and Peck, who had no use for such poor-looking stuff, and said so, thereby giving Kellogg an excuse for terminating his agreement. Thereupon Kellogg and O'Rourke re-located the Bunker Hill and the adjacent claims, but, unfortunately for them, the original and discarded location notice was found by Peck a few days later and gave a clue to their trick. The litigation was not ended when the mine was sold, and, in order to clear the title, the prospectors were paid a considerable sum of money, all of which they lost in a few years. They died paupers. The burro fared best. When superannuated he was placed on a farm in Oregon, where he died full of years and honors, even his burial being made the occasion for the expression of lofty sentiments in accord with the myth that had been concocted to his memory.

This is not a pleasant story; it is overcast with bad faith, as the galena was coated with dross. Yet I venture to say that such breaches of honor are rare among prospectors. If they were common, the custom of the grubstake would be discarded. That is obvious. I like to recall the story of the Florence mine at Goldfield. In 1883 Alexis D. Parker, who was then working as a laborer, for the sake of experience, on the Denver & Rio Grande railroad, grubstaked a miner named Thomas D. Lookhart; he continued to do so for 18 years; even when Parker was earning only a small salary as an accountant,

he managed to save enough money to back Lockhart in his prospecting expeditions, but without any noteworthy result. In 1901 Lockhart went to Tonopah and located two claims near the find that had been made by Jim Butler, who, as everybody knows, was the discoverer of that famous district in Nevada. Lockhart was informed that he had overlapped some ground already located, so he moved off southward and located two other claims. They were on the sage-brush plain; they showed no signs of ore, and their validity as locations might have been questioned. Meanwhile the work done on the Mizpah claim of the Tonopah mine indicated the strike of that vein, so Lockhart began to sink a shaft through the rhyolite that capped the ore-bearing formation. He started the shaft unaided; he would climb down to the bottom and fill the bucket; then, climbing to the surface, he hoisted it with his windlass. This shaft became the main opening of the Tonopah Extension mine and penetrated rich ore at 237 ft. In March 1902 Charles M. Schwab bought the Tonopah Extension for \$75,000 from Lockhart. For several years he had received no financial aid from Parker and he was entirely free from any legal obligation to give him any part of his stake, yet he lived up to the spirit of their comradeship and handed him \$37,500. After this start, Lockhart went to Goldfield, 24 miles from Tonopah, and acquired the Florence mine, paying \$7000 for a half, with an option on the control. George Wingfield and George S. Nixon took a lease on the Florence and the royalties they paid gave Lockhart the money needed to complete his purchase. Soon after he had made this deal, Lockhart overheard one of the owners ehuekling over having got the best of him, but his confidence in the mine was not shaken. He told Parker about it, informing him that he need not come into the deal unless he wanted to do so. Parker replied that he would share equally with him in all his mining ventures. They did well.* The mine paid \$735,000 in dividends. Mr. Parker is now a director of the Colorado & Southern Railway Co. I heard from him last week; in his letter he says: "The pith of the story of the grubstake of Lockhart and me is that each gave of his best to the other. It is a story of absolute honesty. We never had any written agreement, each considering his word as good as a signed paper. What is still better, we kept our word. I did my part in furnishing the grubstake and in standing by Lockhart after we made our money. He never failed to put my name on all locations and to hand over to me an undivided half-interest."

The miner's pick never opened a greater treasure-vault than the Comstock, yet the story of its discovery is more sordid than romantic. In 1859, and for eight years previously, immigrants had strayed from the overland trail into the valley of the Carson and up one of the creeks to Gold Cañon. There they had obtained a scant living by desultory washing of the gold from the detritus in the gullies on the sides of Mt. Davidson, or the Sun Peak, as they called it then. They were an ignorant and

a shiftless lot. The gold that they saved and the 'black iron' that they threw away came from the outcrop of a great vein, but they had no notion of the relationship. The 'black iron', rejected with many an oath because it mixed with the gold in their sluice boxes, consisted of silver sulphide—probably stephanite—but they did not know it. Slowly, inevitably, these placer miners worked their way to the disintegrated parts of the vein itself, where the diggings became very rich. The gold was pale in color, but there was plenty of it. To their surprise, the 'pay dirt' led right down into the earth. They continued to dig and to wash out the gold, unaware that they were on the edge of the greatest ore deposit in the world. A passing stranger—a farmer from Truckee—took a piece of the discarded 'black iron' over the Sierra to Grass Valley, where he had it assayed. The stuff was nearly a quarter silver. Quietly this man and a few friends left that night on horseback for the new mines, then known as the Washoe diggings, where they bought out the discoverers for a song. The news spread; others came; then more and more, until within a few weeks hundreds were rushing across the mountains from California to Nevada. That was in June 1859.

The Comstock Lode, as the great vein was called, was from 150 to 500 ft. wide, and it could be traced along a bare mountain range for eight miles. Along the outcrop hundreds of claims were located, but the richest orebodies were found in a few mines in the central portion, within a distance of less than two miles. The total production of the lode was \$400,000,000 in gold and silver. Most of this came from a few large orebodies, called 'bonanzas', five of which had outcrops, some distance apart. The Con. Virginia bonanza, which was shared by the Con. Virginia and California companies, was discovered 1167 ft. underground; it yielded a million tons of \$100 ore and paid \$73,298,700 in dividends within five years, from 1874 to 1879. The stock of the Con. Virginia company sold for \$1 per share in 1870 and for \$780 in 1875. The finding of this orebody was the consequence of the persistent search directed by two stalwart and intelligent Irishmen, John W. Mackay and James G. Fair, who were at the head of an exploration company that worked for two years and spent \$200,000 in a part of the lode that previously had been unproductive. They found other orebodies in other mines. They were well rewarded. Mackay retired with \$20,000,000, and Fair with something over half that amount. They deserved it. Mackay possessed unusual administrative ability and won the absolute confidence of his associates, in fact, of all who came in contact with him. Fair had a genius for finding ore; they used to say at Virginia City, "Jimmy Fair has a great nose for ore". Mackay went to New York and became one of the big men in world finance. He and James Gordon Bennett laid a new cable across the Atlantic and established the Postal Telegraph Cable Company, the control of which rests now in Mackay's son. Mackay was a big man, physically and mentally, a king among men, dependable, self-contained, strong-willed, untiring, but he bore his part in modest and kindly

*Lockhart died at Los Angeles on June 19, 1914. He was 65 years old. His personal property was valued at \$350,000.

fashion. He had no greater pleasure in life than in doing kindnesses. Fair retired to San Francisco and invested his money largely in real estate. Tradition does not record that he was ever 'touched' by his old-time comrades.

The miner is proverbially a man with an open hand, and the successful ones are literally besieged for loans and assistance by old and new friends, until the giver may be forgiven for feeling that they seek him for no other purpose. The observant cynic begins to wonder if there be such a thing as disinterested friendship. This is the saddest part of being a mining millionaire. Such loans are seldom repaid; on the contrary, the "loan oft loses both itself and friends", as Polonius puts it. John W. Mackay, for example, was most liberal to his old friends, and they abused his generosity. He saw it clearly, but his tolerant spirit saved him from misanthropy. A noted gambler, who had known Mackay when they were young fellows together at Downieville, borrowed \$5000 at a time from Mackay and so often that the total reached \$50,000. When he came for the last 'touch', Mackay asked gently, "Say, Joe, what is your limit anyhow?"

It was one of Mackay's chief regrets that fortune separated him from some of his most valued friends, among them Mike Burke. At Mackay's request Mike came from Placerville to San Francisco once or twice, but Mackay's office was so thronged with self-seeking men whom Mike despised that he could not be induced to come again. Mackay used to say, "Mike Burke won't associate with me since I became a millionaire".

Most of the discoverers of mines—and I have known many of them in many lands—have profited but little from their apparent luck. By "profited" I do not mean financially, although not many retained their suddenly acquired wealth for long; I refer to the larger profit of happiness. What shall it profit a man if he gain a bonanza and lose his health, his friends, or his purpose in life? Some of my friends who lived on bacon and beans, on flapjacks and camp coffee for ten or twenty years, and retained a vigorous manhood, succumbed easily to French cookery, to small hot birds and big cold bottles. It is better to be a healthy prospector than a dyspeptic millionaire or even a bilious billionaire. It is the penalty of sudden wealth that it throws a man into a new acquaintance; he loses the good friends of his poorer days, often not from snobbishness or any willingness to be separated from them, but simply because a new and costlier way of living creates a barrier between one set of companions and affords a bridge to another set. Comradeship is largely dependent upon propinquity, similarity of tastes, and the sharing of the same daily experiences. The prospector loses his pals when he moves from the log cabin to the brownstone mansion or the marble hall. Another factor of unhappiness is the loss of a purpose. To the prospector the search for the mine has a zest that goes when once the search is ended; his best moment is the one in which his pick pries loose the chunk of rich mineral or that in which the blast exposes a full stoping-width of

glittering ore. That is the moment of his achievement. To some it is permitted to see the sinking of shafts, the building of mills, and the realization of the dream of a greatly productive mine, but to most this sequel is denied because they have to forego ownership of their discovery. The peak of their curve is the actual finding; after that their portion is flat, stale, and unprofitable. My sympathy goes to the prospector when he is transplanted from the pine-clad mountains of his wide domain to the narrow streets of a crowded city. He is a fish out of water, a bird in a cage, a stranger in a strange land. His happiest moment is not when he has all that he can eat and drink, all the painted women that money can buy, or all the luxury that wealth can purchase. Robert Service has expressed the idea:

"The men who can't remember when they learned to swing a pack,

Or in a lawless land the quest began;

The solitary seeker with his grubstake on his back.

The restless buccaneer of pick and pan,

On the mesas of the Southland, on the tundras of the North,

You will find us, changed in face but still the same;

And it isn't need, it isn't greed that send us faring forth—

It's the fever, it's the glory of the game."

I think of the prospector as having reached the crest of his career when he climbs to the top of the range and looks on the other side, eyes wide with expectation and arms outstretched with eager hope, standing like Balboa "silent upon a peak in Darien", or like Francis Drake, who went forth from the quiet lanes of Devon.

"Not knowing if he went to life or death,

Nor caring greatly, so that he were true

To his own sleepless and unfaltering soul,

Which could not choose but hear the ringing call

Across the splendors of the Spanish Main

From ever fading, ever new horizons,

And shores beyond the sunset and the sea."

Mexico's metal production from 1916 to September 1919, has been published in *Iniciativa de la Ley de Ingresos*. The following table gives the production for 1916, 1917, 1918, and 1919 (January to September). A kilogramme is equivalent to 2.204 pounds.

Metal	1916, kg.	1917, kg.	1918, kg.	*1919, kg.
Gold	11,748	23,543	25,313	17,208
Silver	926,142	1,306,988	1,044,542	1,465,255
Copper	38,411,248	50,983,923	70,253,454	38,170,209
Lead	19,970,986	64,194,752	98,837,154	50,533,765
Zinc	37,449,256	14,757,334	20,098,095	6,199,060
Antimony	828,707	2,646,514	3,208,546	170,778
Tin	292	9,214	13,537	1,588
Tungsten	12,250	187,637	149,480	21,969
Molybdenum			27,371	1,767
Manganese		73,387	2,878,383	2,137,484
Mercury		33,192	163,598	85,399
Arsenic		1,281,820	1,881,011	1,011,250

*January-September.

AMERICAN engineers engaged in reconstruction work have commented on the excellence of French mine-hoists. This machinery is made in France, and probably all the new hoists for the wrecked mines will be built in France, except for such purchases as the French may consider it advantageous to make in Germany.

A Russian Copper Refinery Under Bolshevik Control

By R. G. KNICKERBOCKER

The operation of a refinery in the Ural mountains during the first and second revolution (May 1917 to January 1918) was a difficult task. The disorganization attending the first revolution (April 1917) nearly destroyed all means of transportation of materials or supplies to the Kyshtim refinery, the only one in the largest country in the world. This same disorganized or chaotic condition of a heretofore iron-ruled people soon gave way to the radical Bolsheviks; wages advanced from 2 to 36 rubles for an eight-hour shift; the workman spent most of his time drinking tea and in conference with his neighbor upon the weighty question of how he was to rule his country; the authority of foremen and managers was discarded, and on November 5, 1917, the new government under workmen's, or Soviet, control confiscated all foreign capital and property, and attempted to operate some of the stolen property. It was at this time that the Bolsheviks arrested all engineers at the Kyshtim plant and tried to force them to operate it as they had been doing for the English company.

The Kyshtim estate consists of a timber and mineral tract of land about one-quarter the size of the State of Indiana. On this property the following plants had been in operation: Iron mines and blast-furnaces with foundries at Kaslee connected to Kyshtim by an inland lake; it is 35 miles from Kyshtim to Kaslee. Copper mines and smelter at Karabash connected to Kyshtim by 30 miles of narrow-gauge railroad. Steel-plant, steel-rolling mill, nitric-acid plant, sulphuric-acid plant, dynamite-factory, and copper-refinery at Kyshtim, which is on a branch of the Trans-Siberian railway, 90 miles southwest of Ekaterinburg, the city where Czar Nicholas was supposed to have been murdered in the summer of 1918.

The commercial profit of the entire copper-plant from the mining of the rich sulphide ore to the finished bullion was dependent on low wages and extraordinary richness of ore. No ore was hoisted that ran under 5% copper; no concentrator was used. The fine was charged with coarse ore into the two blast-furnaces; the matte was charged to Pierce-Smith converters and blown to a low-grade metal. This was cast into slabs, 18 in. wide, 24 in. long, and 3 in. thick, and these were shipped to the refinery on the company's narrow-gauge railway. The fume-loss from the converters at Karabash was very high and samples taken from the snow showed good colors. A rough test on this loss gave, over a period of three years, an average of 3% silver and 2% gold. These are percentages lost from the total matte charged to the converters. The American geologist in charge of Karabash informed me that the miners were gouging out pockets of rich sulphide ore with no regard for safety or

the life of the mine; he assured me that the amount of low-grade sulphide was sufficient to more than warrant the mining and treatment of 3% ore.

The Kyshtim refinery consisted of a sulphuric-acid works, anode-furnace, cell-room, electrolytic slime-leaching plant and doré furnace, bullion refinery, and wire-bar furnace. This plant was built by an American engineer, H. Emerich, in 1907. He had not finished the plant as he had planned, and as I saw it in 1917 and 1918 the plant was run down considerably. When I was there a Russian, M. Bredechin, was manager. The converter slab-copper from Karabash was unloaded in the upper part of Kyshtim and carted by one-horse wagons, eight slabs per load, for three miles to the refinery. Here it was weighed, sampled, and charged by means of an air-lift trolley into the anode-furnace. This furnace, with regenerating-chambers, was fired by gas from a crude type of producer using wood refuse, such as tree-tops, pine needles, small branches and bark from the adjacent pine forests, the nearness of which can be seen from the photographs.

These Russian gas-producers have been mentioned by metallurgists as an interesting instance of the use of refuse material for the firing of reverberatory matting and refining furnaces. The matte-furnace at Karabash was also of this type. At Kyshtim producer-gas from this refuse material was fired under boilers, generating steam for power, and also piped to the cathode and anode furnaces, where the combustion was satisfactory and there was never any trouble in keeping up proper heat. It should be noted, however, that the fuel fed to the producer was highly resinous, that the average haul by one-horse wagons or sleds was half a mile, and that the labor-cost at the time this plant was installed was the equivalent of 75c, American currency per day of eight hours for the teamster, who furnished his own horses and wagon. A continuous procession of wagons onto the charge-floor of the producer was necessary owing to the speed of combustion of the fuel. The hearth was 10 by 14 ft. The anodes were cast on a Walker anode-machine rotated by compressed air. Molds of cast-iron were used. The average weight of the anodes was 350 lb.; they were 28 in. wide, 36 in. long, and 1½ in. thick. They were cast thin on account of high contents in gold and silver, and had side lugs for support of the ordinary Walker type. The anode scrap averaged 12 to 20%, and the copper in the anode metal, 98.4 to 98.5%. (Note the difference from standard American anode purity. Traces of arsenic and antimony were present. The number of men employed on the anode-furnace and in loading anodes onto industrial cars and unloading in the tank-house stock-room was approximately 15 to 20 per 24 hours.

The cost per ton of anode-metal for five months (revolutionary times) was 150 rubles, which meant \$75 per ton before the War, but the ruble at this time was worth only about 10 cents. Two-thirds of this cost came from the long haul from the railroad terminal in upper Kyshtim and the poor arrangement for handling the anodes after they were cast; they were stored in a long stock-room on the south side of the tank-house. The crane did not pick up anodes; they were loaded into the refinery cars by a motor-hoist, and the cars were then pushed to one side of the tank-house and the cranes picked them up on a home-made spider. This was an inefficient arrangement, especially when the load on the spider was unbalanced or an anode dropped: the light end went up and the entire load fell. The picking up of anodes from the stock and getting them into the cells took seven men and two cranes approximately four to five hours for every 16 cells or 160 anodes. The starting-sheets, which were of very poor quality, were placed in the cells by hand. They used a platform which rested on the cells and was moved by the crane; this took 10 to 12 men one hour, for 165 sheets. They used a vertical type of centrifugal pump, motor-driven and direct-connected, for circulation; for their upkeep they employed five mechanics, eight hours per day. Three pumps were in operation and nine undergoing repair—a poor arrangement. Later they tried the Pohle air-lift, and will probably use it. Cathode copper and scrap anodes were removed by hand onto cars, and by crane to the track running to the furnaces. Ten men working eight hours on the day-shift removed slime from 10 to 12 cells and carried it to the leaching-room. This operation from start to finish was the worst I ever saw. The crudeness of the method of handling this rich electrolytic slime was evident in the amount of it that was lost both by theft and mechanically. The floor of the cell-room was coated with a layer of slime three to five inches thick assaying 30% silver and 5% gold. The clean-up was as follows: Circulation and power were shut off and the lower cells in the cascade were siphoned off to within three or four inches from the top of the settled slime. A workman, wearing rubber boots and gloves, got into the cells and shoveled the 'soup' into a bucket. The bucket was then carried to a screen-covered filter-box, which stood over the cells, and was emptied onto this screen (the rubber boots and gloves worn by the workman cost in Russia, in 1918, 500 rubles, equal at pre-war exchange, to \$250). This screen, made of copper, was of 10 to 12-mesh and only took out the largest lumps of copper and anode metal. The proportion of copper left in the slime after screening was approximately 40%. This filter-box had a capacity of from ten to twelve cells and when the slime from these was screened into it and the solution filtered through the bottom, the box was carried to the door of the leaching-room and the filtered slime shoveled into a bucket, carried into the leaching-room, and emptied into a washing-tank provided with a filter-bottom. This tank was supposed to be kept covered with a 20-mesh copper screen, but this usually was not done. After washing out the

copper sulphate with cold water, the slime was allowed to settle over-night and the next morning it was transferred to a lead-lined leaching-vat. This vat was rectangular, 3 ft. long, 2 ft. wide, and 3 ft. deep, fitted with a steam-agitator (no cone). When this vat was three-quarters full, which usually took three to four days, a weak solution of sulphuric acid was added to the charge and agitated 12 hours by steam. Then the solution, containing mostly copper sulphate, was taken off by a siphon, three washes by filtration were made, and the slime allowed to settle. It was then removed by shovel and buckets, carried to a wood-fired dryer and dried over a slow fire for three days. Then the slime was put into iron-lined boxes, weighed, and sealed with solder. The weight and date was marked on the box and in the record-book. On 16 amperes in the copper cell-room it took 30 to 40 days to get gold and silver from the anode to the dried slime. No inventory was ever made in this plant. The slime was held in stock for a doré furnace-run. Usually 150 pounds, or 5400 lb., of dry slime was allowed to accumulate before starting this furnace. The hearth (an inverted arch of magnesite) was 4 ft. wide by 6 ft. long, with a drain slope of 3 inches. The tap-hole was at the front, and the metal was run into cast-iron anode molds, 9 in. wide, 14 in. long, and $\frac{1}{2}$ in. thick. This slime was charged dry and melted down, with sodium carbonate and silica as fluxes, by means of two oil-burners of Russian design. Two bad features were the high-pressure oil-burners used and powdery character of the dry slime. The walls of the dust-chamber 30 ft. from the uptake were shot full of doré metal. Most of the oil burned in the dust-chamber and therefore carried the slime along with the flame and fluxed it into the brick walls. The only correction or improvement that could be made to recover this loss, which amounted to 8 or 10% of value charged, would be by means of a better burner of low-pressure type and the Cottrell condensation process, which I advised, but owing to the adverse conditions, this was not done. The doré anodes were transferred to the bullion refinery, sampled by the template system, and the silver recovered by the Moebius electrolytic process, using graphite cathodes. Much trouble was encountered in obtaining a cloth suitable for the basket that held the golden mud. Russian cloth at that time was very scarce, so that sometimes we used soldiers' old uniforms, better known as 'rags', which were sewn together to form the basket. The golden mud was cleansed of silver and other impurities by concentrated nitric acid, then melted and cast into bullion bars of 98.84-99.90 fineness. The silver bullion was 99.95 fine. The proportion of metal loss in the bullion refinery for a period of six months was from 2 to 3½%. One of the most difficult problems that I encountered in the handling of the precious metals was theft. During the month of November 1917, I kept an account of the amount of slime that was recovered from anodes in the cell-room and, together with the foremen at the bullion refinery and the cell-room, we estimated the loss to be approximately \$30,000 in the one month. This loss only covered the process from the anode metal to the end of

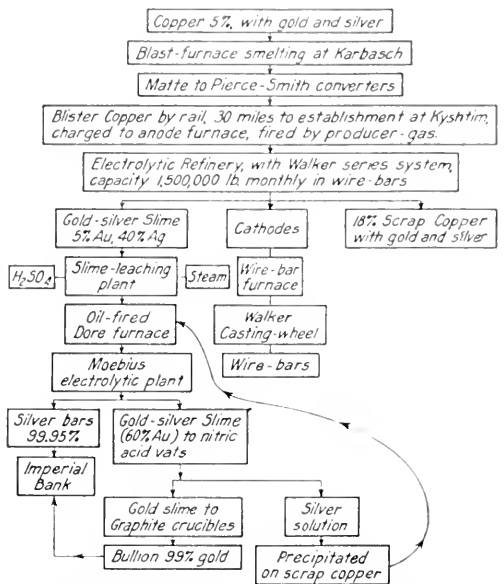

the cell-room: the loss from the beginning of treatment of slime to the finished doré metal was not obtainable, as no inventory had ever been made. These, of course, were extraordinary conditions; the manager himself frankly stated and realized that nothing could be done. It was the beginning of freedom for the Bolsheviks and the ultimate result of the application of the system of government that defines freedom as the privilege of the individual to do whatever he wishes regardless of how it effects his next-door neighbor. I have watched the operation in the cell-room through the skylight, unnoticed by the Russian workmen, in the hours from 1 a.m. to 3 a.m. and ascertained that most of their time was spent in lifting anodes from the cells and scraping the slime into gunny-sacks. They would then carry these sacks of slime back of the refinery building, dry the slime over a crude fire, divide each man's portion, and the next morning walk out each with his share of the night's work.

One evening, about 11 o'clock, a one-horse wagon left the gate-way of the plant loaded down with what appeared to be two standard boxes of leached and dried slime, worth \$10,000. The watchman at the gate stopped the wagon and inquired of the driver what he had in the boxes. The answer was an order to step aside, backed up by a gun. From November 5, 1917, to the time I left, January 25, 1918, the manager of the refinery was not allowed inside the gates, in fact, he took up his quarters 90 miles away at Ekaterinburg. One other thing that I failed to mention, which connects with the operation of the refining-furnace, was the accumulation of side scrap-copper on the cell-walls in the tank-house. This scrap contained \$20 per ton in gold and silver and was charged into the wire-bar furnace—a bad mistake. The lead used in the lining of the electrolytic cell was soft. They informed me they were unable to obtain antimonial lead for this purpose. This soft lead and the inattention of the Russian workmen, together with the pine-wood used in the construction of the cells, caused many leaks of solution and consequent short-circuits, which in turn caused this deposit on the side walls. The cellar of the tank-house was in poor condition. They did not have lead protecting-caps over the glass insulators and the constant dripping of solution had rotted the supporting timbers. In addition, the brick floor had not been coated with asphalt and the solution had percolated to a depth of 6 or 8 ft. below the floor-level. In this connection, and in connection with the loss of slime in the entire plant, the technical commission of the Kyshtim branch of the Union of Technical Organizations of the Ural made an investigation from December 12 to 13, 1917, on the possibility of reducing the loss of slime. The Commission consisted of engineers of the Kyshtim company. Their translated report follows:

"Having discussed the question and inspected the premises the Commission decided that it was indispensable first to carry out the following measures:

1. To establish an accounting of the production.
2. To establish mechanical cleaning of the tanks of slime.

3. To arrange for the illumination of the tank-room cellar independent of existing lighting arrangements.
4. The space under the tanks must be kept closed, and opened for cleaning and inspection, only in the presence of responsible persons, and must be well-lighted.
5. The windows of the tank-house and the slime-room must be equipped on the outside with special grating.
6. Incineration of rubbish from the tank-house must be carried on either in the furnaces used for smelting slime, or in other furnaces in the slime-room.
7. It is essential to place in the tank-house technical foremen for three shifts, at present not existing.
8. The number of laborers working in the tank-house must be reduced to a minimum.

FLOW-SHEET SHOWING TREATMENT OF ORE FROM KARBASCHI

9. The store-room and laboratory must be provided with an entrance not through the tank-house.
10. The accumulation of slime from under the tanks must be stored in the slime department.
11. The space under the tanks should be excavated half again as deep, to a depth of one *arshin* (28 inches) and lined with asphalt.
12. Drying of slime to be done by steam.
13. To construct dressing-rooms for workers in the slime department.
14. Doors in the slime-room should be kept closed.
15. Doors of bullion store-room should be equipped with electric signals.

Also the Commission considers it of the utmost importance to compel workmen in the tank-house to change their clothes. The Commission, considering many of the above-mentioned recommendations to be of an elementary

KYSHTIM, IN

character, cannot but express its astonishment that they have not heretofore been put into effect."

Signed: B. Pentgov, M. Naumov,
E. Richter, A. Ivoilov.

The Commission caused assays to be made of the soil on the floor under the tanks. Results: Soil taken from the neighborhood of the drain-pipes—gold 0.995% ; silver 8.79% ; soil taken near the entrance to the space under the tanks—gold 0.034% and silver 3.2% . Analysis of the rubbish heaped around the furnaces for burning rubbish in the courtyard—gold 0.047% , and silver 0.39% ; gold 0.084% , and silver 0.65% .

This report covers in general the points to which I had referred in my report of September 1, 1917, but it was impossible for any one to attempt any changes, especially in the labor organization. In my final report I strongly advised shipping the converter copper to England and electrolyzing it in a country where law and order was well established.

The normal production of cathode copper in the Kyshtim cell-room for one month was about 1,500,000 lb. This was melted in a small reverberatory furnace with a hearth 20 ft. long by 10 ft. wide, gas-fired with regenerative chambers—the only copper-refining furnace of this type that I know of. The metal was cast on a Walker machine, the usual product being wire-bar of 125 lb. At the time that I was in Russia the copper produced was stored, as the price on the Russian market was below the cost of production at Kyshtim. Most of the copper used by the Russian industry was brought in from the United States.

On November 5, 1917, the Bolsheviks confiscated all foreign property and capital in Russia and endeavored to operate the plants under Soviet direction. At Kyshtim the manager of the old company was allowed to

supervise operations, but under the direct control of the Council of Workmen. The manager was not allowed to draw any money, to make any payments, or issue any orders without the consent or signature of this Soviet; in fact, the only way in which I obtained traveling expenses from Kyshtim to Petrograd was through a trick of the manager's, and this account had to be charged to general expenses at the plant, the Soviet not knowing of the intended use of this money. They arrested all the engineers, and we were under guard night and day. We were not supposed to make any attempt to leave the property or in any way to hinder operations, but to work the same as we had been doing under the company's orders. The obtaining of Bolshevik permission to purchase passage at the railroad office from Kyshtim to Petrograd was quite a complicated affair. I obtained a ticket through an English auditor who was leaving for Petrograd at this time. He had a round-trip permit from the Bolsheviks between Petrograd and Kyshtim and by showing this permit to the clerk at the ticket-office for his passage, and the next afternoon to the station agent, when the clerk was not around, he obtained my passage and we left Kyshtim on Sunday, January 25, 1918. We arrived at Ekaterinburg at 7 o'clock, the same day, and tried to obtain information concerning the through express to Petrograd, but no such information was available and the only thing we could do was to wait at the depot and trust to luck to pick out the right train and force our way into a car. No tickets were sold and the accommodations were gained only by main strength and push. About 9 o'clock that evening we found that our train had arrived in the yard and with our baggage in our hands we endeavored to get on board. By the time we reached the train it was nearly full of peasants and soldiers, and all compartments were locked. We were not able to get into any of these compartments and the

SIBERIA

Kyshtim Refinery

first 24 hours from Ekaterinburg was spent in the aisle standing with the rest of the 'comrades'. The second morning out, an Australian geologist came out of one of the compartments near the place where we were standing, and we slipped into it. There were ten people in this small room, and they were very much afraid of being put out by the soldiers and peasants. Every half-hour or so some one would knock on the door and demand admittance to see whether we had any standing or sitting room. Unless actual force was used each time the door was opened, one or more of these investigators forced his way in. By the time we reached Petrograd there were 27 people in the compartment, which in normal times had accommodations for only four travelers. This crowd consisted of three Russian women, an Austrian geologist, a Finnish dentist from Omsk, an English auditor, and myself; the remainder being sailors, soldiers, and peasants. The only food obtainable during this five day's trip was that which we carried with us. We were not able to get out of the train, because the minute the door was open, we were very likely to lose our seats. We arrived at Petrograd on January 30. The day before there had been a massacre of Russian peasants by the Bolshevik guard. These peasants in some way had antagonized the Red Guards and the guards turned machine-guns on them in front of the Nicholai station, the result being that the next morning the square in front was piled six or eight feet high with dead bodies; in fact, all through the city a common sight was the arm or leg of a human being sticking out from the dirty snow. Horse-feed at that time was also very scarce and many of the cab-horses would drop on the streets, to be pulled to one side and be covered with snow and dirt. It is no wonder that in the spring of 1918 an epidemic of typhoid and other diseases broke out to such an extent in Petrograd. Most of my time in Petrograd was spent in obtaining a Bolshevik *visé* for my passport. This took two weeks.

An ordinary meal, which consisted of a soup and meat order, with coffee and no sugar, without bread and butter, and no potatoes, cost in pre-war currency about \$75. A cake of Hershey's milk-chocolate, which ordinarily sold for 5c. in this country, was worth three rubles and a half, which in our money is \$1.75. Candy was plentiful, but no sugar was to be seen. I was living with an American engineer who had married into a Russian family and had been in Russia for six or seven years; he had two small children; and in order to obtain milk for them, it was necessary for him to go out into the country at the edge of Petrograd, three times a week. This milk cost 25½ rubles (\$12.50) per quart. If one wished to have bread with a meal in a restaurant, it was necessary to buy bread from the Red Guard on the street and carry it to the restaurant. One had to be very careful about being on the street at night, and I can vouch for an incident that happened to an Englishman while I was there. He was on his way home one evening about 11 o'clock and it was necessary that he take one of the dark side-streets. He was wearing an expensive fur coat and before he reached his destination he was held up by two Russian soldiers, or, at least, they wore the uniform of the Russian Red Guard. They demanded his overcoat and one of them put it on over his own coat. The other one then demanded the Englishman's watch and pocket-book. It was about 30° below zero and the Britisher requested that they give him one of their soldier's overcoats, lest he should freeze before reaching home. The soldier who had taken his watch and pocket-book gave him his coat and he went on his way. On arrival home he felt in his pockets involuntarily for his keys and found his watch and pocket-book, which was typical of the childish actions of the Russian in these days of absolute freedom. The Bolshevik had gone to great pains and possibly waited for two or three hours in the cold to hold up somebody, and then, when he had the money and

watch, he forgot them, and gave them back inadvertently to the man from whom they had been stolen. This characterizes the entire Russian Bolshevik movement from start to finish, so that, if it were not for the murder, hunger, and suffering that they cause, the whole thing would be a huge comedy.

The question of Russian paper currency was peculiar indeed. Kerensky had issued a war-time paper currency and the amount of this paper used was increasing every day, so that by the time that the Bolsheviks obtained power there was not enough money. The printing presses were flooded with work. Along with this condition there arose a set of counterfeiters who had a peculiar method of putting their money on the market. They used the same dies and paper that the Government used and issued the same note, with the exception that they printed across the face of each note this statement: "Ours is just as good as yours," and this money was accepted and passed at the same value as the Kerensky issue—a story that is hardly believable and yet goes well with the chaotic conditions of the country. It was impossible to purchase anything with Russian gold or silver, as all this was supposed to be turned in to the Government, and anyone who had gold and silver in his possession was liable to arrest and imprisonment by the Bolsheviks. I remember that I carried 90 rubles in gold in the waist-band of my trousers from Kyshtim to Stockholm. At this time German spies were buying up all the old Russian currency, and money was being made by people in Petrograd by playing the German-Russian exchange market. In the shopping district of Petrograd, it was rare to see any display windows that had a full plate-glass front and all the foreign shops were boarded up to protect the glass from destruction. In walking along the streets, you would notice a large plate-glass window with half a dozen small holes, pasted over with some sort of paper; upon investigating this paper, you found the signature and date of the man who had childishly chosen this as a mark to shoot at.

On February 15, 1918, I obtained my passport from the Bolshevik government and left Petrograd on the Finnish railroad for Helsingfors. I assure you that it was quite a relief to travel on a railway under normal conditions, and with a certain amount of safety. There were no dining-cars on this railway, but one thing that appealed very much to me was the method of serving meals in the restaurant at the station. Upon entering the restaurant, we were given a ticket; the food was obtainable from long tables arranged in what we call 'cafeteria' style; and it was abundant and varied. You helped yourself to all you wished and each paid the same upon leaving. A good meal cost not over \$1. You may be sure that I enjoyed this arrangement after the food-shortage in Russia. Note that this was only 160 miles from Petrograd.

Upon arrival at Helsingfors, Finland, we found that the railway to Stockholm by way of Torno had been destroyed by the Red and White war, which at that time was at its height in Finland. We were advised by the

British consul to get in touch with a British naval captain who was taking an old army transport from Abo to England, by way of Stockholm. We found that the captain had already accommodated 600 refugees, consisting of citizens of Sweden, Finland, Russia, Austria, Germany, France, England, and the United States. He was glad to help us out and assured us that he would try to land us at Stockholm 48 hours after leaving Abo. It was necessary that we take our own food to last us this 48 hours. This we did, and left Abo on Sunday, February 17. The transport had a poor engine and only half a propeller; for this reason we were towed through the thick ice by a Russian ice-breaker. The ice extended about three-quarters of the way to Stockholm, where open water was encountered. Twelve hours out from Abo the Russian crew on the ice-breaker struck for more money, and since we failed to meet their demand, they left us frozen in the ice among the Alland islands. We were here two weeks, and as our food supply was intended only for 48 hours, it was necessary that we make daily expeditions to the little villages on the islands in order to feed 600 people. At last we made arrangements with another ice-breaker to tow us to Marienham island. They were only able to get us to an isolated part of the island and from here we had to sleigh across to the main port and were taken on board a Swedish vessel that landed us at Stockholm on March 4—two weeks and a half after leaving Abo. We found that the next vessel for New York left Christiania on April 11, five weeks later, so we had plenty of time to see Norway and Sweden.

We sailed on the 'Bergensford' from Christiania, Norway, and after a 20-day voyage, which was necessary in dodging submarines and mines, we landed at New York on May 2, 1918.

ROCK SPECIMENS are continually being sent to the U. S. Geological Survey with the request that they be 'analyzed' or 'assayed'. The question is frequently asked "What is the difference between an assay, an analysis, and an expert examination of a specimen of rock or mineral?"—such a specimen as may be sent to the Survey by anyone who has found or thinks he has found a valuable mineral? Ninety-nine out of every hundred specimens submitted to the Geological Survey are found upon inspection to be commercially valueless. Such an inspection or test, however, is widely different from an analysis. A complete analysis of a rock that is composed of many different minerals may require from two to six weeks' time in the laboratory, involving the more or less continual attention of a chemist equivalent to three or four days of his time, and such work is done by the Survey only in connection with its own scientific investigations. An assay, on the other hand, is usually a fire-test made to determine the exact metal content of an ore specimen. The Geological Survey makes no assays for private parties, but does make inspections or simple chemical test and reports the findings to the persons interested.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

CO-OPERATIVE SCHEME OF MINING OREBODIES AT CLIFTON.

BISBEE.—An announcement has been made by Norman Carmichael, general manager for the Arizona Copper Co., and P. G. Beckett, general manager for the Phelps Dodge Corporation, that a joint investigation is to be undertaken at once in the Clifton-Morenci district with a view to determining whether better and more efficient results can be obtained by a plan of joint extraction of the large low-grade orebodies which lie partly in the territory of each company. Under the present existing conditions and method of operations it is conceded that these ores cannot be mined separately to the best advantage, and it is with a view to combined operations that the investigation is to be made.

COURTLAND.—The Leadville Mining Co., at Courtland, which has been working 20 men and shipping ore, has ceased operations pending the return of normal conditions on the railroads. Some lessees on the property are continuing work.

KINGMAN.—The bullion shipments of the United Eastern Mining Co., at Oatman, amounted to \$561,759 for the first quarter. The annual meeting was held at Oatman in March, when the old board of directors were unanimously re-elected. The report of the president stated that \$2,031,594 was the gross value of the ore mined and milled in 1919. The total tonnage put through the mill was 97,325. The ore-reserves as of January 1, 1920, were 269,207 tons of ore having a gross value of \$6,000,820. This is an increase in tonnage over 1919, but a decrease of over \$400,000 in gross value. The present mill-tonnage is about 325 tons per day.

NOGALES.—By a recent verdict in the Superior Court of Santa Cruz county, Frank Powers recovers the half-interest in the World's Fair mine which he agreed to transfer to A. A. Holland if a mill of 100 tons daily capacity was constructed on the property. Holland assigned his interests to James Emery and the late Hiram Whitecomb. Powers contended that the mill was not suitable and did not have the required capacity and asked for cancellation of the contract. A 3½-ft. vein of lead-silver ore has been opened in the old National mine, formerly owned by George Gross, which was taken over the first of the year by the Gold Star Mining Co. The mine is situated in the Patagonia range 14 miles from Nogales. Ten men are at present working at the mine.

Jim Layman, who has spent \$80,000 in development at the Blue Nose mine, has organized the Arizona Pata-

gonia Silver Mining Co. with \$500,000 capital to acquire the property and continue development and erect a 100-ton mill to treat the old dump-ore as well as the ore opened up by the recent development on the 160-ft. level. The 9000 tons of ore in the dump is said to average 23 oz. silver, 1½ copper, and 1½ lead. Recent treatment-tests have been made on the ore and show that it can be worked at a profit.

TOMBSTONE.—W. T. Boyd and associates, who recently purchased the Solstice mine known as the old Winters mine, will commence development work within a few days. This work will be in charge of E. K. Springer. Work is to be done in the old drift where the late owner for the past several years took out a large tonnage of high-grade silver ore. The dump has been leased to the Giacomo brothers.

WICKENBURG.—W. H. Worthington and Grover Hubbel of Wickenburg, who have purchased the Monte Cristo mine, have cleaned out the old workings above the 100-ft. level and have exposed \$100,000 worth of silver ore. The old shaft is down 400 ft. and a large amount of work has been done above the 300-ft. level. A K & K flotation unit has recently been set up and is working with success. A cleaner and second unit will increase the mill-capacity to 40 tons per day and improve the extraction.

WINKELMAN.—The Continental Commission Co. that recently secured a bond and lease from the heirs of Mike O'Brian on the old '79' mine, four miles from Burns station, on the Arizona Eastern railroad, is now developing the mine. Since commencing operations the company has shipped to El Paso seven cars of ore and has eight cars on the way. The ore that is being shipped averages 25% lead, contains a small amount of silver, and occurs chiefly as carbonate in veins in limestone. The orebody is now opened up along the vein for 200 ft. and to a depth of 150 ft. A road to the mine is to be built and machinery erected at the earliest possible moment. On the other claims of the property there are attractive outcrops of wulfenite, vanadium, and desclozite.

Development at the Antelope Peak Mining Co. in the Tortilla mountains 12 miles from Winkelman is progressing. This property was worked for silver 40 years ago. The vein is seven feet wide, all of which is said to be milling-ore. One to four feet of the vein can be mined and shipped direct. The shaft has reached a depth of 440 ft. and development has been done on six levels above the present lowest level. This work has shown the orebody to have an average length of 200 ft. and has yielded

1000 tons of shipping ore. Stopping operations have just commenced, and the shipping ore averages 12% copper.

COLORADO

VINDICATOR CONSOLIDATED OBTAINS LEASES.

LEADVILLE.—Shipments to Chicago of manganese ore from the Leadville mines have been temporarily suspended because of freight congestion in the railroad yards in the Illinois city. The management of the Star continues hoisting and is now storing ore. The A. V. mine, at the foot of Harrison avenue, continues hoisting manganese ore and will resume shipments when the situation is relieved. Plans are under way to resume at the Jason shaft in the Poverty Flats section where a good grade of manganese ore is found. The Leadville Leasing company has purchased a 50-hp. hoisting engine and other equipment for the O'Donovan Rossa mine and development will commence as soon as the machinery is in place. The O'Donovan Rossa has been inactive for years, but rich orebodies are expected to be opened at greater depth. The annual meeting of the Yak Mining, Milling & Tunnel Co. for the election of directors will be held at the office of the company in Denver, on May 18.

CRIPPLE CREEK.—Development by the Vindicator Consolidated company during the first quarter of 1920 was somewhat disappointing in its results, according to information contained in a circular letter mailed stockholders under date of April 25, and it is further announced that the directors "after thoroughly canvassing the whole situation, unanimously decided that it was inadvisable to make any disbursement to the stockholders at this time". The quarterly dividend therefore has been passed. The ore-shoot on the 19th level of the Vindicator was proved for 300 ft. on the Lillie vein, and continued to a height of 70 ft. above the level. Drifting on the 20th level has disclosed ore of excellent grade, but "payable values exist apparently for a length of only 60 feet". Development is continuing on this and four other levels in this virgin section, but none have yet reached the extension of the ore-shoot. Announcement is further made that a five-year lease has been secured on the Victor mine property and five-year leases on all the various groups lying between the Vindicator and the Victor mine, and on the Arvilla group west of the Victor. The royalties are reported to be reasonable and options to purchase a portion of the territory have been secured. The Victor shaft is 1000 ft. deep and is about 3000 ft. north-east of the Vindicator main shaft. Intervening territory will be intersected by a cross-cut from the Vindicator shaft and the several known veins that are thought to traverse this ground will be explored by drifts. Sub-lessees in the old workings of the Victor are reported to be already taking out a good grade of ore. The Vindicator company has two other development propositions, one in the Cripple Creek district and the other in the San Juan section of the State on which work will be started in May.

The Hoosier mine on Tenderfoot hill, formerly owned

by the Grafton Gold Mining Co. has been sold to J. W. Downer and associates, of Colorado Springs, who have taken possession and will, it is announced, start operations shortly. The Hoosier mine is accredited with production by lessees of about \$500,000. The Grafton company was at one time on a dividend-paying basis and paid \$10,000 in October 1899. The deal was made through D. J. Rubridge of Denver, vice-president and treasurer of the Grafton company, since its incorporation in 1896. The consideration has not been made public, but it is understood the deal was for cash.

IDAHO

A CENTRIFUGAL 'GOLD-SAVING' MACHINE.

CLARK'S FORK.—The Clarinda Copper Co. has increased its area to 166 acres and is putting in equipment. It will drive tunnel No. 4 from the base of Howes mountain on the transcontinental highway. The Clarinda property and the Carpey mine at Cabinet were inspected recently by Charles J. Ashbaugh, Martin R. Gunzel, J. P. Delaney, and William Thompson of New York.

ROCKY BAR.—Recently the American Mining & Development Co., of Spokane, obtained possession of the Independence, North Star, and other claims west of town, and between the famous Elmore and Pittsburg properties on the south and the Ghost and Lansome on the north. The company also purchased the old Reeser mill-site and all of the natural flow of water from Bear and Steel creeks.

MURRAY.—The mine of the Giant Ledge company, four miles from Murray, consists of 65 claims, covered with timber sufficient for all needs. A vertical shaft 400 ft. deep, with a cross-cut 120 ft. to the vein, and drifts 750 ft. north and 450 ft. south, are all in ore, assaying from \$8 to \$97 per ton in gold, silver, lead, and copper. Power is furnished by a 22-hp. steam engine or a Pelton water-wheel. The mine is well equipped with a seven-drill air-compressor of Ingersoll-Rand manufacture. A 112-hp. hoist and pumps are run by electricity.

BONNERS FERRY.—Twenty-four miles north-east of here is the Buckhorn mine owned by the Cyanide Gold Co. Five full claims are traversed by two parallel veins about 6 ft. wide. The ore is gold and silver. A 50-ton ball-mill with air-compressor and gasoline engine will be installed in May. The company is using the new gold-saving machine of the Redemption Gold Co., of Spokane. The principle is that of centrifugal force. A quantity of mercury is contained in a bowl and this is rotated at high speed, until the mercury gradually mounts up and forms a thin film around the sides of the bowl. The ore, ground to 100-mesh, is fed into the bowl, reaches the bottom, and it, too, spreads around, working its way up along the whirling mercury film, the particles of gold having a tendency, because of the intense centrifugal force, to edge outwardly through the lighter material and being also of greater specific gravity than the mercury, work into it, while the tailing, having a less specific gravity, climbs up over the rim of the bowl and is forced out through a tube.

MICHIGAN

THE SHORTAGE OF LABOR IN THE MINES.

Houghton.—An opportunity for interesting study of the psychological problems presented by the present labor situation, with especial regard to copper mining in the Michigan region, is afforded in the operations of the Quincy company today. Like every other company in the copper-producing business the Quincy is troubled by a shortage of miners; yet it must maintain a high production of ore or lose money. At the present time it is running very close to the margin between profit and loss. It necessarily has a highly efficient and high-priced organization to keep going. Its only serious loss in employees is among the miners, the men employed in running drills. In No. 2 shaft some idea of this shortage may be obtained from the fact that at present 25 drills are idle during both shifts. Each machine ordinarily breaks a skipload, or 13 tons, per shift. This means a loss of 650 tons in daily output from this shaft alone. Such a serious falling off in all three shafts of the Quincy company means that there must be a further concentration of efforts and a larger per-man output. The Old Reliable is not making a profit now and while there could be a further saving in the cost per ton if the company should shut down one shaft and operate from two shafts only, it is doubtful if that plan would in the end work out advantageously.

The company now is consulting the men as to their attitude on a new plan. It is a proposition to increase the pay of the miners \$1 per shift if they will work an additional two hours. If all the miners now employed would put in two hours more each shift they would then break enough ore to keep the trammers busy and to keep the mills running at more nearly normal capacity. It is surprising to discover that the men do not jump at the opportunity to earn this additional pay. They formerly worked ten hours per day and considered it a fair day's work. Of course they want the additional pay, but most of the men explain that they are getting plenty of money now, that mining with a drilling machine is rather strenuous work, that there is more or less dust from the machines and some of it goes down into their lungs, that they feel they are doing about all they ought to do, and the automobile season is upon them and the car needs attention. It is a fact that the company has not put the proposition formally to the miners but 'feelers' have indicated that they do not think any too well of the suggestion.

MONTANA

LITTLE ORE BEING HOISTED AT BUTTE.

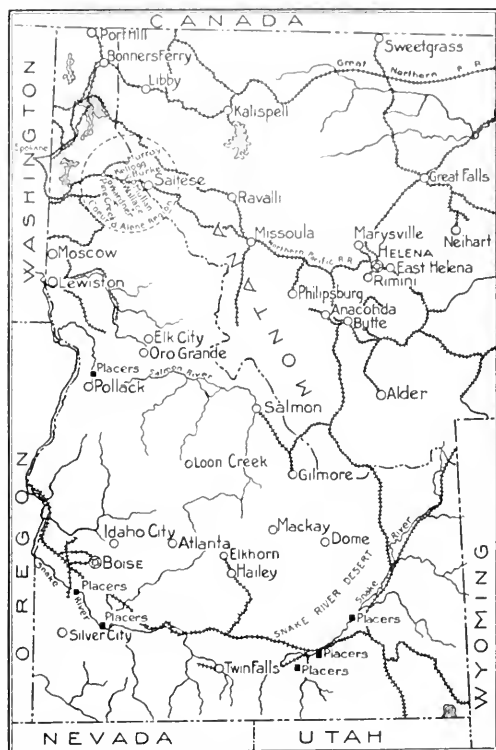

BUTTE.—At the North Butte property drifting has advanced 20 ft. within the highly mineralized Edith May vein on the 3400-ft. level. The lode assays 5% copper and 2½ oz. silver per ton. This is the lowest level of the mine. The 3200-ft. level shows the vein to be 15 ft. wide and to assay 6.2% copper and 3½ oz. silver. Ore from the 3000-ft. level assays 7% copper and 3½ oz. silver.

BASIN.—Steady development work is continuing at the

Jib mine. The 300-ft. level has been cleaned for a distance of 1800 ft. Three stopping floors have been opened on this level in ore having a width of 35 ft. and an average value of \$20 per ton.

LUMBY.—A 3-mile pipeline to the power-plant of the Lukens-Hazel mine is being constructed. The 200-ton concentrator has been completed. With the completion of the two-story bunk-house and the pipe-line the shipment of concentrate will commence. E. Edward Lukens of West Virginia is president.

BELT.—Options on the East Belt coal properties have

MAP SHOWING THE PRINCIPAL MINING DISTRICTS OF IDAHO

been obtained by Boston capitalists. These properties cover 1600 acres of the best coal land in the State. It is expected that 200 to 300 men will be employed shortly.

BUTTE.—The strike situation in Butte has improved considerably. Since the arrival of 300 United States troops, there have been no disturbances either in the city or on roads leading to the mines. There has been a substantial increase in the number of miners reporting for work, but operating conditions are far from normal. Little or no ore is being hoisted. The available labor is being used on shaft-repairs and general plant clean-up. It is estimated that close to 3000 men have left town since the strike's inception.

NEVADA

THE TONOPAH DIVIDE REPORT.

DIVIDE.—The annual report of the Tonopah Divide states in the most important paragraph: "By assuming that the areas exposed on the different levels are representative of the orebodies and making nominal allowance for continuation beyond faces which expose a block only on one side and allowing a normal admixture of waste-rock in mining, the developed and probable first-class ore at this time is 52,000 tons averaging 20 oz. silver and 0.08 oz. gold, containing a total of 1,040,000 oz. silver and 4160 oz. gold. The gross value, at \$1.25 for silver, will be approximately \$1,385,000." This part of the report is signed by E. A. Julian as consulting engineer. H. C. Brougher, president, in his report, says: "Last year's report contained a speculation by A. I. D'Arcy, then consulting engineer for the company, on the amount which would be available in case subsequent work should prove the ore continuous between the different exposures then made. Unfortunately this statement was deliberately misquoted by many to be an estimate of ore then developed and the incorrect statement was given wide publicity." Mr. D'Arcy said in his report: "The mine has not been sufficiently developed to measure the ore-reserves, but as a matter of speculation the openings now existing in the mine, if taken to represent the true average over a width of 21½ ft., a length of over 400 ft., and a depth of 500 ft., would produce 330,000 tons of ore, and if the value as indicated by sampling is taken as \$27.60 per ton, the mine could be expected to produce \$9,108,000 gross." The difference in the reports of the two engineers and the president's explanation, particularly the latter, are regarded as remarkable. While the statement of Mr. D'Arcy may have been 'deliberately misquoted' and while it was a 'speculation', the cutting of this 'speculation' by nearly \$8,000,000 presents a rather peculiar situation, in the opinion of persons interested in the mine. Mr. D'Arcy's report was known to be a 'speculation', but that it was subject to a variation of \$7,723,000 was not the sense in which the former consulting engineer expected it to be understood. Well informed persons did not take Mr. D'Arcy's report to be an 'estimate of ore then developed', but they did think that it was not to be taken as an indication that months of additional development might show his \$9,108,000 'speculation' to be an over-estimate of \$7,723,000. During 1919 the company shipped to the MacNamara mill in Tonopah 9612 tons of ore which was treated with a net recovery of \$254,950. The operating costs were \$194,409, leaving a net realization of \$60,541. A total of 7578 ft. of development work was performed to December 31, 1919. The 'gold' vein was cut on the 370-ft. level, but it only 'crossed several seams which showed uncommercial values. A drift has been extended 40 ft. on the best looking seam, but with negative results'.

FAIRVIEW.—The Broken Hills Silver corporation, newly organized, has taken over the Broken Hills group of seven claims, 15 miles south-east of Fairview. The claims have been developed through a 150-ft. shaft by J. M.

Stratford and J. H. Arthur, who located them in 1913. Lateral work has been done at 50, 100, and 150 ft. There are three other shafts and the vein, of an average width of 4 to 5 ft., has been opened for a distance of 550 ft. The vein is on the hanging wall of a mass of andesite more than 75 ft. wide, which has never been cross-cut, and engineers think the foot-wall side offers great possibilities. Stratford and Arthur have shipped through Fallon, 70 miles distant, 400 tons of ore of an average value of more than \$100, a sorted product. The average width of the vein on the 150-ft. level is 8 ft. and the average metallic content is 18.51 oz. silver and 0.06 oz. gold. The value of the ore exposed in all workings is estimated to be \$175,000.

COPPER BASIN.—Lumber for additional buildings is being hauled from Battle Mountain to the Buckingham and it is planned to work from 25 to 30 men during the summer. The shaft is to be sunk to 500 ft. from the present depth of 200 and the Northland and Midland drift tunnels are to be extended. A new hoist and an air-compressor will be erected. There is a good tonnage of silver-lead ore exposed and if the work planned produces satisfactory results a treatment-plant will be built. Some of the ore is rich and at two places in drifts from the shaft 5 ft. assaying \$150 in silver, gold, and lead is exposed. The ore contains 200 oz. silver to one of gold, with a lead content varying from 5 to 10%.

GOLD CIRCLE. Supplies are being brought into the district for the resumption of work on the Queen. The main shaft is to be sunk 100 ft. from the present depth of 230. At 130 ft. the shaft entered a fault. Sinking was continued through the fault to 180 ft., where a cross-cut opened ore. Sinking was then resumed and ore was found in the shaft last October, with the vein in better condition than above the fault and assaying \$25 in gold and silver for a width of eight feet. The Elko Prince is developing important ore-shoots on the 600-ft. level of the 950-ft. shaft and the 40-ton cyanide mill operated throughout the winter. The mill was started late in 1915 and since then it has produced nearly \$2,000,000 in bullion. The Big Chief Consolidated is reported to be planning the erection of a cyanide-mill to treat ore from the Missing Link and Jackson claims, where a large amount of work was done during the winter by a crew of 16 men who developed ore of milling grade.

CACTUS.—A cross-cut that has been driven 20 ft. into the vein at a depth of 265 ft. in the Cactus Nevada has exposed 16 ft. of silver ore of an average value of \$15. The vein is from 75 to 100 ft. wide, with the best ore occurring on the walls. The important feature of the work at this depth is that the vein is in much better condition than on the 116-ft. level. Sinking of the shaft from 265 ft. has been started and another cross-cut will be driven at the 365-ft. point.

TONOPAH.—The labor situation in Tonopah and Divide is nearly normal. The mine operators and merchants have declared war on the I. W. W. element, which is held responsible for the two recent strikes.

NEW MEXICO
CHINO COPPER CO.

HURLEY.—During 1919 the Chino Copper Co. drilled two development holes with a combined depth of 921 ft., which brings the total footage of such work up to 265,672. Since the beginning of operations, the mine at Santa Rita has produced a total of 19,716,650 tons of ore, averaging 1.86% copper, and the reserves as of January 1, 1920, are estimated at 94,781,525 tons, averaging 1.62% copper. The total quantity of stripping removed from the mine during the year was 3,161,381 cu. yd., bringing the total quantity of stripping removed since the beginning of steam-shovel operations on September 23, 1910,

pared with 0.109c. for 1918. The value of the copper produced during the year was \$7,308,597, and of gold and silver \$17,928, making a total of \$7,326,525. The net income was \$1,301,797, or \$1.50 per share, as compared with \$3,908,222, or \$1.49 per share in 1918. The average price received for copper delivered during 1918 was 18.784c. per pound. Dividend disbursements during 1919 were at the rate of \$3 per share, or \$2,609,940. The grand total of such disbursements to the end of 1919 was \$29,012,982. Metallurgical research has progressed sufficiently during the past year to indicate that the problem of a more profitable treatment of partly oxidized ores on a commercial scale is approaching a satisfactory solution.

THE UNITED STATES SMELTER AT MIDVALE, UTAH

to January 1, 1920, up to 27,025,136 cu. yd. The cost of steam-shovel mining and stripping combined during 1919 was 64.91c. per cubic yard, as compared with 69.55c. for 1918 and 33.97c. for 1915. The mill at Hurley treated 1,765,200 dry tons of ore during the year, as compared with 3,836,400 dry tons for 1918. The average copper content of the ore during 1919 was 1.82%, or about 0.2% higher than for 1918. The production of concentrates was 128,154 dry tons, averaging 16.5% copper. The average cost of milling was \$1.56 per ton, being an increase of 19c. per ton over the previous year. During the year there was shipped direct to the smelter 34 tons of copper precipitate, containing 22,721 lb. of copper. The total production of copper from all sources during 1919 was 42,325,449 lb., as compared with 79,340,372 lb. for 1918. The average cost per pound, excluding charge for Federal income and profits taxes, and without credit for precious metals recovered and miscellaneous income, was 15.53c., as compared with 14.13c. for 1918. Credits for gold and silver and miscellaneous income for 1919 were equivalent to 0.216c. per pound of copper produced, as com-

In August 1919 tailing air-lift equipment was put in operation. This raises the tailing approximately 40 ft., giving the necessary elevation to carry it to the new lower tailing storage by gravity. This scheme, while a departure from ordinary methods of elevating tailing, has demonstrated operating economy and has affected a substantial decrease in the cost of tailing disposal. Throughout the year operations were conducted on approximately 50% basis.

UTAH

CURTALMENT AT EUREKA AND PARK CITY.

BINGHAM.—Recent work at the Victoria mine of the Bingham Mines Co. has been highly gratifying, according to Imer Pett, general manager. A sub-level from a winze sunk below the 1300-ft. level has disclosed over 60 ft. of high-grade ore. It is probable that this ore will be extracted from the adjoining Dalton & Lark workings, and a connection with one of the latter company's drifts is now being made. During January, the net earnings from this property were \$9758; during Febru-

ary, \$17,720; while the March earnings are estimated at \$20,000.

PARK CITY.—The district suffered more than any other in the State as a result of the strike of railroad switchmen, not a car of ore being shipped during the week ending April 24. As a result the mines here have accumulated approximately 2000 tons of ore which normally would have been shipped during the week. This is the first time since the strike of miners in June 1919 that no shipments were made from the district. Paul Hunt, superintendent of the Park-Utah property, reports conditions improving in the mine. A small vein of first-class ore is being followed, which it is expected will develop into a commercial body before long. A considerable tonnage of low-grade ore has been developed, with frequent seams running high in silver and lead. The new pump at the Iowa Copper mine is working satisfactorily, and progress is being made in dewatering the shaft and drift on the 200-ft. level. It is expected that mining operations will be resumed in the face of the drift early in May.

A contract has been awarded to the Diamond Drilling Co. of San Francisco for extensive drilling at the property of the Three Kings Consolidated Mining Co., according to P. J. Mackintosh, general manager. It is the intention of the management to continue exploration work by this method, and to locate definitely the Weber quartzite contact from the bottom of the winze on No. 4 fissure. This fissure was intersected by the main cross-cut on the 500-ft. level, a distance of approximately 1000 ft. from the main shaft. The management has decided that it is necessary to explore this contact as quickly and thoroughly as possible.

EUREKA.—While mines in this district were supplied with some cars during the week ending April 24, not enough were furnished to handle more than one-third of the regular weekly production of the district. The Salt Lake & Los Angeles railroad, which handles most of the ore from this camp, was unable to supply a single car, and the mines had only the cars for loading that were furnished by the Denver & Rio Grande railroad. Mines in the south end of the district were unable to secure cars. As a result the men employed in the Mammoth and adjoining properties were taken from ore production and put on development, where they will be employed until the railroad situation is cleared up. The Chief Consolidated was handicapped by the car-shortage and compelled to lay off some of its men.

No work is being performed on company account at the property of the Colorado Consolidated, all of the levels now being turned over to lessees. The work which the Knight interests were doing for the benefit of the Sioux and Empire mines, operating from one of the lower levels of the Iron Blossom, has been discontinued for the present. However, the work being performed in the Empire mine through the Lower Mammoth shaft has not been interfered with. E. R. Higgensen, who several months ago secured a lease on the old Sunbeam mine and has been actively working it during the meantime, mined

fifty cars of ore, all but five of which have been sent to the Tintie mill. Mr. Higgensen states that up to the present, all ore has been taken from workings above the 300-ft. level, but in the near future operations will be started on the 350-ft. level, where there are indications of ore. Owing to the large amount of work required to re-timber the old shaft and clear the workings, mining has not progressed as rapidly as was expected, but within a week, the shaft should be re-timbered to the 350-ft. level.

The new shaft at the property of the East Tintie Coalition is now at the 200-ft. level. Slow progress has been made of late, owing to the fact that but one shift has been employed.

The Griggs Huish Leasing Co. has closed a deal for a four-year lease on the milling plant of the Godiva Mining Co., which it proposes to remodel and put into running order with as little delay as possible. At the time this company was launched, it was generally understood they would take a lease on the May Day mill, but plans were changed owing to the Godiva mill being much larger and already containing most of the machinery that will be needed. New crushers and vanners have already been ordered, and C. C. Griggs, manager, is confident that the plant will be in running order within six weeks. A contract for the erection of ore and concentrate bins has been let to Alex Mattson. Officers of the Griggs Huish Co. are: C. C. Griggs, president and manager; J. Fred Johnson, vice-president; C. E. Huish, treasurer; George T. Castleton, secretary.

ALTA.—Operations at the Logger mine in Big Cottonwood canyon, suspended during the past few weeks owing to severe weather, have been resumed, according to R. D. Maxfield, president. Recent sampling in the face of ore in the south drift showed 0.06 oz. gold, 2.7 oz. silver per ton, and 31% copper. The mine never was in better condition than at the present time, according to Mr. Maxfield. Service over the Utah Power & Light Co.'s line from Big Cottonwood canyon to the Emma mine was resumed on April 27. Since this line was taken out by the big snowslide, the Emma property has been getting power over the Wasatch Mines' line. This was only enough to keep the water in the Emma shaft below the 200-ft. level. Now the normal power service has been resumed, the shaft can be speedily unwatered.

BRITISH COLUMBIA

THE 'ONE BIG UNION' IS ACTIVE.

NELSON.—The 'One Big Union' is again fomenting trouble among the miners, and, at the time of writing, it looks as though work at most of the large mines in the Kootenay will be discontinued. The union demands an increase of \$1 per day in the pay of both miners and laborers, the present schedule being \$5.50 for miners and \$5 for laborers, and that the companies shall provide white sheets and pillow-cases at their boarding houses. At a meeting of mine-owners at New Denver, it was decided to deny the union's demand, and already the miners at three mines near New Denver have been called out. Other districts are likely to be affected in which

event a considerable reduction in production will result. Recently the Consolidated Mining & Smelting Co., that is operating a number of mines in the Kootenay district, raised the pay of all its employees 50 cents per shift, and on April 15 it put into force a scheme of life insurance by which the employees who have been in the service of the company for six months are insured with the Sun Life Assurance Company of Canada for \$500. This sum will be increased \$100 for each six months service until it reaches a maximum of \$1500. It is an open secret that labor trouble that was known to be brewing was the cause for the cessation of work on the 1500-ton concentrating plant that is to be erected at Trail for treating the ores from the Consolidated company's Rossland mines. The ground had been broken and the cement and steel had

ginger, discussing conditions in northern British Columbia, says that, although there is much excitement over mining prospects in this section and notwithstanding that this sentiment appears to be justified to some extent, there are as yet only three proved mines of note. These were the Dolly Varden at Alice Arm, the Engineer in the Atlin district, and the Premier of Salmon Arm. But these are great properties. He continues: "The Engineer, at Carcross, is a proved gold mine and will operate this year if the will of the late Captain Alexander, who was the owner, is executed. Shipments from this mine would be made by water to the White Pass railroad where ore would be taken by rail to Skagway and thence south to the smelters. This mine will have the same effect in making Atlin an active town as the Premier and the

MILL AND OFFICE BUILDINGS OF THE NACOZARI CON. COPPER CO., SONORA, MEXICO

been ordered, when the threatened labor trouble stopped further operations.

SLOCAN.—Three lessees, who are operating the Utica mine, have struck rich ore about 500 ft. from the mouth of the tunnel. The vein is $5\frac{1}{2}$ ft. wide and from eight to ten inches on the foot-wall is heavily impregnated with wire and plate-silver, which carries some gold. The remainder of the vein is a dense mixture of gray copper and galena, with the gray copper predominating. During the year that these three miners have had the property, they have netted nearly \$75,000, and it looks as though they would add another \$25,000 to that sum before the expiration of their lease, on June 1. Two feet of galena is reported to have been struck at the Silver Bear property, on Kaslo creek. W. E. Newton, who is managing the Silver Bell for the Green brothers, is starting operations with 12 men. The force will be increased to double that number as soon as suitable men can be found.

STEWART.—George Clothier, Government mining en-

gineer, discussing conditions in northern British Columbia, says that, although there is much excitement over mining prospects in this section and notwithstanding that this sentiment appears to be justified to some extent, there are as yet only three proved mines of note. These were the Dolly Varden at Alice Arm, the Engineer in the Atlin district, and the Premier of Salmon Arm. But these are great properties. He continues: "The Engineer, at Carcross, is a proved gold mine and will operate this year if the will of the late Captain Alexander, who was the owner, is executed. Shipments from this mine would be made by water to the White Pass railroad where ore would be taken by rail to Skagway and thence south to the smelters. This mine will have the same effect in making Atlin an active town as the Premier and the

SHEEP CREEK.—Harold Lakes, superintendent for the Nugget Gold Mines, Ltd., reports that the old Motherlode mill is ready to commence the season's work as soon as a shipment of cyanide, now on order, arrives. Recently efforts at the mine have been concentrated on the laying of track, the construction of chutes, and otherwise preparing for production. Mr. Lakes reports that the drift on the main vein at a depth of 625 ft. has developed ore for a total distance of nearly 200 ft. Drifts driven both to east and west are still in ore. While the width of the vein varies the grade of ore is maintained.

ONTARIO

RICH ORE AT BOSTON CREEK.

BOSTON CREEK.—Electric power has been turned on at the Miller Independence mine, where the two transformers have a combined capacity of approximately 1000 hp. The central shaft has been completed to the 500-ft. level, where cross-cutting is being done to cut the downward continuation of the rich orebody developed in the inclined shaft. Tests made at Toronto University on samples of rich ore have shown that the telluride which the ore contains in large quantities is of the highest grade, known as 'calaverite'. At the Kennedy-Boston, where the main shaft was put down 100 ft. by hand during the winter, a mining plant is being erected. Sinking will be continued to 150 ft., at which level the main vein will be opened up.

PORCUPINE.—At the Davidson Consolidated the drift on the 500-ft. level has been advanced for 480 ft. from the shaft, the vein showing a width of 40 ft. of ore. Diamond-drilling will be undertaken from the 500-ft. level to explore a new vein, believed to parallel the main lode. The Hayden-Porcupine and Sovereign Porcupine companies are making arrangements to resume work. At the Sovereign property over 4000 ft. of diamond-drilling was done last year and a heavily mineralized vein was discovered and stripped for 45 ft., work being discontinued when the winter set in.

BEAVER HOUSE LAKE.—The Argonaut gold mine has made a shipment of several hundred ounces of bullion to the Ottawa mint. Vein 202 has been opened for over 170 ft. and has yielded a good grade of ore varying in gold content from \$11 to \$23 per ton. Drifting is being undertaken toward a porphyry dike, where diamond-drilling has indicated richer ore at a depth of 250 feet.

COBALT.—The Mining Corporation of Canada is starting its improved plant for the treating of tailing pumped from Cobalt lake. The material from the pumps will be classified over Dorr machines, the slime being cyanided and the sand carried by aerial tram to the plant, which has a capacity of about 450 tons daily. The pumps will handle 1000 tons per day, the surplus being stored for treatment next winter. About 400,000 tons of sand is still to be reclaimed.

At the 425-ft. level of the Chambers-Ferland mine of the Aladdin-Cobalt Co. a vein four inches wide and composed of calcite and smaltite has been opened in which the silver content has been found to vary from \$5 to \$1000 per ton. During March shipments of ore from other parts of the mine were maintained at about 30 tons per day, resulting in a substantial margin of profit, it being officially stated that the ore averaged \$26 per ton.

The Beaver Consolidated has secured a lease on the adjoining Prince property. The deal is the result of the Beaver having followed a four-inch vein up to the boundary of the Prince claim at a depth of 1100 ft. The lease provides an even division of the 'net' profits derived from the operation.

Robert Lyman, manager of the Sence Superior mine

during its brief but profitable career, has secured a lease on the Rochester property, and is concluding plans for exploration by using the shaft on the adjoining Lumsden mine, from which a cross-cut extends onto the Rochester at the 300-ft. level.

It is announced that within the next week or so the McKinley-Darragh will resume work with its oil-flotation plant which was closed in January owing to the difficulty of treating tailing from the bed of Cobalt lake during the winter weather.

MEXICO

MINA MEXICO MILL TO START.

AGUA PRIETA.—Messrs. Hayes, Horkins, and Munoz of the Mina Mexico staff, have arrived here from El Paso, preparatory to operation of the mill on the property, which was expected to start April 30. Placing of the flotation machinery and remodeling of the old concentrator have been completed. It is expected to send out about 150 tons of silver concentrate, or about five carloads, monthly to El Paso. For the present, it is understood, the greater part of the ore passing through the mill will come from the old dumps.

John W. Ammerman and associates, of Kansas City, who are directors of the Sonora Development Co. with valuable properties in the vicinity of Pílares de Nacozari, visited Agua Prieta recently to investigate conditions. Mr. Ammerman and a geologist from Patagonia, Arizona, visited the properties.

CANANEA.—The rail strike has not seriously affected this camp and according to statement of George Young, secretary-treasurer of the Cananea Consolidated Copper Co., a plentiful supply of all necessities is on hand for the present. Tyndall Evans, general manager for the company, accompanied by Mr. Young and his private secretary, Charles L. Montague, went to Agua Prieta on April 22, holding a conference with General Calles, the nature of which was not made public. According to recent announcement of the American consulate at Nogales, the withdrawal of the garrison from Cananea recently caused the American residents there to apply to the State government for permission to arm themselves and form a civic guard. Soon after the request had been made, however, a new garrison of 50 soldiers arrived to police the camp.

CUMPAS.—H. J. Glennon, manager of the Nacozari branch of the Phelps Dodge Mercantile Co., has taken a lease on the Belon property, situated in the vicinity of Cumpas. He will start development and mining operations soon. Large orebodies have been developed in the property by former operators but in recent years it has lain idle owing to unstable conditions.

LAMPASAS.—J. B. Barney, in charge of the Lampasas mine for several years, reports that the mine is not producing at present, the lack of water making it necessary to close down the mill. Fuel also has to be hauled seven miles over a rough trail. Efforts are being made to overcome these handicaps and operate the mine.

ARIZONA

Tucson.—The Arizona Tonopah Mining & Milling Co., whose property is in the Amole district, nine miles southwest of here, recently found gold, silver, and lead ore in No. 3 shaft and in east and west drifts valued at \$73 per ton. The ore from this shaft from the surface to the 100-ft. level averaged \$27.50 per ton. The three-compartment shaft has reached a depth of 145 ft. George Ankers is general manager.

CALIFORNIA

Amador County.—Bulletins have been posted announcing an increase of 50c. per shift for all days-pay employees of the Plymouth Consolidated Gold Mines, Ltd. The bulletin states that the increase is given in an effort to offset the high cost of living, which the company realizes is abnormal, and it promises that the increase will stand while present conditions continue. The cost of operation has increased \$2 per ton in the last two years, and the men are urged to give their best efforts to increase production. The same increase has gone into effect in all of the mines controlled by W. J. Loring and associates, which include the Morgan at Carson Hill, and the Calaveras at Melones. The new scale makes the wages of the muckers \$4 per day and those of miners \$4.50.

COLORADO

Alma.—The lessees of the Champaign mine will resume operations in May and R. H. Baxter and associates soon will be operating the Wheeler mine. Operations on the Champaign were suspended in January of this year, when a shipment by express, to the American Smelting & Refining Co.'s plant at Pueblo, returned 3.10 oz. gold, 894.1 oz. silver, and 14.9% lead. At the Wheeler mine Mr. Baxter reports that there is a 10-in. streak of ore in the back of the drift just beyond the breast of the tunnel, which is in virgin ground that assays 0.78 oz. gold, 8.43 oz. silver, and 43.8% lead.

IDAHO

Bellevue.—George Wyman of Boise, representing the company which has recently purchased the old dumps of the Queen of the Hills and Minnie Moore mines, states that the company will erect a mill on the property and use a flotation process for the recovery of the sulphide constituents of the ore.

Idley.—The War Dance mine has cut another rich vein of lead-silver ore at a depth of 300 ft. After being intersected the vein was followed 100 ft., the last 40 ft. of the drift being in good milling ore. The old War Dance is credited with a yield of more than \$300,000 to pioneer operators. The ore runs about 70% lead, with 70 oz. silver per ton.

MISSOURI

Joplin.—What is probably a record in rapid shaft-sinking in this district has just been made at the High Five mine at Waco, where the fourth shaft has been completed to a depth of 150 ft. in the fast time of three weeks and five days. The shaft was sunk by B. Smith and A. Sease, expert men, working double shifts. No previous record of shaft-sinking, reported from any part of the district, equals this. Good ore had been discovered by drilling and a drift is being driven

to connect with the new shaft. This development makes certain a continuance of production at the High Five mine.

Two excellent finds of lead ore in the Webb City district are reported, one on the Hough land south of town and the other on the Troup tract at Prosperity. The Community Drilling Co. which has been prospecting the land for several weeks cut ore that is said to rival the Connor body opened by the company several months ago. Lead ore of exceptional richness in the new prospect was found at a depth of 50 ft., running through a 10-ft. stratum. Then at a depth of 100 ft. it was again penetrated for 30 ft. The discovery of rich lead ore on the Troup land was made by George and Fred Kusterer who are proving the land for themselves.

NEVADA

Battle Mountain.—The Buckingham Mining Co. reports that the Midland tunnel has intersected a new vein containing native copper and silver. The property is situated at Copper Basin. The Midland tunnel is in 360 ft. and will be driven a total distance of 3700 ft. to develop orebodies opened on the south side of Giant mountain. Orders are to be placed for a hoist, compressor, and drills. M. Burge is manager.

Pioche.—The experimental tailing-treatment plant recently erected at Bullionville, for the purpose of making experiments on the dumps there, has proved a success. A recent run included 19 tons of ore over two tables in a 24-hour period. Operations are under the supervision of G. E. Bate-man, who is acting for San Francisco capitalists who have obtained a lease on the tailing owned by the Prince Consolidated company at the old Bullionville and Dry Valley plants. The experimental plant is equipped with one Vanner and one Overstrom table. From the 19 tons of tailing 1800 lb. of concentrate was obtained, this product assaying 35 oz. silver, 45% lead, and about \$5 in gold. The experiment will be carried further in order to determine the exact equipment which will be required to treat 100 tons of ore per day. The results of this experiment will affect the entire mining industry of Pioche. If it proves as successful as at present indicated the dump of every mine in the district may be made sufficiently valuable for further working.—George Snyder, manager for the Black Metal company, reports the shipment of 30 tons of high-grade ore to the smelter at Salt Lake. He expects the ore to average \$250 per ton in net returns. This ore, according to Mr. Snyder, was taken from the 25-ft. north stope. An average daily output of 75 tons is being taken from the mine.

Pioneer.—At a depth of 600 ft. the sulphide zone has been entered by the shaft of the Reorganized Pioneer Co. The discovery is considered the most important yet made in southern Nye county. W. J. Tobin, president, has arranged for the purchase of additional equipment preliminary to cross-cutting to pick up the extension of the Pioneer vein. — Operations have been resumed at the Consolidated Mayflower which is now under the control of W. J. Tobin and associates.

Reservation.—The tunnel of Review Silver Mining Co. has advanced 30 ft. and is expected to reach the junction of the main silver-lead vein and a gold-silver cross-vein soon.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

A. W. Allen is in Chile.

Walter G. Perkins is in London.

M. E. Merrill is at Los Angeles.

Walter Harvey Weed is in Cuba.

Charles O'Brien has returned to San Francisco from the Philippines.

Karl Eilers has opened an office in the Woolworth building, New York.

J. B. Annear has moved from Merced, California, to Bonanza, Colorado.

E. C. Bloomfield is now with the Burma Mines company at Namtu, Burma.

E. Gylbon Spilsbury has moved his office to 132 Nassau street, New York.

H. R. Bischoff, of the Bluestone mine, Mason, Nevada, is at Stillwater, Minnesota.

George H. Ryan, of Eureka, Utah, has taken a lease on a zinc property near Ely, Nevada.

G. Perry Crawford sailed from New York on May 15 for London, on his way to Spitzbergen.

A. B. Frenzel passed through San Francisco this week on his return from Arizona to Denver.

Thomas B. Stearns was in San Francisco last Wednesday on his return from La Jolla to Denver.

Alvin B. Carpenter, of Los Angeles, was in Plumas county examining copper prospects last week.

Harai R. Layng has been appointed superintendent for the Eureka-Holly Mining Co., at Eureka, Nevada.

R. P. Sharpe, of the Ripsey Copper Co., has moved to Indianapolis, Indiana, from Miami, Oklahoma.

A. J. McNab, manager for the Mason Valley Mines Co., has moved from Thompson, Nevada, to New York City.

Edwin E. Chase and his son, R. L. Chase, of Denver, are examining mines in the Magdalena district, New Mexico.

C. R. Morris, mill superintendent for the Mexican Mining Co. at Virginia City, Nevada, was at Salt Lake City recently.

F. G. Janney, general superintendent of mills for the Utah Copper Co. at Garfield, Utah, has returned from New York.

E. J. Franklin, consulting mechanical engineer for the Ray Con. Copper Co. and Chino Copper Co., is at Salt Lake City.

J. B. Tyrrell, of Toronto, has been appointed consulting engineer in Canada for the National Mining Corporation, of London.

W. W. Wishon has been appointed consulting engineer to the McCracken Silver-Lead Mines Co., in Mohave county, Arizona.

Francis B. Lawson (Major), chairman of the Mountain Copper Co., was in San Francisco this week, on his return from the Orient to London.

Tage Thomasson, metallurgist associated with several mining companies in Sweden, is visiting mines and metallurgical plants in Utah and Montana.

C. H. Abeling, formerly with the Stimpson Equipment Co. of Salt Lake City, is now mill superintendent of the Vipont Silver Mining Co., near Oakley, Idaho.

M. J. Gavin, refinery engineer to the U. S. Bureau of Mines, with headquarters at the Salt Lake station, spent several days during April in California.

Van. H. Manning, Director of the U. S. Bureau of Mines, has resigned to become Director of Research of the newly organized American Petroleum Institute.

S. Funakoshi, mining engineer with the Kuhara Mining Co., Ltd., of Tokyo, accompanied by Takio Shikamura, a

mining engineer connected with the Phelps Dodge Corporation for the past ten years, has been visiting mines and metallurgical plants in Utah.

Frank Anderson, mining engineer of Salt Lake City, has been appointed U. S. Mineral Surveyor of Arizona, by Frank B. Trott, Surveyor-General of that State.

Ross E. Douglass has resigned from the service of the Braden Copper Co. in order to form a partnership with A. H. Lawrence, with headquarters at Santiago, Chile.

A. W. Lehmann, manager for the Catame Copper Co. in Chile, is making a tour of the principal mining districts of the United States. He spent several days in Utah recently.

T. P. Billings, who has been mine engineer for the Bingham Mines Co. and the Eagle & Blue Bell Co. for 12 years, has been promoted to the position of general superintendent.

Cecil J. Brooks, metallurgical engineer engaged in research work in Sumatra, is making a tour of mining centres in the United States. He spent several days in Utah recently.

J. E. Spurr, editor of the 'Engineering and Mining Journal', delivered an address before the Michigan College of Mines, on April 14, the occasion being the graduating exercises.

J. H. Wiggins, assistant engineer to the U. S. Bureau of Mines, who has been stationed at the San Francisco office for the past six months, has returned to his headquarters at Bartlesville, Oklahoma.

R. E. H. Pomeroy, smelter superintendent at the Steptoe Valley smelter at McGill, Nevada, has resigned. On June 1 he will become associated with the Bonnot company, manufacturers of coal-pulverizing machinery.

E. C. D. Marriage, proprietor of the Pioche assay-office, was at Salt Lake City recently, on his way to his old home at Hatfield, England, on a visit. During his absence, Earl T. Godbe will have charge of the assay-office.

Charles Gammon, assayer in charge of the United States assay-office at Salt Lake City, has been promoted to the position of chief assayer in New York. Hugh T. Rippeto has been named his successor at Salt Lake City.

J. Fred Johnson, mine superintendent for the Chief Consolidated Mining Co. at Eureka, Utah, has been elected a director of the company to fill the place made vacant by the death of William P. Seager, of Houghton, Michigan.

Obituary

John S. MacArthur, the inventor of the cyanide process, died at Glasgow, Scotland, on March 16.

Oliver Sheppard Picher, president of the Eagle-Picher Lead Co., died of pneumonia, at his home in Winnetka, Illinois, on April 26. He was primarily a business man, and as such his judgment and ability found expression in the business that stands as a monument to his talent. He did not stop short of mastery of each detail of every department; he was an accountant, a metallurgist, a mining engineer, a chemist, a manufacturer, a financier, and his personality brought him thousands of friends in the business and technical world. He was born at Springfield, Missouri, but spent his boyhood and youth in California. He was a graduate of Leland Stanford University and the Columbia Law School. After finishing his law course he spent three years in the office of Elihu Root. Later he went to Joplin, Missouri, where his father, Judge O. H. Picher, was president of the Picher Lead Co. In 1906 he became secretary for the company, a position which he held for three years, until he was elected president. In 1916 the Eagle White Lead Co. and the Picher Lead Co. were merged into the Eagle-Picher Lead Co., and Mr. Picher became president. He was director and chairman of the finance committee of the American Zinc Institute, and belonged to numerous societies and clubs. He leaves a wife and four children.

EASTERN METAL MARKET

(By wire from New York)

May 3—Copper is inactive but steady. Lead is dull and unchanged. Zinc is quiet and steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2, on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

FINANCING FOREIGN TRADE

The recent report of the National Committee on European Finance to the Chamber of Commerce of the United States has this to say regarding the need for foreign trade and the means of financing it.

"The large investor, corporate and individual, is largely unavailable because of the present tax situation. Under the existing Federal income tax, a return of 5% without tax deductions (which can be obtained from fully tax-exempt State and municipal securities of prime character) is more attractive than domestic or foreign investment subject to tax. However, modification and reduction in excess-profits tax and income tax should enable those with large incomes to invest at least a part of surplus in securities of corporations organized for internal development or to promote foreign trade. The small investor is not saving. Closely related is the almost universal speculative tendency—an insuperable obstacle to substantial sale of investment securities. Even if substantial thrift were practiced among small investors, resulting funds would not be large enough without the large investor, now substantially legislated out of the investment market. It has been difficult to make progress with investment education, as applied to foreign investment, when competition for limited domestic capital makes it impossible for American companies to secure funds they urgently need. The Treasury has invested nearly ten billion in Europe. Fiscal policies of our Government are still closely bound up with American business operations, and will have intimate bearing thereon for years. There is a widespread opinion that the Government should be a party to councils of bankers and business men when fundamental policies of foreign financing are shaped. It will be impossible to stimulate general popular support for foreign financing until governmental sanction and co-operation are afforded. Definite understanding should be arrived at regarding the policy the Government will pursue in protecting American investments in foreign countries. Continued existence of a state of war has not tended to improve confidence in conditions over-seas which must always be the basis for credit judgments. Developments have brought new political units, and new relationships. Reasonable grounds for business confidence in European conditions cannot exist until this country comes to some definite political understanding with the nations of Europe, with whom our own economic interests are inextricably linked.

"As to security in Europe for credit, distinction must be drawn between larger and more soundly established nations, such as Great Britain, France, Belgium, and Italy, and possibly Germany, and a numerous group of new small nations of unproved stability. In the latter a degree of political risk is involved beyond that reasonably undertaken by ordinary business. Greatest need for credit exists where credit risk is greatest. Very few American interests are sufficiently informed as to these smaller countries to undertake credit arrangements directly. A proper course might be to enter carefully arranged co-operative arrangements with larger political units of Europe, or private enterprise in larger European countries.

"A most important problem is how to extend further credit without added inflation at home. This country can extend further credit solely by curtailment of its own expenditures and increase in its own production."

Eastern Metal Market

New York, April 28.

The damaging effect of the railroad strike is still apparent and business in general is light in all markets. Prices have fallen in some cases.

Demand for copper is negligible, except for export, but prices are fairly firm.

There is almost no business being done in tin at any price, but quotations are steady.

In lead the situation is complex and prices vary according to sellers and position. Prompt metal, New York, is scarce. The zinc market is stagnant and prices are lower.

Antimony is quiet and unchanged.

IRON AND STEEL

The market is not merely handicapped by the forestalling of deliveries and the consequent forcing into the third quarter of much that should be shipped in the second—and all in the face of practically negligible stocks in the hands of consumers and distributors—but it is clouded by further threatening labor difficulties. To add to the unsettlement of the contemplated strike on May 1 of molders, machinists, and other crafts in some of the Middle Western cities is the continued labor agitation among the steel workers in the same sections.

The price situation is naturally strong. Conditions have not been conducive to speculative buying and world needs are still unsatisfied. And yet exceptional transactions are noted in which an independent mill has sold a large tonnage of steel bars to an agricultural implement maker for the last half at 2.90c., Pittsburgh, and has subsequently made quotations at 2.35c., the price of the Steel Corporation. Another mill has met the Steel Corporation price on shapes of 2.45 cents.

COPPER

This market is stagnant but prices are practically unchanged. Electrolytic and Lake copper are quoted more or less nominally by the large producers at 19.25c., New York, which is firmly maintained. There is an outside market where quotations are reported as low as 18.37½ to 18.50c., New York, for electrolytic, but almost no business is being done. The railroad strike has, of course, interfered with operations of refineries as well as shipments of copper on contract, and there is no reason for any one to buy. Recovery from the strike has not been sufficient to be noticed yet. Added to these conditions are strikes at certain mines and smelters which are interfering with the flow of crude copper to refineries as well as with production. Besides this there is a strike at Waterbury, Connecticut, which has tied up all the large brass plants there. It will be some days and perhaps weeks before a recovery sets in. While domestic business is dead, there continue to be almost daily sales to foreign nations, including Germany.

TIN

Conditions in this market continue unchanged. There has been and is little doing and sales have been very light indeed. The dominating factor has been the railroad strike which has effectively put the brakes on business. Tin consumers have had no occasion to enter the market and the strike has seriously affected consumption. Consumers also have troubles of their own of a different nature, and it is estimated that they have lost by the strike a month's output in their business. Conditions, particularly railroad shipping, has just commenced to improve. Yesterday and Monday there was more interest by consumers in future-shipment metal, but no business is reported to have materialized. Daily prices for spot Straits have been fairly regular around 11.5c. New York, the past week, but a drop in exchange

yesterday caused a drop in Straits tin which was quoted yesterday at 60.50c., New York. Arrivals thus far this month have been 3008 tons, with 3096 tons afloat.

LEAD

The market presents a peculiar situation and prices have a wide range. The leading interest has not lowered its quotation which remains at 9c., St. Louis, or 9.25c., New York, for early delivery. The other extreme proceeds from second hands who say they are offering metal from consumers at 8 to 8.25c., St. Louis, who bought too heavily for future delivery. This statement will persist among many who say that this is impossible and brand it as speculative operations. Contrasted to these prices are those for spot and prompt New York where the metal is very scarce, due to the railroad strikes and embargoes. For a fair business on Monday, 9 to 9.25c., New York, was realized and yesterday sales were made at 9.30c., New York. Demand in general is quiet except from needy consumers for early use. We quote the market for early delivery at 8.40c., St. Louis, or 8.75c., New York.

ZINC

The market has been erratic, prices varying not only from day to day but even at considerable spread in the same day. Quotations for prime Western fell to 7.95c., St. Louis, during the week, rose to 8.10c. on Monday, and fell back to 8c., St. Louis, yesterday, but very little business was done. London continues to make the market here, and prices there have been changeable. Foreign exchange has also had its influence as usual, the recent rapid decline of 15 to 20 points being partly responsible for the lower market here. Large producers are not interested in present levels and are well sold up to July. There is very little interest in buying beyond this date. We quote prime Western yesterday (Tuesday) at 8c., St. Louis, or 8.35c., New York, with brass special selling at 8.75c., New York, and Grade A at 9.50c.

ANTIMONY

In a quiet market the better grades are quoted at 11c., New York, duty paid, for wholesale lots. Poorer grades are held at ½ to ¾c. lower.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted at 33c. from the leading interests and at 31.50c., New York, from outside sellers, both for wholesale lots for early delivery.

ORES

Tungsten: The market is quiet and but little business has been done. The minimum price on low-grade ores is \$7 per unit. Most buyers and sellers are waiting for some action on the tariff matter.

Ferro-tungsten: is quiet at 90c. to \$1.15 per lb. of contained tungsten.

Molybdenum: In a dull market quotations are unchanged at 75c. per lb. of MoS₃ in regular standard concentrates.

Manganese: Quotations are unchanged for high-grade ore at 65 to 80c. per unit, seaboard, depending on the delivery. No transactions have been reported but demand for good-quality ore is strong.

Manganese-Iron Alloys: The ferro-manganese market is quiet but strong at \$200, delivered, for domestic alloy for last half and \$195, seaboard, for a limited quantity of British alloy for shipment from August on. For prompt and second quarter delivery \$225 to \$250 rules. There is very little business except for early delivery and here the amount available is small. The strike has seriously interfered with the shipment of alloy on contract. Spiegeleisen has sold at \$75, furnace, for early delivery.

Company Reports

LA ROSE MINES LIMITED

Report for the year ended December 31, 1919.

Property: mines in the Cobalt district include the La Rose, Violet, Princess, University, and others.

Operating Official: G. C. Bateman, general manager.

Financial Statement: gross settlements for the year, \$308,159. Adjustment for difference in stocks at beginning and end of the year make production \$356,121. Costs were \$325,919, and including miscellaneous income the profit was \$51,736.

Dividends: none during 1919.

Development: in the La Rose mine the only development work was a drift on the Powder-house vein, which disclosed a limited amount of ore of milling grade. The No. 3 shaft, which has not been re-opened since the strike, will be pumped out, as there is still a small quantity of known ore left in the workings.

At the Violet mine development was continued throughout the year, and a new level on the vein north of the shaft was opened at 250 ft. A short shoot of milling ore was found in the conglomerate on this level, but no high-grade. The ore-shoot, found the previous year on the 330-ft. level south of the shaft, was developed from a raise above the 410-ft. level, and showed profitable mill ore, with some high-grade. A limited production from these two veins was maintained.

Production: a summary of the production follows:

Mine	Dry tons	Silver, oz.	Net value
La Rose	22	30,117	\$47,589
Princess	9	6,648	8,478
Violet	23	17,494	18,351
Concentrate	661	235,059	246,198
Total	715	289,318	\$320,616

INSPIRATION CONSOLIDATED COPPER CO.

Report for the year ended December 31, 1919.

Property: mine and mill at Miami, Arizona.

Operating Official: Thomas H. Donahue, general superintendent.

Financial Statement: sales of copper, \$11,045,222; mining expenses, including development, \$3,222,261; reduction, including transportation of ore, \$3,615,690; refining and selling expenses, including transportation of metals, \$2,777,416; administration expenses and Federal taxes, \$272,523; copper on hand at beginning of year, \$2,378,099. Total, \$12,865,990. Copper on hand at end of year, \$6,118,332. Depreciation on buildings and equipment, \$348,633. Interest received, \$168,038; income from investments, \$69,660; balance, income for year, carried to foregoing balance sheet, \$4,186,628.

Dividends: \$7,091,802 during 1919; total to date, \$33,078,866.

Development: during the year a total of 21.33 miles of underground openings was driven, making a total of 149.18 miles driven in the property to the end of the year, and 6.13 miles of underground workings was destroyed in the process of mining. During the year work on the drift on the 600-ft. level through the Live Oak property, which had been discontinued in 1913, was resumed, and in the latter part of May the drift was completed. The total length of the drift from Live Oak to the main shaft is 7888 ft. During the period 248 ft. of the 600-ft. haulage level was widened so as to relieve traffic congestion. In addition to the above, 3295 ft. of haulage drifts was driven. The development work during the year was confined within the area previously prospected by churn-drilling, so that no new discoveries were made nor was any additional ore developed. The erection of the 35-ton experimental leaching

plant started in 1918 was completed and operations were begun on June 21, 1919. The results of the tests upon about 5000 tons of oxidized and mixed ores have been satisfactory, and indicate that the oxidized ores of the company can be readily and economically treated by sulphuric-acid leaching. The experiments have likewise indicated that the copper can be economically recovered by electrolytic deposition.

Production: the output of copper for the year was 78,038,306 lb., obtained from the treatment of the following ores: concentrating ore, 4,151,806 tons; main shafts, ore to smelter, 18,338 tons; Live Oak, ore to smelter, 3680 tons; Keystone, ore to smelter, 1807 tons; total, 4,175,631 tons

FRANKLIN MINING CO.

Report for the year ended December 31, 1919.

Property: mine on Portage lake and mill at Point Mills, Michigan.

Operating Official: Enoch Henderson, superintendent.

Financial Statement: mining expense, \$164,665; surface and stamp-mill expense, \$153,510, making, with miscellaneous, \$331,036. Income from copper sold and miscellaneous sources, \$192,822. Net deficit \$192,930.

Dividends: no dividends in 1919. Dividends to date, \$1,240,000.

Development: production was discontinued in May 1919, and since that time operations have consisted of taking care of the plant, keeping the mine free of water, and development work on the Pewabic amygdaloid at the bottom of No. 1 shaft. The shaft was sunk from the 37th to the 39th level and about 300 ft. of drifting done at the 39th level, which is 3900 ft. below the surface measured on the dip of the lode. The first level above the 39th on which any extensive stoping has been done is the 30th, and here the ground from 600 ft. north of the shaft to the present end of the drift at 1600 ft. north of shaft averaged good. This means that there is practically 900 ft. of unstopped ground above the present bottom opening, with the probability, judging from the 30th level, that the character of the ground will improve as drifting is continued north.

When production stopped there were better than 200,000 tons of excellent rock opened on the 18th and 19th levels at the bottom of No. 2 shaft on the Allouez conglomerate.

Production: tons of rock hoisted, 120,938; tons of rock discarded in rock-house, 11,314; tons of rock stamped, 109,565; pounds of refined copper produced, 1,062,879.

NEW IDRIA QUICKSILVER MINING CO.

Report for the year ended December 31, 1919.

Property: mine and reduction plant in San Benito county, California.

Operating Official: H. P. Baker, general manager.

Financial Statement: net proceeds of sales of quicksilver, \$560,179. Operating expense, depreciation, and depletion, \$615,686.

Dividends: \$25,000 during 1919, making total to date \$2,705,000.

Development: a new reduction plant, consisting of five rotary-kilns and condensing systems, was completed during the year, including the placing of conveyor-belts, crushers, etc., also an aerial tramway to carry away the burned ore from the furnaces. This new plant has a roasting capacity of from 400 to 500 tons of ore per day, and with the mill unit gives us the largest quicksilver reduction plant in America.

Production: the total production for the year was 7400 flasks, as compared with 10,700 for the previous year. This smaller production was due to unsettled market conditions in the early part of the year, which necessitated curtailing operations. This resulted in a loss of production of approximately three months, or 2500 flasks.

Book Reviews

Technical Writing. By T. A. Rickard. Pp. 174. Index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$1.50.

Few engineers, whether they be college-trained or self-educated, are able to express their thoughts clearly on paper. The undergraduate in a technical school is seldom compelled to devote any time to English composition, and even if he is, impatience at what seems to him to have no direct bearing on his principal studies militates against his taking interest in the subject. The self-educated man is even less likely to give any part of his limited time to something that appears to him to be unnecessary. However, after a few years, or even less time, spent in practising his profession, the young engineer is likely to discover that the ability to write well is not such a non-essential, after all. Whether he has to write a report or a technical article, he finds himself unable to express his ideas clearly and in such a way as to carry conviction. If, as a result of such an experience, he tries to improve himself, he finds that the ordinary textbook on English composition does not fit his needs. The usual result is that he abandons the task, writes as little as possible throughout his career, and writes that little poorly. The consequence is that accumulated technical knowledge, which is the sum of every man's experience, is lacking in the contribution that he might make to it, and that he himself is deprived of the friends, and possibly even the technical success, that the publication of well-written reports and articles might bring to him. The present volume has been written to fill the needs of the engineer that wishes to improve his writing abilities.

As the author states in his opening chapter, "Science is not divorced from literature and no valid reason exists why technology should be regarded as if it were legally separated from good English". The book not only shows the incorrectness of this belief, but also indicates the means whereby a better understanding between the two contracting parties may be attained. Good technical writing is shown to be not a matter of literary frills, but rather one of expressing the meaning of the writer so that the reader can grasp it without unnecessary mental effort. The rules given for accomplishing this end are necessarily many, but they are all based upon the fundamental principle, 'Remember the reader'. The titles of the chapters on Naturalness, Clearness, and Precision, respectively, are self-explanatory. In the discussion of Superlatives and Other Diluents, such as 'considerable', 'probably', and 'rather', the indiscriminate use of these words is condemned. Similar disapproval is expressed in the next chapter regarding the use of other meaningless words, a use that serves merely to weaken the sense of whatever statement is made. In the chapter on the relative pronouns, the student will be enlightened regarding the clearness obtained by the correct use of these words, which are so frequently used incorrectly in ordinary speech and writing. An important feature of the chapter on prepositions is the discussion of the use of single-word verbs in place of the preposition-verbs whose prepositions so often show a tendency to land at the end of the sentence. Hyphens as aids to clearness, particularly in technical writing, are discussed in the next chapter. The chapters on Slovenliness and Jargon appropriately follow each other, and the author has found no difficulty in collecting plenty of examples to illustrate the faults that he describes. The titles of the remaining chapters, namely, The Construction of Sentences, Composition, and Style, need no comment. Although the book is based on a series of lectures delivered before the mining students of the University of California, and most of the illustrations are naturally drawn from mining engineering, the book should be in the hands of everyone that

writes technical English, whether in book, magazine article, or trade catalogue.—A. T. P.

A Glossary of the Mining and Mineral Industry. By Albert H. Fay. Pp. 754.

Those engaged in the mining industry have long felt the need for a comprehensive glossary of the terms in use. This want has been met by Albert H. Fay, mining engineer to the U. S. Bureau of Mines, the author of Bulletin 95, 'A Glossary of the Mining and Mineral Industry', which contains about 20,000 terms and 30,000 definitions covering all phases of coal and metal mining, quarrying, metallurgical plants, coke-ovens, oil and gas wells, geology, and mineralogy. The words are arranged alphabetically in true dictionary style, there being no industrial grouping. Only one glance is necessary, therefore, to find any desired term. The type and style of composition are such as to render it easy to find the word, and read the definition. A cursory glance through the 754 pages reveals painstaking study in assembling definitions from many and varied sources, and inserting proper cross-references. The scope of the work includes all English-speaking countries, as well as much that is Latin-American. Usually the name of the State, province, or country is given, showing where the more provincial terms originated or where they are extensively used. In most cases the name of the author quoted is given in parenthesis at the end of the definition, thus making it possible to trace the term back to the publication in which it previously was defined. About 150 authors are quoted, as indicated by the list of publications cited, 100 of which publications contained glossaries relating to some phase of the mining industry. The glossary contains many words that are more or less obsolete and this feature may be considered an advantage rather than a detriment, as the older literature contains many terms that are not now current. The scientist engaged in research work is always glad to know where the older terms are properly defined. This feature of the glossary is highly commendable. Some of the terms that have figured in mining litigation, as for example, 'abandonment and forfeiture', 'apex', 'fissure', 'lode', 'vein', and scores of others, have been given special attention, a number of similar but slightly different interpretations being given and many court cases cited wherein the decisions were rendered. These court citations, in addition to definitions from other sources, add to the value of the publication from a legal standpoint. The large number of Spanish, Mexican, and South American terms makes the book doubly valuable for engineers and others engaged in the mining industry of our sister Latin-American republics.

Handbook of Ore Dressing. By A. W. Allen. Pp. 242, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

The title of the book is doubtless misleading to many. Ore dressing in this treatise refers "to those preliminary mechanical or semi-mechanical operations that precede or operate concurrently with a specialized method of extraction or recovery". Accordingly the author considers the roasting of ore and concentrate in its mechanical aspects but does not discuss amalgamation. Concentration by means of jigs, tables, and flotation machines is likewise ignored. However, having adjudged his idea of what 'ore dressing' may signify, the reader may find much of value in the book, principally a summary of the machines and equipment used for the conveying, feeding, crushing, grinding, classification, and dewatering of ore and ore pulps. Many data regarding the operations of the machines enumerated and profuse illustrations, both drawings and photographs, add to the value of the work. While it is impossible in so small a volume to go into great detail on any particular subject, a very good general survey of the more recently developed machines and methods, as well as those of an earlier day that still survive in present practice, is presented.

T. A. RICKARD, . . . Editor

IT is interesting to note that at the recent annual dinner of the Institution of Mining and Metallurgy in London, the first occasion of the kind since 1911, the chairman and president, Mr. Hugh K. Picard, stated that within five months of the declaration of war no less than 1000 out of the 2492 members joined the active forces, that is, 40%. He added regretfully that 113 members made the supreme sacrifice, not counting many others whose death was due to war service at the base.

TWO and a half million railway employees have presented a demand to the Federal Railroad Labor Board for a minimum wage of \$2500 per annum, and yet the average citizen is not perturbed, because he thinks in his ignorance that the demand does not affect him. It is a curious fact that in national, as in international, affairs the average citizen thinks his own life is delightfully detached from the troubles and complications that menace other parts of the community or other countries. In large measure the innate selfishness of man is at the bottom of most of the difficulties under which civilization staggers today; in short, civilization is only a half-baked product of human endeavor.

APPARENTLY the Mexican primary elections are almost ended and Señor Venustiano Carranza has failed to win a nominating delegation. Next will come the convention itself, which may involve further electioneering of the approved Mexican kind, with alarms and excursions, a little fighting and a lot of looting, ending in secessions of military leaders from one side to the other. At this time of writing it appears that General Alvaro Obregon and Señor Pablo Gonzales are in the lead, because they have marched at the head of their troops into Mexico City. Anything is better than the Carranza regime. General Obregon is a man of sense; we are hoping that he may succeed in winning the 'election' and be placed in a position enabling him to restore peace and order in his distracted country. We believe that he favors the assistance of American capital in developing the mineral resources of Mexico.

ACCORDING to the 'Financial Times', the Indian gold-mining companies have made a new contract with the Government, beginning May 15, whereby the Government of India has the option to purchase the whole or a portion of the output of the Kolar mines at

the London market price calculated at the current rate of rupee exchange, the gold being delivered, as heretofore, at the Bombay mint. It is part of the arrangement that in the event of the Indian government not acquiring the whole of the output, the companies shall be free to dispose of their gold in other markets. Until further notice, the Government has decided to take 75% of the gold output, so that arrangements will be made to dispose of the remaining 25% in India at the best price. Payment for the gold acquired by the Government will be made as to two-thirds in India at the ruling rate of exchange and as to one-third in sterling in London. While these arrangements do not place the Indian gold mines in as favorable a position as those in South Africa, they are much better than any previous method of realization on their output.

IN a recent editorial upon the gold bounty, we referred to Mr. Vanderlip's contention that it was undesirable to increase the gold reserve because it would permit the Federal Reserve banks to increase their note issue to the extent of a ratio of 40% gold to notes, and we proceeded to suggest that this was a weak argument because an increase, say, of 50 million dollars in our gold output would legalize an increase of only 20 millions in the note issues of the banks. This was an error, of course; the gold reserve has to be at least 40% of the note issue, not the reverse; therefore 50 millions more of gold produced would warrant a further issue of 125 millions in notes. The error does not vitiate our argument, which is that the increase of paper money, whether of 20 millions or of 125 millions, would be of small consequence to a country that has a foreign commerce amounting to 14 billion dollars per annum.

FREDERICK G. COTTRELL has been nominated by the President to the directorship of the U. S. Bureau of Mines in succession to Mr. Van. H. Manning. The nomination was sent to the Senate on May 5 and will be confirmed in due course. Dr. Cottrell was assistant to his predecessor and therefore comes into office with ample knowledge of its duties and responsibilities. He is still a young man, being only 43, so that he will be enabled to establish a personal tradition of good and useful work in his important office. He has the habit of working hard and the excellent characteristic of being able to stimulate his associates to earnest work; his

executive ability and business acumen remain to be tested, but we do not doubt he will rise to the occasion. A graduate of the University of California in 1896, he received his doctorate in philosophy from the University of Leipzig in 1902. Subsequently, while instructor and assistant professor of physical chemistry at Berkeley, he began a research into the electric precipitation of smelter fume, and made the experiments at the Selby plant that were described in our pages in 1908. Later the same device was used to prevent dust from kilns at cement plants from damaging orange groves in southern California. Since then the Cottrell 'precipitator' or 'treater' has been introduced at modern metallurgical plants all over the world, from Anaconda to Ashio. The inventor showed a rare kind of public spirit in turning over his patent-rights to a Research Corporation, formed for this purpose, in order to encourage further scientific investigation of immediate industrial importance. In 1911 Dr. Cottrell was appointed chief physical chemist to the Bureau; in 1914 he became chief chemist; in 1916, chief metallurgist, and in 1919, assistant director. He has earned his promotion to the highest office in the Bureau and we feel sure that under his direction this important scientific branch of the Government will prove itself increasingly helpful to the welfare and progress of the mining industry.

Minerals Separation Under Scrutiny

In this issue, by courtesy of the American Mining Congress, we publish a summary of the evidence given in the proceedings taken by the Federal Trade Commission against the Minerals Separation companies. The hearings are not ended, and we expect to record the future proceedings in due course. It is well that this information should be made public. We have read the verbatim reports, which are voluminous. Mr. Ballot stated that those whom he calls "infringers" are treating "from thirty to forty million tons of ore". He also said that the number of American mines using the process without license was "either 450 or 540"; he could not recall the exact figure. Only 120 are under license in the United States. The Anaconda Copper Mining Company collects the royalties payable by the companies "associated with it under the agreement" with the Minerals Separation company. These "associated" companies are the Inspiration, New Cornelia, Greene-Cananea, Calumet & Arizona, Arizona Copper, and Consolidated Coppermines. Settlements for infringement have been made by the Hecla, Tamarack & Cuuster, Hercules, and Bunker Hill & Sullivan companies. The Anaconda has recovered 100,000,000 pounds of copper by flotation; of this, 43,398,250 pounds is estimated, by Mr. Ballot, as copper that would otherwise have been lost in the tailing. Later Mr. Ballot decreased the estimated capacity of the infringers to something between 28,000,000 and 30,000,000 tons. Evidently he does not know; for the margin between 28 millions and 40 millions, the extreme figures, is so large as to suggest lack of adequate data. The Phelps Dodge Corporation has

been operating under a group agreement with the Minerals Separation people since December 31, 1917. We are amused by Dr. Seth Gregory's description of the flotation process as "so jolly simple, you know". Evidently he talked a lot of piffle before the Examiner. The serious part of his testimony was the acknowledgment that the licensees are forbidden to communicate any details of their operations to a third party. That clause, needless to say, was not imposed upon the Anaconda and Inspiration companies. The Minerals Separation people reserved the right to edit anything written by a licensee or an employee of a licensee, and, as we know, they attempted to prevent the publication of information that did not trespass upon their rights. As to Mr. T. J. Hoover's book, it appears that Mr. Ballot suggests that only "some" of his decisions in regard to the text were "respected". We have excellent reasons for knowing that Mr. Hoover did respect the agreement made by him to delete matter that Messrs. Ballantyne and Gregory deemed prejudicial to the proprietary interest of their company; yet Mr. Ballot asserts that he has not read Mr. Hoover's book, nor, of course, any later books on the subject to the commercial exploitation of which he has devoted 17 years of his life. Before the hearings are concluded, we hope to publish Mr. Hoover's testimony and that of others; meanwhile it is well to note that the first resolution passed by the Mining Convention at Seattle thanks the American Mining Congress for having instituted these proceedings against Minerals Separation.

The Day After

The Republicans of California have chosen Senator Johnson in preference to Mr. Hoover as their nominee for the Presidency. The result of the election was declared after we had gone to press last week. To us, of course, it is disappointing; it shows the strength of the political machine created by Mr. Johnson, as was shown likewise in the elections of 1916, when Mr. Charles E. Hughes was rebuffed so severely and Mr. Johnson himself stepped from the governorship to the senatorship. Mr. Hoover's friends are amateurs in politics, and that was one reason why they—and we include ourselves—did not realize the strength of the political machine that was working against him. It may be that Mr. Hoover's pronouncement of his preference for the Republican party came too late, and perhaps it was not strong enough for the purpose of the primary election. That could not be helped; it was part of the logic of events. The statement issued by Mr. Hoover the day after the Californian election was dignified and good-tempered. We think he over-estimates the importance of the League of Nations as an issue on this Coast; the farther west one goes, the feebler becomes the interest in European affairs. Senator Johnson's frothy provincialism, following upon his care not to hurt pro-German sensibilities, has helped him politically in certain quarters where votes are numerous. Mr. Hoover refers to his opponent as having saved the State from "vicious corporation control" when Governor and to his "too narrow vision on

our international necessities". That view of world affairs Mr. Johnson shares with thousands of his constituents. They would like to wash their hands of the mess in Europe; they would like to believe that the sorrows and miseries on the other side of the Atlantic are none of their business; they are glad that the continent, as well as the sea, separates them from responsibilities that they wish intensely to ignore. To them the economic solidarity of the civilized nations is a figment created by persons who are not 100% American. The fact that Mr. Hoover has shown a rare understanding of economic problems and that he has had the experience fitting him for guiding this nation during the days of economic stress so plainly visible on the horizon—all this does not interest them. The Senator voices their discontent with things as they are, he waxes indignant over the blunders of our present Chief Executive, he seems to be angry with all those accountable for making life so difficult and costly at this time. Johnson is the apostle of discontent; Hoover stands for thrift, for putting things in order, for a recognition of world realities. The one obtains a ready, because it is an unthinking, response; the other appeals most to the thoughtful man. In Berkeley, where we live, it is interesting to examine the vote by precincts and to see how 'down-town' supported Johnson just as overwhelmingly as 'up-town' voted for Hoover. In a university city like Berkeley 'up-town' does not connote wealth, it means the homes of professors, engineers, and professional men and women generally, plus a few businessmen to whom an academic neighborhood is agreeable. Unfortunately Mr. Hoover is not nearly so well known in California as is the Senator. The Berkeley 'Gazette', which is a fairly intelligent newspaper, speaks of Herbert Hoover as "that estimable civil engineer". It is as if we spoke of Mr. Johnson as "that charming admiralty lawyer". The newspapers of San Francisco were for the Senator and they took care that the public did not get to know much about Mr. Hoover; on the contrary, they fed the prejudice arising from his long residence abroad, due, as our readers know, to the exigencies of the mining profession. The 'Chronicle' said: "Mr. Hoover became known to the American people as the beneficiary of the sentiment created by the boundless generosity of that people"; that is, Mr. Hoover is trading on a sentiment for which he deserves no particular credit. Not many who read this jibe appreciated its untruth, although they may have guessed at its meanness. Mr. Hoover became known to the American people first because he organized measures of relief for American refugees passing through London, as soon as the War began in Europe. Mr. Hoover's executive ability saved the day, not the "boundless generosity" of anybody. Next Mr. Hoover set to work to organize relief for the Belgians; again it was his executive ability and the assistance he obtained from a number of American mining engineers, in the first place, that made the Commission for Relief in Belgium synonymous with efficiency and effectiveness. Again the 'Chronicle's' "boundless generosity" is irrelevant. Mr. Hoover risked his own fortune at the start, until he obtained recognition and assistance from the British government. The Ameri-

can government did not participate directly, financially or otherwise, until after the United States entered the War. At the end of 1916, out of the \$227,500,000 devoted to Belgian relief, the people of the United States had subscribed only \$10,000,000, and the profit made in this country on the \$125,000,000 of supplies bought by the Commission amounted to \$30,000,000. Canada gave 18 cents per capita, New Zealand \$2.34, and Tasmania \$6.25. The American people averaged 8 cents apiece. These facts were stated in a letter issued by a group of representative mining engineers in New York in December 1916. Later the American government gave large funds for relief in Europe, but by that time Mr. Hoover was as well known as President Wilson. The 'Chronicle's' "boundless generosity", it is evident, has no rhetorical value; yet such statements depreciating Mr. Hoover's work, and making him merely the figure-head of our national response to the world tragedy, are readily accepted as authoritative, particularly when the suggestion ministers to the self-complacency of the unfortunate readers of an ignorant newspaper. Thus it has come about that one of the greatest of living Americans, in many respects the most notable figure to emerge from the stress of the Great War, is even denied the characteristic of being thoroughly American. It seems fortunate that Mr. Hoover was elected president of the American Institute of Mining and Metallurgical Engineers before the presidential campaign and before Messrs. De Young and Hearst had proved him much less American than themselves.

What the Miners Think

At the recent International (that is, Canadian and American) Mining Convention at Seattle a number of resolutions were passed, unanimously. It is interesting to note the subjects with which they were concerned. First was one endorsing the American Mining Congress for "taking the lead in maintaining proceedings against Minerals Separation, Ltd., its subsidiaries and agents, charging them with stifling and suppressing competition, monopolistic and oppressive practices and violations of the Clayton and Federal Trade Commission Acts". To the American Mining Congress were tendered "thanks for its action" and an "offer of unqualified endorsement". As our own opinions on the subject are well known, we venture to add that we had no representative in the Committee on Resolutions and had nothing whatever to do with instigating any of the resolutions passed at Seattle. The second resolution was a tribute to the public service rendered by Mr. James F. Callbreath, the secretary of the American Mining Congress. To him was tendered "this expression of our sincere appreciation of his ceaseless efforts in our behalf", and, as a concrete expression of thanks, it was recommended that "immediate steps should be taken to secure from North-West mining interests a measure of financial and moral support more commensurate with Mr. Callbreath's efforts". This resolution met with cordial, as well as unanimous, support. Next, the Convention demanded "immediate legislation

fostering the production of war minerals, in order that the United States and Canada may be industrially independent both in times of peace and in times of war". This resolution reflected the sentiment evoked by discussions on the production of magnesite, chrome, and tungsten in the North-West. The fourth resolution dealt with excess-profit and corporation taxes; it described them as "cumbersome to collect and vicious in effect, bearing inequitably and constituting a premium upon inflated capitalization, a penalty upon conservative financing, and an incentive to the withdrawal of funds from all investments but those that are tax-free"; therefore the Convention, "Canadian delegates not voting", called for "the speedy repeal of these acts and the substitution of taxation measures that will be equitable in their operation and permit of the distribution of corporation earnings upon a fair basis". The fifth, "Canadian delegates not voting" again, animadverted against the delay in awarding assistance to claimants under the War Minerals Relief Act, and condemned the "constructions and limitations now placed upon this law" by which "large numbers of worthy claimants are denied the relief intended by the law". Therefore the Convention urged "the immediate passage of legislation now before Congress to provide a more liberal administration of the War Minerals Relief Act, so that the intentions of that Act may be carried out with justice and forthwith". The next subject was the protection of American citizens in foreign countries. Reference was made to the fact that "on repeated invitations of the Mexican government prior to 1910, and since, American mining engineers, operators, and employees in large numbers have joined in the industrial development of Mexico, pursuing their professions in lawful and orderly manner, with full regard for the rights of the Mexican people, and for their obligation as American citizens to their own government", and "whereas in recent years of revolution and disorder, many American citizens in peaceful pursuit of their professions and in the guardianship of properties entrusted to their care have suffered great financial losses, personal indignities, injuries, and death", therefore the American delegates to the Convention unite in protesting "to the Department of State of the United States against further disregard of conditions in Mexico that make it unsafe" for Americans to attend to their legitimate business in Mexico. Further it was resolved "that the Government of the United States take such steps as will ensure that every American residing or having property in any foreign country shall receive the full protection of the United States government, both for himself and for his property". This resolution, we suggest, is significant, timely, and entirely commendable. The seventh resolution asserted "that the United States and Canada should be jealously reserved as the home of all who believe in our institutions and only for those who subscribe to our laws and appreciate the freedom guaranteed by our Constitutions", and that therefore "all within these borders, either foreign or of native birth, who deliberately attempt to foment industrial or social unrest should be treated as

enemies and speedily and severely be dealt with as such". The resolution then proceeds to "demand enactment of additional laws to sweep away all legal obstruction to the prompt suppression of insidious anarchy that threatens the institutions we love". This is well meant, but too sweeping. We would make a distinction between the foreigner and the native-born, allowing the latter a wider latitude in his criticism of his own Government or system of government. Besides, the resolution seems to label all strikes and other forms of protest as anarchistic, whereas most of them are not. We think this resolution ill considered and badly expressed, for it displays an illiberal spirit under the cloak of loyalty. The eighth resolution thanked Messrs. Emmet D. Boyle of Nevada, John Clausen of Seattle, E. G. Crawford of Portland, T. A. Rickard of San Francisco, and Frank A. Vanderlip of New York for their "enlightening and inspiring addresses". The ninth suggested that R. G. Dun and Bradstreets "should place mining properties and business on an equality with all other businesses, and therefore these companies are hereby requested to give ratings of mining business in the same way and for the same purpose as now done with respect to other business". We approve of this, because, among other reasons, it would give employment to several score worthy mining engineers, without whose aid no such ratings of mining ventures would be practicable. The tenth resolution recommended that as "technical questions relating to mining industry are fully covered in the technical press" and by engineering societies, therefore it would be well in future to devote the annual sessions of this Convention to questions "of commercial and legislative nature". This sets a good example to other similar conventions, especially to those of the American Mining Congress. The eleventh resolution advised "the preparation and publication of elementary works upon practical geology and mineralogy in simple language devoid of technicalities" with a view to benefiting "the prospector in the intelligent conduct of his work". This is something much to be desired, but not easily consummated, for the man that can write on scientific matters in plain English is rare indeed; the ability to do so is the supreme test of scientific knowledge and literary skill. The next subject was the gold problem. A resolution asserted that "there is no economic formula which should expect the production of gold at a loss to the producer thereof for use in the arts and industries", therefore the Convention "endorses the measure now introduced by Congressman McFadden, chairman of the House Committee of Commerce and Banking in the House of Representatives of the Congress of the United States". A resolution advocating the remonetization of silver was referred to a special committee, this being a tactful method of shelving a subject that might arouse a controversy prejudicial to the effort now being made to assist gold mining. It will be noted that the resolutions cover a wide range in economics. Undoubtedly they express the sense of a thoroughly representative convention of miners, engineers, and operators; and for that reason they are well worthy of record.

DISCUSSION

Filing of Mine Reports

The Editor:

Sir—Recent communications to your paper have suggested the timeliness of making a record of a matter which I have written about before and which has been favorably discussed, but not seriously approved of as yet.

I refer to the plan to have mining companies file, with the State Mining Bureau, accurate and complete maps concerning the underground development and conditions, so that these records may be available in the future in connection with the development of adjacent properties, or the re-opening of old mines. The record of this work is of public interest, as every engineer knows who has had occasion to examine old properties, or go into districts in which there had been earlier operations. Countless cases prove how advantageous this information would be, not only as a saver of time and experience, but as a criterion by which the value of the old property under new conditions can be easily ascertained.

Objections have been raised that this information is private property and might work to the injury of individual operators. This could easily be overcome by permitting the reports to be sealed for a definite period, only to be opened by order of court or termination of the sealed period.

This idea has been embodied in some recent legislature in Ontario and some of the States in the East have adopted the idea as a local regulation.

KIRBY THOMAS.

New York, March 28.

A Protest

The Editor:

Sir—My attention was first called to your editorial 'To Young Engineers' in your issue of April 17, 1920, by an indignant protest from a loyal Californian now residing in Arizona. The resentful feelings of a group of mining students were voiced in my office yesterday morning. I think it most unfortunate that you should, both by direct statement and implication, so scathingly condemn students of such an institution as the University of California, as unmanly, undemocratic, and un-American because of a time-honored custom of the upper classmen to wear 'cords'. I have heard you make the remark on many occasions that certain newspapers published in San Francisco "have a whole lot of taste—all bad". Imitation is the sincerest flattery! Even though corduroy grates on your aesthetic sense, is there any need or justification for the statement that they are 'dirty'? And what if they are, it's clean honest dirt!

The University of California has certain traditions, beloved and supported by all loyal alumni, alumnae, and students: the freshman hat, the sophomore cap, the junior 'cords', and the senior Stetson; the rallies, the pilgrimage, the serpentine, and the yells. Why brand them as provincial or denounce them ridiculous when they have survived generation after generation! Let us respect the short jacket and silk hat of Eton, the long blue coats and yellow stockings of the Blue coat School, the crimson skull cap of Harvard, and the 'cords' of California, one is as provincial as the other maybe, but they are dear to the hearts of the student body. Then Sir, you say the wearing of distinctive dress is un-American, this hurts; you are treading on dangerous ground here. To emphasize your point, you, like the great Disraeli, in the exuberance of your own verbosity, maintain a more or less consistent line of argument to malign an opponent and glorify yourself. Permit me to coin a word and characterize your denouncement as being typically 'Rickardesque'. I quote from your editorial "it becomes neither a democrat nor an American to be boorish in speech".

The Corporation and the Individual

The Editor:

Sir—Senator Hiram Johnson of California, candidate for President, has attained much of his following by his supposed opposition to corporations. Early in his career, he assailed the Southern Pacific in whirlwind style, and people applauded him. Those who knew nothing about the Southern Pacific liked to hear him attack that company. People the country over will listen to a forceful speaker who condemns the corporations. There is a strong undercurrent of resentment against corporations in general. Though J. Parke Channing and others have explained clearly that the country needs them and that, if all the wealth were divided equally, the individual would get only a small amount, still people dislike a corporation even while accepting its money as wages. What is the reason for this antagonism?

The answer lies in the manner in which corporations treat the individual: Individuals in their contact with one another give and take. A corporation gives rebuffs but never takes them; like the old-style schoolmaster, it is always right. If you disagree with it, you are wrong. It doesn't argue, it tells you. You either do things in the

corporation's way or you cease to have relations with it. Like the once-famous Kaiser, it "won't stand any nonsense". Mr. Statler, who has built up a great hotel business, tells his employees that the customer is always right. The corporation imbues its executives with the idea that the corporation is always right.

Now, a British writer said recently that what men want is power; they want to feel themselves as being in the centre of the stage. To become the cynosure of as many eyes as possible, men will struggle far into the night, will organize labor strikes, or even become ministers of the gospel. When the very human wish to express one's self and criticize things runs against the usual attitude of the corporation not to accept criticism, there come grievance and dissatisfaction. People dislike the sacrosanct 'infallibility' of corporations, which they know to be managed by men as likely to be stupid and to commit blunders as anyone else. Men holding positions of responsibility in a corporation will do, in the name of their company, things which they would hesitate to do as individuals. Normal fellows, fortified in a position with a 'big corporation', will forget their real personality and take on the corporational condescension and infallibility. Like some of the boyish officers during the War, they think that the assumption of an external thing like a uniform or a roll-top desk changes them into supermen whose word must be law.

When a corporation offers a man a position, it always regards itself as conferring a remarkable favor. Even though the salary is small and the work is drudgery, it never unbends from this top-lofty attitude. Frequently it prefers not to suggest a definite figure for a salary, for fear, apparently, that it will offer too much, but asks the fortunate one what is the least salary that he will take. This 'least salary' is then frowned upon by a succession of higher officials, who convey to the prospective employee their belief that he will not be worth such an extraordinary amount for many months, but that the philanthropic company will graciously throw the money away in the hope that later his services will prove to be a good bargain. That is, the company is willing to lose \$125 per month for a while, on the chance that afterward it will get a \$500-per-month man at \$200 per month. Business is business, of course, and corporations must make a profit somehow. If a profit can't be made at the expense of the men earning wages, because of the unrest and the unions, there is the opportunity of getting young college men to work cheaply by explaining to them the wonderful experience in which they may revel when harnessed down to the great corporation which "owns all these buildings" and whose "name is a byword in the field". Selah!

Lest it be thought that a critic who sees much hypocrisy and bluff in the way in which a corporation deals with the individual, can see no good in any corporation, it may be said that many officials remain human in spite of all efforts of the bureaucrats to inoculate them. An increasing number, perhaps, are submitting to the cant of the industrial hierarchy only to a minimum degree. The

pious 'bunk' about 'experience' and 'the necessity of low salaries so that young men will not get the swelled head' is fooling fewer people each year.

P. B. McDONALD.

New York, April 22.

The Future of Chromite in the United States

The Editor:

Sir—In your last issue there was an article on this subject by Samuel H. Dolbear, which nettled me considerably. It was stated by Mr. Dolbear that we had discovered no chromite mines in the United States which were comparable with those of New Caledonia and Rhodesia, and yet by some strange process of deduction Mr. Dolbear states that the production in the United States was more than 82,000 tons, which figure exceeds very largely the normal importation of chrome ore, which Mr. Dolbear's figures show to be less than 50,000 tons. It would seem, therefore, in spite of the fact that no mines comparable with those in New Caledonia and Rhodesia were found, nevertheless we produced more ore in the United States than was normally imported, and imports of chrome ore have come from a great many countries, including New Caledonia, Rhodesia, Cuba, Brazil, and Nicaragua.

Mr. Dolbear also states that the deposits in New Caledonia and Rhodesia are larger and purer than those in the United States. I do not know whether Mr. Dolbear has examined the Rhodesia and New Caledonia deposits or not, but I do know that there are several large high-grade deposits in California that Mr. Dolbear has not examined, including some of the properties which have been operated by me. I have talked with engineers who have been in New Caledonia, Cuba, and Brazil. I have correspondence in my office with one of the largest Rhodesian firms dealing in chrome ore, and I have also correspondence in my office from New Caledonia. From all the information I could gather from the sources mentioned, the chrome deposits in these countries are very similar to our own, and in no instance have I any definite information showing that the imported ore is any higher in quality than some of our California and Oregon ores.

As a matter of pride in our domestic production, it is astounding to read such statements which belittle our ores with such apparent lack of foundation. Mr. Dolbear's attitude is apparently against the tariff measure, notwithstanding his statement that he is a protectionist; but as one of the largest producers of chrome ore in the past, I cannot let this statement go unchallenged that our deposits in the United States are insignificant in quality and quantity as compared with the foreign ones, when to my own knowledge chrome ore has been shipped from California of very high quality, and correspondence from Rhodesia which I have, shows they have difficulty in securing high-grade chromite in that section.

C. S. MALTBY.

San Francisco, May 3.

The Bunker Hill Enterprise—IX

Inner History of the Company: Its Personnel and Its Finance

By T. A. RICKARD

In the fall of 1885 the locators of the mine commissioned James F. Wardner to obtain working capital for the erection of a mill, and he, as previously related, went to Helena, Montana, where he enlisted the interest of A. M. Holter and S. T. Hauser. The former established the A. M. Holter Hardware Co. in 1866, and it is still going. He and Hauser were active mine operators at that time and later developed the Helena & Frisco mine, near Wallace. Mr. Holter, now 89, is still living at Helena. Mr. Hauser was president of the First National Bank of Helena. They joined with A. M. Esler and W. E. Cox, both of Helena, together with D. C. Corbin of Spokane, in forming a syndicate, which accepted Wardner's proposal to concentrate 50,000 tons of ore at \$5 per ton, the concentrator to have a capacity of 100 tons per day, and to be built forthwith. This group organized the Helena Concentrating Co., with Hauser as president and Cox as secretary.* Esler was sent to the mine. At that period few men in the West knew much about designing a lead concentrator; Esler gave the job to Alfred Bradford, a flour-mill builder, and he was compelled soon to confess his metallurgical shortcomings. Thereupon Esler sent to Helena for R. K. Neill, then a millwright, now honorably prominent as the man who has recently opened up the silver bonanza of the Bush, or Premier, mine in the Salmon River district, British Columbia. Mr. Neill told me recently how he rode up Milo gulch on horseback, with his kit of tools on a packhorse. The going was bad, because there was no road, and the fallen logs across the creek made it difficult for the horses. The surrounding hills, and the gulch as well, had been swept by a forest-fire during the preceding summer.

Ground was broken for the mill on April 10, 1886; and the plant started to work on July 20. Wardner and his associates had bound themselves to have the mill at work on August 1, and they just succeeded in fulfilling this part of their contract, despite the unfavorable conditions, for everything had to be hauled from the Mission landing over a bad wagon-road. The cost of treatment was about 50 cents per ton, so the margin of operating profit was handsome. The 'joker' in the deal was that the owners of the mine were not protected by any definition of 'ore', therefore Wardner and his associates could treat material of any grade, provided the returns sufficed to pay them the \$5 per ton. The locators and their friends received no money until the smelter (at Wickes, Montana) and railroad had been paid their respective charges. Thus the

owners of the mine had the small end of the stick, and they fared badly. This forced them to give the mill people an option on the property. This option called for \$200,000; but at that time the development of the mine did not justify such a price, so they did nothing. However, they obtained a sixteenth interest in the Sullivan mine. Later, the owners gave Wardner an option, and early in 1886 he found a purchaser in Simeon G. Reed, at the rumored price of \$650,000. Mr. Reed would not buy the property until the contract with the mill people was cancelled, so, after much 'dickering', they sold out for \$100,000, for which Reed got the mill, the milling contract, and the sixteenth interest in the Sullivan mine. The sellers took options on some adjoining claims and did some prospecting, but nothing came of it. Corbin started at once to build a railroad from the Mission landing to Wardner and thereby contributed greatly not only to the development of the Bunker Hill but of the entire Coeur d'Alene region.

W. L. Lee, now living at Helena, Montana, was foreman of the mine at the time of Wardner's option. From Mr. Lee I gather that the mine was badly worked; it was being 'gouged' in the effort to maintain a large production of concentrate. Wardner had but little notion of real mining or of the true condition of the property. He ordered Lee to knock down and ship a mass of clean galena held in reserve in the Sullivan, but it was explained to him that this rich ore, and a similar 'bunch' in the Bunker Hill, was needed for 'sweetening' the output from the lean places. Although the mineral looked 'pure', it could be seen, on examination under a magnifying glass, that the cubes of galena were encased in a film of quartz, which made a difference of 8 to 10 in lead percentage between the concentrate and the lump ore. Mr. Lee says:

"The walls of the Sullivan were regular and well defined, but the Bunker Hill was broken up and more inclined to be lumpy. The walls of both mines dipped south, and the orebodies dipped west. On the Sullivan there was a mass of quartz about 40 ft. wide and over 200 ft. in length that formed the top of the main shoot or chimney of lead ore. The quartz contained no values except native crystallized silver, in wires about $\frac{1}{4}$ inch long, very bright, and pretty to look at. This silver occurred only in the seams and crevices."

When Reed visited the mine, for the purpose of inspecting it, although he also knew nothing of mining, he was astonished at the showing made by the 21 ft. of galena in the Sullivan. He exclaimed, "Well, that's better

*For these details I am indebted to Mr. Cox, who is now living at Seattle.

than I ever expected to see". This face of galena had been left intact for the purpose of helping a sale. Reed departed next day, with Wardner, and ten days later Lee received a telegram from the latter ordering him to measure the ore in the mine and on the dump, and to get his report to Spokane within three days. Shortly afterward Reed informed Lee by letter that he had bought the mine and wanted him to remain as foreman. Then came Joshua E. Clayton, with instructions also to report on the mine. After a week or more, the "Professor" asked Lee what his estimate had been, and expressed agreement as to the tonnage. When Wardner arrived, he told Lee that he had not shown his estimate to Reed, because it was so much below the figures he himself had stated to Reed. Thereupon Lee resigned. He was asked by Reed to come to Spokane, where he told Reed the whole story, which did not seem to perturb the new owner of the mine. Reed wanted Lee to return, but he refused. By way of summary, Mr. Lee writes: "Prof. Clayton and I talked freely about the property, and he agreed with me that there was not \$150,000 in sight at that time in the property that Mr. Reed had paid \$650,000 cash for, and I firmly believe that the 21 ft. of lead ore sold the Sullivan & Bunker Hill property. Professor Clayton got \$500 for his report and I got \$20 for mine, and we both got the same results, but, best of all, the mine was there—the biggest silver-lead property in the world."

The Bunker Hill & Sullivan Mining & Concentrating Company was incorporated under the laws of Oregon, at Portland, on July 29, 1887, by S. G. Reed, his secretary (Martin Winch), and N. S. Kellogg. The capitalization was \$3,000,000 in 300,000 shares of \$10 each. Of these 250,000 were issued. Information concerning the amount of money paid for the various mining claims acquired by the company at the start is not now available, because the old records were kept in the office at Kellogg and were destroyed when the building was dynamited in 1899; other records of the company were burnt in the San Francisco earthquake-fire of 1906. Out of the 250,000 shares issued, 249,998 went to S. G. Reed, and one share apiece went to Martin Winch and N. S. Kellogg. On October 3, however, Kellogg received 33,872 shares from Reed's allotment. He sold out on March 31, 1890. Sullivan received 1694 shares from Reed on November 7, 1887, but he disposed of them all before December 18, 1891. O'Rourke received 6774 shares on April 27, 1888, and sold them prior to January 11, 1894. Thus all the discoverers ceased to be shareholders within seven years.

"Sin" Reed, as he was generally known, was a good specimen of the business man of the frontier days. He was a native of Massachusetts and came to San Francisco, by way of Panama, in 1852, when he was 22 years old. He was a clerk and then a partner in the firm of W. S. Ladd & Co. In 1858 he became active in the development of the steamship business and founded the Oregon Steam Navigation Company in 1860. His connection with this enterprise, as director and vice-president, lasted until the transfer of the property to the Villard Syndicate for \$5,000,000 in 1879. In the same year he participated with A. Onderdonk and D. O. Mills

in a contract for building the first section of the Canadian Pacific Railway, from Port Moody to Kamloops, in British Columbia. In 1882 he organized the Oregon Iron & Steel Co. and erected a plant to make pig-iron and cast-iron pipe, in which respect this plant was a pioneer on the Pacific Coast. He was regarded as a man of sagacious and enterprising character, with the courage to face and overcome difficulties. He owned the Abington building, the largest office-building in the city of Portland, and he is said to have mortgaged this property in order to raise the money needed to purchase the Bunker Hill and Sullivan mines. He sold his shares in the Bunker Hill company because bad health prevented him from devoting his personal attention to the management. Having made the sale, he went to Europe for a holiday. In 1904 he gave \$3,000,000 to found the Reed Institute, at Portland. This college is a monument to his intelligence and generosity. He died at Pasadena, California, on November 7, 1905.

Shortly after purchasing the mine, Reed asked W. B. Bourn, of San Francisco, to recommend a superintendent, and Mr. Bourn recommended Victor Clement, formerly of Los Angeles, a graduate from the Santa Clara college, and at that time in charge of the Empire mine at Grass Valley, California. He was appointed manager on August 1, 1887, with a salary of \$500 per month and expenses. In July 1891 this salary was increased to \$10,000 per annum. Clement proceeded to Wardner and soon advised Reed that money would be needed to build a tramway, as well as a concentrator of better design and larger capacity than the mill that had been erected at the mouth of the Small Hopes tunnel, in Milo gulch.

The new mill was built at Kellogg in 1891. It was connected with the mines by a Bleichert tramway, erected in the same year by the Trenton Iron Works and reconstructed by them in 1892. This tramway had a horizontal length of 10,000 ft. and cost, in all, \$92,635. It proved a troublesome affair. The nominal capacity was 400 tons per day. At the beginning the cost of carrying ore over the tramway was greater than if it had been done by horse and wagon. Owing to defects in design and erection there were frequent accidents, which not only interrupted the delivery of ore to the mill and consequently increased the operating cost, but the dropping of buckets upon the town of Wardner caused endless difficulties. One span, 1400 ft. long, passed over the town. Buckets dropped from the line, so that persons in their homes and horses in the street were killed. A new type of button was put on the moving rope, the brake station in the town was cut out, and one long span substituted, thereby diminishing the liability to accident; at the same time the number of buckets was increased and the tramway was worked over-time, so that its average capacity was increased to 520 tons per day before its use was superseded by an adit.

The records show that although 213,108 tons of ore was mined up to May 31, 1892, for which the smelter made returns of \$1,923,083, yielding an operating profit of \$899,601, the company was unable to accumulate sufficient money to provide the plant and equipment neces-

sary for its expanding operations. In September 1890 Reed made a deal with John Hays Hammond whereby the latter, in consideration of a commission of 2500 shares of the company's stock, agreed to find \$300,000 of working capital. On October 2 Mr. Hammond obtained \$150,000 from D. O. Mills, as a loan at 10% on 50,000 shares, with an option to buy them at \$3 per share. This option Mr. Mills exercised on June 17, 1891. Mr. Hammond sold another block of 50,000 shares at \$3 to a Chicago syndicate headed by James H. Houghteling, of Peabody, Houghteling & Co. This money was needed to make the improvements recommended in a report by H. H. Webb, including the Bleichert tramway and the new mill. Early in January of the following year (1891) the secretary's report showed a deficit of \$130,000 and stated that the new concentrating plant at Kellogg would not start work until April, at which time a profit of \$60,000 per month was anticipated. A loan of \$60,000 was made by the First National Bank of Portland, this debt being reduced to \$35,000 by July. A little later, in consequence of the company's purchase of a number of additional mining claims, its indebtedness to the Portland bank increased to a point where it became embarrassing. Thereupon, on September 18, 1891, W. H. Crocker of San Francisco loaned the company \$110,000 at 1% per month, and a week later he became a director. Mr. Crocker's bank became the depository of the company's funds; he has been a member of the executive committee and treasurer of the company ever since, in which capacity he has loyally served it through its every financial necessity. On May 31, 1892, the Bunker Hill company's balance-sheet showed assets of \$3,483,277, with liabilities, in the form of money due, amounting to \$167,000. In September of that year Mr. Mills again stepped into the breach by loaning \$50,000 at 10% to apply on the indebtedness. At about the same time General N. H. Harris, uncle-in-law of Mr. Hammond, lent the company \$20,000 at 10%, for the purchase of the 'Lackawanna' claim. In May 1893 the net assets had risen to \$3,657,554 and the cash liabilities had decreased to \$63,000.

Many transfers of stock were made during these years. Mr. Hammond obtained his first holding as a commission, as we have seen; prior to September 21, 1892, he owned 32,962 shares. He now owns 15,001, and Mrs. Hammond holds 3499, plus the 500 which she inherited from the estate of her uncle, General Harris. Mr. Hammond obtained 1220 from Reed, 9796 from Kellogg, 625 from Mills, 15,858 from Crocker, 500 from Forbes-Leith, 500 from C. L. Hutchinson, and 5000 in the Chicago syndicate sale. Victor Clement acquired 36,301 shares, which he held to the time of his death. He obtained 12,979 from Reed, 4075 from Hammond, 16,051 from Kellogg, 625 from Mills, and 2571 from Mrs. W. H. Crocker.

The shares acquired by Hammond and Clement from Kellogg formed part of Kellogg's original holding of 33,873 shares, which Clement contracted to purchase on March 31, 1890, and two-fifths of which he assigned to George Crocker. Under the terms of this purchase the shares would have cost about \$2.21 apiece. A sum equal to 74 cents per share was paid to Kellogg at the time, the balance being payable two years later, with interest at 5%. One cannot but note that Kellogg got 5% on his deferred money, whereas money at the time commanded as much as 1% per month. During the interval, before the Kellogg deal was consummated, Clement was free to vote Kellogg's stock and received the dividends paid upon it, but he was under obligation to pay any assessments that might be levied. The remainder of Kellogg's stock, 8026 shares, was not taken up by George Crocker, but by another member of the Crocker family. In January 1894 Mills acquired 5349 of O'Rourke's shares. Cyrus H. McCormick, of the American Harvester Company, became a shareholder in February 1891; he still holds 19,500 shares. Simeon Reed sold his last shares on June 2, 1893. They are worth now \$50 apiece.

The accompanying tabulation records the names of the successive presidents, managers, and assistant-managers, with the time of their service. On July 2, 1891, Reed was succeeded as president by Hammond, who was placed on the salary list at \$500 per month on July 30, 1892, or

LISTS OF PRESIDENTS, MANAGERS, AND ASSISTANT-MANAGERS

According to Official Records

			Presidents	Managers	Assistant-Managers
July	29, 1887, to	July 2, 1891	S. G. Reed
August	1, 1887, "	March 20, 1893	V. M. Clement
October	1, 1890, "	March 20, 1893	F. W. Bradley
July	2, 1891, "	June 15, 1893	J. H. Hammond
March	20, 1893, "	June 1, 1901	F. W. Bradley
June	15, 1893, "	June 17, 1897	N. H. Harris
May	15, 1897, "	June 1, 1901	A. Burch
June	17, 1897, "	date	F. W. Bradley
June	1, 1901, "	June 16, 1904*	A. Burch
June	23, 1903,†	June 16, 1904	S. A. Easton
June	16, 1904, "	date	S. A. Easton

*Burch ceased to be Manager (Easton taking his place as such) on January 1, 1903, but, according to the records, Burch did not relinquish title until June 16, 1904.

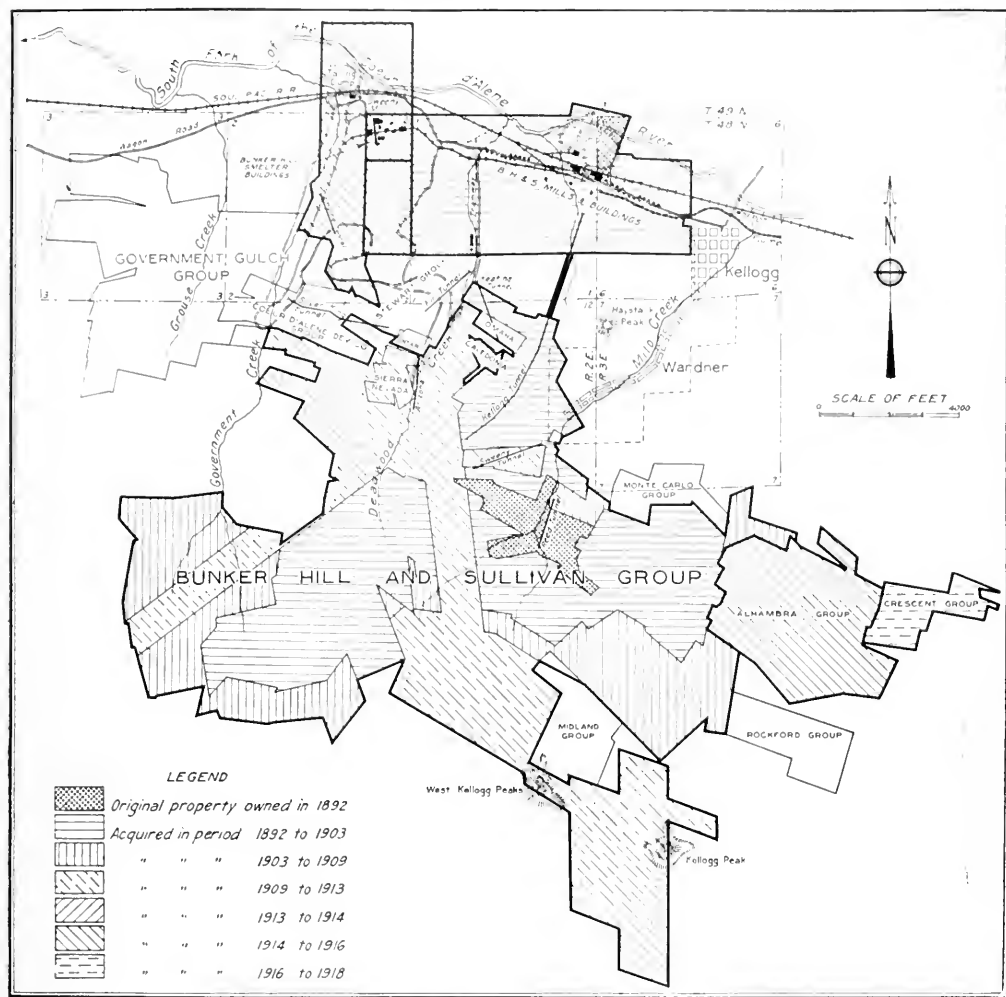

†According to the records, Easton was appointed Assistant-Manager on June 23, 1903, but began his connection as such in July 1902.

F. Burbidge served as Acting Manager from July 1897 to June 1, 1901.

thirteen months after his election to the presidency of the company. He left the United States for South Africa in 1893, and was succeeded by General Harris on June 15 of that year. The General retired four years later in favor of Frederick W. Bradley, who has continued in office ever since. Mr. Bradley had been appointed as-

able of American mine operators. In 1897 I met Clement at Kalgoorlie, in Western Australia. He was a most capable engineer and a man of sterling character. He died at Saltillo, in Mexico, on April 26, 1903.

H. H. Webb was assistant to Clement in 1889. C. R. Corning was consulting engineer to the company for

MAP OF THE BUNKER HILL PROPERTY

sistant-manager in 1890 and manager in 1893, so that he was manager and president concurrently for four years. He has been an officer of the company for 30 years. The first manager, Victor Clement, left the mine to go to South Africa with Mr. Hammond in 1893, after having been manager for nearly six years. He became manager of the Simmer & Jack mine at Johannesburg and returned to the United States in 1896, becoming associated with the late Capt. J. R. De Lamar, one of the most not-

three years from 1893. Albert Burch was appointed assistant-manager in 1897 and was promoted to manager in 1901. After that he served as consulting engineer until June 1906. Stanly A. Easton followed Mr. Burch as assistant-manager in July 1902 and became manager on January 1, 1903. He has been manager continuously since then, a period of 17 years.

We have seen that in 1892 the Bunker Hill enterprise was not looking cheerful; the operating profit was about

\$250,000 per year, it is true, but this revenue was insufficient to provide for the necessary improvements, as well as pay for the additional mining claims that had to be purchased. In the fall of 1892 Hammond wrote to Clement suggesting that they had better get out and take advantage of the boom in South African mining, because he anticipated that the earnings of the Bunker Hill would all be absorbed by the changes to be made in the existing plant and in the purchase of additional equipment. So he sent Ernest Wiltsee to London as an advance agent and shortly thereafter accepted a retainer from Barney Barnato. When Hammond and Clement left, the Bunker Hill was heavily in debt and it had less ore in reserve than at any time since. Soon after their departure the silver panic of 1893 prevented the shipment of ore to the smelter. Those were dark days; but they were the darkness before the dawn. In June 1894 the company owed only \$9571. In that year the first dividend was paid. Between 1894 and 1900 the net assets of the company rose to \$4,436,993 and it paid \$750,000 in dividends, besides having a cash reserve of \$266,283.

The Kellogg tunnel was started in 1897 and reached the vein in 1901, but it did not cut the main Bunker Hill ore-shoot until 1904. The cost of driving this adit had to be met out of current earnings, while the right to extend it was contested bitterly by a neighboring company, which eventually forced the Bunker Hill company to divert the course of the adit around certain property lines. The completion of this work not only afforded cheaper facilities for moving ore from the mine to the mill but permitted a large increase in the tonnage mined and milled, thereby diminishing the cost per ton; indeed, it is not too much to say that if the adit had not been driven at the time it was and if it had not cut a big swell of ore where it intersected the main Bunker Hill ore-shoot, there would have supervened then as close a shave for the continuity of profitable operations as the enterprise experienced when the mine, plant, and offices were dynamited in 1899. Of these happenings, and of the strike in 1892, I shall speak in a separate article.

The story of general economies is told by the following figures, giving the total working cost:

	Per ton
January 1902.....	\$2.57
" 1903.....	2.61
" 1904.....	2.00
" 1905.....	1.68
June 1905.....	1.49

However, the reduction in working cost was not the sole factor in establishing the prosperity of the mine, as the accompanying graph, recording the economic history of the enterprise, will show. In 1888 the cost was \$3.95 and in 1889 it was \$4.23 per ton. We have seen how it fell to \$1.40 in June 1905; after that it rose steadily, thus:

Year ending May	1906.....	\$1.746
" " "	1907.....	1.977

NOTE: Use figures below the lines for tons of lead only.

* Excess of Dividends over operating profit due to disbursement of receipts from sale of Tacoma Smelter Company Stock.

GRAPHIC RECORD OF ECONOMIC HISTORY

"	"	"	1908.....	2.181
"	"	"	1909.....	2.210
"	"	"	1910.....	2.090
"	"	"	1911.....	2.036
"	"	December	1912.....	2.250
"	"	"	1913.....	2.770
"	"	"	1914.....	2.438
"	"	"	1915.....	2.488
"	"	"	1916.....	3.033
"	"	"	1917.....	3.312
"	"	"	1918.....	3.702

The average for 32 years has been \$2.546 per ton. It will be noted that the War brought its burdens, for during the period 1915-1918 the cost averaged \$3.07, or 72

cents more per ton than in the preceding four years. The service of the Kellogg tunnel was the chief cause, as we have seen, in reducing the operating cost up to 1905; when this adit was completed the mill was supplied for a time from one or more large stopes directly at the end of the tunnel; since then the cost has increased because the ore has had to be collected from many different and scattered stopes, and then hoisted or lowered to the adit, according to its source, before being trammed to the mill. This factor has been of persistently increasing importance, and the effect of it has been, as the records show, to augment the cost from \$1.746 per ton in 1906 to \$2.438 in 1914, an increase of 69 cents per ton. Since then higher wages, shorter hours, greater cost of machinery and supplies, and of rail transportation, have been unfavorable factors, culminating in 1918, in which year the average operating cost per ton was the highest incurred since 1893.

In 1902, after Hammond and Clement had returned from South Africa, they endeavored to promote a sale of the Bunker Hill to the Guggenheims at \$10 per share. They themselves were willing to take \$8 for their stock, and after Clement's death in 1903 Mrs. Clement, knowing his views as to the value of the stock, gave an option to Mr. Bradley on her 36,301 shares at \$8 per share. Mr. Bradley gave the principal shareholders a chance to buy this holding, but neither he nor his friends took any action in the matter. Up to that time the total dividends had only amounted to \$4.20 per share. Shortly afterward the March orebody was opened up and the sale of the Tacoma smelter in 1905 yielded an extra dividend of \$5 per share, just prior to the payment of which, Daniel Guggenheim and brothers bought Mrs. Clement's stock at \$25 per share, making for her a total of \$907,525. Let us call it a million to make it romantic, for, it did indeed punctuate a romantic story. Flora Smith was a girl of 16 when she and her sister arrived in the gold-mining camp of Murray in 1885. Adam Aulbach tells me that Miss Smith was the belle of that frontier community, and those who have known either Mrs. Clement or Mrs. Cloman will not hesitate to believe it. Later she went to Miss Lake's school in San Francisco for two years. In 1891 she married Victor Clement at Portland and they then returned to Wardner on the eve of the big strike in the Cœur d'Alene. She shared that trying experience with her husband and she also shared his interesting experiences in South Africa, Utah, and Mexico. Four years after his death, she married Capt. Sidney Cloman of the U. S. Army, who in 1906 was military attaché at the American legation in London. There she and her gallant husband made many friends. Capt. Cloman had retired from service when the United States declared war against Germany, but he volunteered immediately and served in France with such distinction as to win the Distinguished Service Medal and the Croix de Guerre. They are now living at Burlingame, near San Francisco. Mr. Guggenheim bought Mrs. Cloman's shares, to their mutual benefit. Since 1902 dividends totaling \$74 per share have been paid on the original 300,000 shares, and, in addition, the enterprise out of its

own earnings has paid for the Kellogg adit, several mills, and other plants, including a \$3,000,000 smelter. On December 31, 1919, the mine had 5,116,938 tons of ore blocked out, and the company had \$2,383,933 in hand in cash and bonds.

(To be continued)

Peruvian Copper & Smelting Co.

Considerable interest has been aroused in Peru by the recent construction and development work of the Peruvian Copper & Smelting Co., which has a \$10,000,000 authorized capital. The stock has not been offered to the public or listed on any exchange. The money thus far has been provided by syndicate financing.

Last year the company acquired extensive copper properties at Yauricocha and Felicidad, 50 miles from Pachacayo station on the Central Railroad of Peru; also several square miles of coal-lands in the heart of the Jatunhuasi district, 30 miles from Pachacayo. This is the most important coal-fields in Peru and the engineers report that on the company's property is a deposit of 10,000,000 tons of good bituminous coal and that numerous samples taken along continuous veins for a distance of over three miles all produce excellent coke for smelting operations.

At Yauricocha, the company's copper mines have been partly developed by two main shafts each over 200 ft. deep, numerous drifts and tunnels revealing a large body of ore averaging 12% copper and considerable silver. The company's undeveloped property at Felicidad, seven miles from Yauricocha, is overlapped by the largest gossan outcrop thus far discovered in Peru, similar in character to that found at Cerro de Paseo and according to engineers familiar with both properties, likely to show a copper ore deposit fully as extensive.

The Peruvian Copper & Smelting Co. is now engaged in timbering double-compartment shafts at Yauricocha, extending its underground workings to connect its principal shafts preliminary to production, and erecting blast-furnaces and reverberatory smelters and a hydro-electric plant, most of which equipment has already been delivered. Also a contract has been let for the construction of a battery of coke-ovens at the company's Jatunhuasi coal mines and the building of a road, employing several hundred native laborers, is being rapidly pushed from the Central Railroad of Peru at Pachacayo to Jatunhuasi coal-fields and Yauricocha smelter and copper mines.

This road will give a down-grade haul of 30 miles from the Jatunhuasi coal mines and coke-ovens at 15,000 ft. elevation to Pachacayo station at 11,630 ft. and a down-grade haul of 16 miles from the company's coal mines and coke-ovens to its smelters at 13,225 ft. elevation near Yauricocha copper mines. This comparatively short haul of coal and coke to smelter and the location of the latter in the immediate vicinity of the copper mines, thus minimizing ore transportation, gives the company in connection with exceptionally high-grade 12% copper ore, an opportunity for low cost production.

Proceedings Against Minerals Separation Before the Federal Trade Commission

The hearings in the Federal Trade Commission's proceeding against Minerals Separation, Ltd., Minerals Separation North American Corporation, Beer, Sondheimer & Co., and other respondents, whom the Commission has charged with suppressing competition by an oppressive system of license agreements with mining companies throughout the United States, commenced in New York on April 7 and continued to April 16, when they were adjourned.

John Ballot, the first witness, testified that he is a British subject residing in the United States, and has been connected with the various Minerals Separation companies from the beginning. Mr. Ballot is chairman of the three British Minerals Separation companies and is president of the Minerals Separation North American Corporation.

Minerals Separation, Ltd., the parent company, was organized in London in 1903 for the purpose of developing processes of ore concentration. This was two years prior to the discovery of the flotation process in the laboratories of Sulman, Picard, and Ballot. In 1910, it was decided to exploit the patents obtained for this process in the United States and accordingly Minerals Separation American Syndicate, Ltd., was organized in London with a capital of £52,500. This corporation acquired the American rights to flotation patents, and worked in conjunction with Beer, Sondheimer & Co., who became its American agents in 1911.

Beer, Sondheimer & Co. was a German firm, with its principal office at Frankfort, Germany, and one of the Sondheimers was a director in the American syndicate. The German firm was also one of the three stockholders of the American syndicate, Minerals Separation, Ltd., and Lazard Brothers of London being the other two. Benno Elkan and Otto Frohnknecht were the local representatives of Beer, Sondheimer & Co. in New York.

In 1913, the need for additional capital was felt in connection with the American venture, and accordingly Minerals Separation American Syndicate (1913) Ltd. was organized with a capital of £250,000, taking over all the business of the first American syndicate. At the outbreak of war, Beer, Sondheimer & Co. of Frankfort owned 32,165 shares in this (1913) syndicate. Its principal stockholders, in September 1916, were Beer, Sondheimer & Co. of Frankfort, Elkan and Frohnknecht of Beer, Sondheimer & Co.'s New York office, Lazard Brothers of London, and the parent company. By that time, the Public Trustee of Great Britain had intervened and seized the stock interest of Beer, Sondheimer & Co. of Frankfort.

At the outbreak of the War, Minerals Separation American Syndicate (1913) Ltd. found itself a British company represented in the United States by Beer, Sond-

heimer & Co., an enemy German firm. Eminent English counsel, Sir Frederick Smith, now Lord Chancellor of England, advised that continuance of any agency relations with the New York representatives of Beer, Sondheimer & Co. was very dubious, but the problem was taken up with British authorities in connection with the Trading with the Enemy Act, and after the agency agreement with Beer, Sondheimer & Co. had been changed in several respects in deference to British regulations, exclusive agency relations with Elkan and Frohnknecht, the New York representatives of Beer, Sondheimer & Co., were continued until the latter part of 1916. Later, in 1916, 17,500 shares of (1913) Syndicate stock were issued to Elkan and Frohnknecht in commutation of their exclusive agency commissions past and future.

In 1916, for the purpose of obtaining the advantages of an American status, it was deemed advisable to have the American business conducted by an American corporation, and to this end Minerals Separation North American Corporation was incorporated on December 7, 1916, under the laws of Maryland. The new corporation rented part of Beer, Sondheimer & Co.'s offices at 61 Broadway, New York, and acquired all the American rights and took over all the Minerals Separation business heretofore transacted by Beer, Sondheimer & Co. and the American syndicates. Part of the arrangement was that Elkan and Frohnknecht should acquire 35,000 voting-trust certificates in the new company, and become its general agents, which voting-trust certificates and all dividends thereon should be held for their benefit by Guaranty Trust Company of New York, and delivered over to them only after the close of the War. Elkan and Frohnknecht, meanwhile, had taken steps to become American citizens. This arrangement regarding Elkan and Frohnknecht's voting-trust certificates was upset, however, when the Alien Property Custodian, in Washington, after prolonged investigation, seized these certificates on the ground that Elkan and Frohnknecht had acquired them actually in behalf of Beer, Sondheimer & Co. of Frankfort. The Alien Property Custodian also seized 65,230 more voting-trust certificates, representing the interest of Beer, Sondheimer & Co. of Frankfort through the latter's ownership of 32,615 shares in the (1913) American syndicate, so that over 100,000 voting-trust certificates have now been taken over by the Alien Property Custodian as having been German-controlled.

The schedule of royalty rates put out by Minerals Separation North American Corporation was introduced in evidence. It showed four methods for computing royalties: percentage, unitage, tonnage, and a flat rate. Great stress was laid by Mr. Ballot upon the fact that the licensee was permitted to choose any of these methods that might suit him, but Dr. Gregory later testified that

as a matter of fact all these royalty rates worked out practically to the same result. Out of every dollar's worth saved, Dr. Gregory testified, "We ought to get something in the neighborhood of, say, ten cents to satisfy our own end, and we framed our royalty to suit that". "All those various schedules really amount to that."

Mr. Ballot estimated that there were 120 licensees under the Minerals Separation patents treating about 28,000,000 tons of ore annually, and about 500 infringers treating about 40,000,000 tons of ore annually. During the War, according to Mr. Ballot, Minerals Separation refrained from prosecuting infringers in order to permit the greatest possible production of metal for America and her Allies. Now, however, the Minerals Separation policy is to settle with infringers upon payment of double the usual royalties during the period of infringement and then to issue a license at regular rates. "If I am an infringer, and want to atone for my past misdeeds, and agree to pay double the amount of this schedule which may be collected, I am shriven for my past misdeeds, and have the right to take a license." "And if I don't want to take a license, you (Minerals Separation North American Corporation) will shrive me for my past deeds, and let me go my way, whether I take a license or not," is the way counsel for Minerals Separation North American Corporation expressed it.

Although Minerals Separation North American Corporation, in its formal answer to the Federal Trade Commission's complaint, declared that only two exceptions had ever been made to its standard form of license agreement, Mr. Ballot admitted that at least 11 large companies were working under license agreements which differed from the standard form. Inquiry by the Federal Trade Commission's counsel also elicited the information that there were three other special license agreements and that a rebate of one-half the prescribed royalty had been made to another large company.

The financial condition of Minerals Separation North American Corporation proved to be delicate ground, and inquiry concerning it by the Federal Trade Commission's counsel aroused strenuous opposition on the part of the Corporation's counsel. Mr. Ballot was asked to tell the corporation's gross income, but after a heated argument was directed by his counsel not to answer, and accordingly he refused to do so. He likewise refused to state the book-value of the corporation's stock or to answer any other question touching on income, dividends, surplus, or profits, although demanded to answer by the examiner of the Federal Trade Commission conducting the investigation.

Dr. Gregory testified that he is a British subject, born in Persia, and residing in the United States, and has been connected with the Minerals Separation companies since the start. He is resident managing director of the British companies, and is now vice-president of the North American Corporation. Dr. Gregory was anxious to explain the provisions of the Minerals Separation license agreement, which he declared had been unjustly criti-

cized. "Our contract," Dr. Gregory testified, "is designed to prevent, if I may use the word, crooks from over-reaching themselves, but with the honest man our contract has absolutely no fears." To the objection that their contract never terminates, Dr. Gregory replied that it "terminates upon their ceasing to use the flotation process, and it commences again when they start to use it." Referring to the clause of the Minerals Separation contract relating to the use of apparatus not covered by Minerals Separation patents, Dr. Gregory stated that "as a protection to ourselves we put in this clause", "that when you are going to use our process you must use our apparatus". The clause regarding the acquisition of inventions made by Minerals Separation licensees was inserted, Dr. Gregory testified, because "we wanted to make ourselves a sort of exchange whereby all our clients would get the benefit of the inventions mutually, without any extra expense".

Dr. Gregory told of Minerals Separation's methods of getting evidence against Mr. Hyde and the Butte & Superior company. "They had got their door locked. They had it fortified in every way so as to make it impossible for us to get in. So we were compelled to trespass—absolute robbery. Our chief engineer went right into the place by force", "Mr. Nutter, and he took some of the stuff and put it into a bottle, and they nearly knocked his head off, and they followed him", "and in the meantime he had posted the bottle under registered cover, and so on, to our patent lawyers". "You have to set a thief to catch a thief, don't you know." "We may have occasion to employ men who will use their ingenuity and skill to get into places and find out what people are doing." "If I were to go and to ask them to let me in, they might ask me to walk out, or what not; so we have to use all the modern methods that everybody uses, as detectives." Referring to these methods, Mr. Ballot testified: "It was an awkward thing to do and an unpleasant thing to do, but it was a necessity. That necessity required a man to handle it carefully." Accordingly a mining engineer who had formerly acted as agent for Beer, Sondheimer & Co. was asked to "get the necessary information", and, according to Mr. Ballot, upon his recommendation a "man was engaged at a regular salary and proceeded to Butte and there entered the service of the Butte & Superior company, and got the information, reported the information, which was sent to the New York office—I think most of the correspondence was afterwards addressed to myself". "The men who got the information were never put on the stand." Numerous letters between these spies and this former agent of Beer, Sondheimer & Co., and Mr. Ballot and other officers of Minerals Separation North American Corporation referring to the employment of these spies and their compensation by Minerals Separation and their reports of their observations at the plants of the Butte & Superior company, the Miami Copper company, and elsewhere, including one letter, dated January 10, 1918, upon the letterhead of the Salt Lake City representative of Beer, Sondheimer & Co., Inc., addressed to Mr.

Ballot and informing him that the writer had "secured by devious and most unethical methods a sample of X Cake which I am sending by registered mail to Mr. Higgins today", were put into the record by the Federal Trade Commission's counsel.

Dr. Gregory stated that Minerals Separation did not guarantee the validity of its patents, and referred to its "dangerous patent position". Under clause No. 6 of its license agreement, Minerals Separation, according to Dr. Gregory, reserves the right to edit publications by its licensees on the subject of flotation. "As long as it does not in any way hurt us," "we are not concerned about it." "Your opponents never hesitate to attack you from any quarter that it is possible to attack from. I mean, if you take out a patent, they immediately bind us to anything that is in that patent, by saying, 'Why you yourselves called this a froth flotation. How can you say that that is not the same as the other?'" "They have tried very hard to fix us to certain things in order to invalidate our patents by quotations from statements of our employees." "Therefore, we consider it wise, especially when our patent position is in such a dangerous position, not to allow half-cooked and half-baked statements to come out, the responsibility of which ultimately rests upon us. That was one of the reasons why we came to the conclusion that, while it may seem that the outer world does not get half-baked ideas, we did not think it right that they should get to know things under conditions which they would use against us. It is self-protection." "I would say that it was an absolute dereliction of duty on my part if I allowed an employee of ours to go and ruin the prospect of a company just because he wanted to air his views, which might be nothing or which might be something; and that is the reason that we introduced that in that contract." "We have had requests, which we have more often refused, when we have discovered that it is not right, or where we have been able to satisfy ourselves that it would be innocuous, we have allowed it; but it has done us harm, nevertheless, although we thought that it was innocuous." "We have to take our chances, to satisfy the vanity of our licensees. It does not mean money to them so much as it means the publication of their works, etc."

"This process," said Dr. Gregory, describing flotation, "is so jolly simple, you have only to take the stuff and put it in the box—I don't care what kind of a box you like to put it in, you know; you can put it into any sort of a box, and you can put a paddle into it, and shake it up, and it will come out; it is finished. It is so jolly simple, as I said before, that everybody thinks they can work this."

Neither Dr. Gregory nor Mr. Ballot would admit that there were any authoritative books on the subject of flotation. Dr. Gregory stated that he had not read Mr. Rickard's book, and Mr. Ballot testified: "Minerals Separation permitted T. J. Hoover to write a book, or compile a book. T. J. Hoover was general manager of Minerals Separation for a period of years. The manuscript of that book was submitted to Minerals Separation di-

rectors for approval. There were certain excisions made from it, because it was considered impolitic at that time, as against the company's commercial interest, to publish certain things, as the company was engaged in very active litigation. Some of these decisions he respected, and I think some of the matter was printed even without permission, without being finally passed." Mr. Ballot declared, however, that he had not read Mr. Hoover's book.

Mr. Frohnknecht testified that he came to the United States from Germany in 1906 with Mr. Elkan to take charge of the American branch of Beer, Sondheimer & Co., with which firm he had been connected in Frankfurt for several years previous. Mr. Frohnknecht was a German subject, but took steps to become an American citizen in August 1914, immediately after the European war broke out. Speaking of the business transacted by Elkan and Frohnknecht as the New York branch of Beer, Sondheimer & Co., of Frankfurt, ex-Secretary of War Lindley M. Garrison, counsel for Frohnknecht, stated that unquestionably it was entirely the business of the German firm.

Elkan and Frohnknecht handled the Minerals Separation agency for Beer, Sondheimer & Co. until October 5, 1914, when they took it over for themselves, receiving 17,500 shares of the (1913) American syndicate stock in lieu of commissions. Upon the organization of the North American corporation, each became entitled to 17,500 shares of stock, and the North American corporation took over the entire management of Minerals Separation affairs in the United States.

In 1915, Beer, Sondheimer & Company, Inc., was organized, taking over all Elkan and Frohnknecht's business except Minerals Separation matters, and Elkan became president and Frohnknecht vice-president of the new company. The offices of Beer, Sondheimer & Company, Inc., adjoined those of Minerals Separation North American Corporation at 61 Broadway, New York. Although Minerals Separation North American Corporation rent a part of their space from Beer, Sondheimer & Company, Inc., and the president and vice-president of Beer, Sondheimer & Company, Inc., were general agents of the latter and each owned a large block of Minerals Separation North American Corporation voting-trust certificates, until the Alien Property Custodian, in Washington, intervened and took over these certificates on the ground that they really belonged to Beer, Sondheimer & Co. of Frankfurt, Germany, it was emphasized by the Minerals Separation representatives of Beer, Sondheimer & Company, Inc., and Minerals Separation North American Corporation have no real working arrangement or understanding at the present time.

The hearings have been adjourned for a few weeks to permit Federal Trade Commission's counsel to study the evidence introduced, and to examine further the books and records of respondents.

During 1918, 400 tons of strontium was produced in the United States, compared with 4035 in 1917.

Operation of the Case Oil-Fired Assay-Furnace

By F. BORZYNSKI

The introduction and extensive use of the Case oil-fired assay-furnace, brought forth a large number of complaints. Certain assaying establishments, schools, and individuals using the furnace, stated that it was unsatisfactory; the chief objections being the difficulty in cupelling and the great difference of temperature between the front and the rear parts of the furnace. Some users of the Case furnaces even went so far as to scrap them, one of these being a prominent Western mining-school.

Most of the complaining assayers stated that the only way they could cupel, was to open the door of the furnace. This is a serious objection, because on opening the door

nace is to be started. When the motor attains full speed, a small piece of waste previously soaked in gasoline is lighted and introduced into the furnace. The waste is held near one side of the front baffle with a pair of cupel-tongs and makes a satisfactory kindling. The oil and the air are then turned on gradually until about six inches of flame is visible above the front damper. The furnace smokes for a minute or two, but it soon stops, and the flame appears first above the front and then above the rear dampers.

In a single-muffle furnace, it is generally necessary to open the air-valve as wide as possible. When only a part

the front part of the muffle cools to such an extent that the buttons freeze. If an attempt is made to keep up the temperature of the furnace by increasing the flame, a reducing instead of oxidizing atmosphere is produced in the muffle and the cupellation stops entirely. This condition is intensified if there are any cracks in the muffle, for then the reducing fume enters the interior. The reducing gases not only stop the cupellation, but they are also absorbed by the cupels and the molten metal, and when the amount of fuel is reduced so as to re-start cupellation a violent spitting is caused by the released gas.

I have used several types of this furnace in actual assay-work and found them satisfactory in every way. It is hoped that the following description of the method of operation as practised by me will interest users of the Case furnace who have experienced difficulties in getting the best results.

Before starting the furnace, the draft-regulator and both dampers are opened wide. The air-valve is set at 'off' and the blower started. It is necessary to have the air-valve closed, otherwise the strong blast of air entering the furnace will extinguish the light with which the fur-

of the equipment of the multiple-type furnace is used, there is an abundance of air; only enough of it for perfect combustion is admitted into the furnace and the draft-regulator is kept closed at all times. In order to produce the necessary reducing-flame for making fusions and to heat the front end of the muffle, the rear damper is nearly or entirely closed. The front damper is kept open always. When the rear damper is closed, it is found that a considerable part of the flame from the furnace is entering the muffle through the vent at the rear. By admitting a sufficient amount of oil into the furnace, a flame is caused to play outside the muffle, making the temperature in the front part nearly if not quite the same as that in the rear.

The cupels are placed in the muffle immediately after the fusion charges are withdrawn. The condition of the furnace is not changed in any way until a minute or two before the lead buttons are placed in the cupels, when the rear damper is opened wide. As soon as the buttons are placed, the front door of the muffle is closed, keeping only the slot open. When all the buttons are melted and ready to cupel, the air and oil are cut down to half the amount

necessary during fusion and the front regulator closed if still open.

Starting with a cold furnace, the first fusion is obtained in about 45 minutes and each succeeding fusion in a little less than 30 minutes. A half-hour is more than sufficient to cupel a muffle of 20-gm. buttons. The door of the furnace is shut at all times except when placing or withdrawing the cupels or the charges from the muffle, and in this way the chilling of the front part of the muffle is avoided.

When setting up the furnace, it is well to place a water-trap somewhere in the oil-pipe, preferably a short distance in front of the stop-valve. The arrangement shown in the enclosed sketch gives satisfactory results. All oils contain water and if no provision is made to remove it, much annoyance will be experienced in starting the furnace. This water, if allowed to remain in the pipe, will extinguish the fire soon after the furnace is started and fill the assay-room with smoke and the furnace with a mixture of oil and water.

Lead Deposits in South Africa

Lead ores are found in South Africa, as in many other parts of the world, in the limestone and dolomite of the older geological formations. Small pockets of galena, in some cases argentiferous, are frequently found in the dolomite series of the Transvaal. In the Pretoria series true veins are found carrying galena either alone or associated with gold, silver, copper, and cobalt. In the Pretoria, Rustenburg, and Marico districts are many vein-deposits of lead ores associated with copper, the best known being the Transvaal Silver mine in the Pretoria district, where argentiferous galena is associated with iron pyrite, copper pyrite, copper carbonate, and tetrahedrite, in a gangue of siderite. The vein is associated with a diabase dike. At the Willows mine is a very similar deposit but without the lead ore. At Edendale, four miles north of Hatherley a vein has been worked in which galena occurs in conjunction with zinc-blende and the usual oxidized ores of lead and zinc. The gangue material is mainly quartz and calcite. At Leeuwkloof the galena is found in the form of a large shoot in the dolomite underlying the shales of the Pretoria series, and at the contact with the shales. The shoot strikes north-west and dips to the south-west. The galena is of good quality, the 700 tons so far extracted averaging 73 to 75% lead. The value in silver is constant, always being between 2 and 4 oz. per ton. Associated with this lode is a large body of iron pyrite about 100 ft. thick. At Rhenosterhoek the deposit is also in dolomite, almost at its junction with the Pretoria series. It is similar in character to all the other small galena deposits in this district, the ore usually being discovered through small outcrops of galena showing on the surface, and in almost all cases decreasing in value at depth, usually being exhausted at a depth of about 50 ft. The Rhenosterhoek deposit was discovered in this manner some 35 years ago, and a small amount of galena was at that time taken out by means of open-out workings. The

mine is now being worked through an adit driven into the base of the hill on which the deposit occurs, at a level of 75 ft. below the original outcrop, at which depth solid dolomite is found, and the vertical extension of the galena deposit, in its original form, appears to be reached. The ore is now extracted principally by overhand stoping, and the deposit increases in value as the work approaches the surface.

LODE-TIN MINING is not popular in Australia, although it has provided the most profitable tin mines. The Mt. Bischoff and the Vulean properties with many smaller ones in the Irvinebank district in Queensland, may be cited in this regard. At the same time lode-tin mining shows as large a proportion of failures as gold or any other branch of mining—perhaps a larger proportion. There are several reasons for this. Sometimes it is due to the situation of the property, where it may be difficult to secure and retain suitable labor, or a permanent water supply. Frequently it is due to bad management, or an unsuitable treatment-plant. The complex nature of the ore carrying the tin, or the erratic nature of the deposit, may be contributing factors. Often a proposition that ought to pay handsomely, if worked on a fairly large scale, fails because only a small and unsuitable plant is provided; an attempt is made in that case to work only the richer portions. However, with the gradual elimination of the alluvial deposits as producers, the increasing demand for tin, and the consequent probable favorable price to producers, lode-tin mining is likely to receive greater attention in the future, especially as more economical methods become available and as many of the complex ores can now be satisfactorily treated. This is satisfactory as far as Australia is concerned, for there are a large number of deposits of lode tin in the States. In New South Wales alone, according to Carne's 'Tin Mining Industry', considerably over 200 are mentioned as having had more or less work done on them; in addition there are a large number of others, some of a promising character. Probably there are, at least, as many in Queensland, and there are a number in the Northern territory. In Western Australia there are a few that have had work done on them. Even in South Australia, which produces no tin at present, there are tin-bearing formations.

CADMIUM produced in the United States during 1919 amounted to 99,939 lb., compared with 127,164 lb. in 1918 and 207,408 lb. in 1917, the maximum output in the history of the industry. The production of cadmium sulphide was 31,197 lb., compared with 51,702 lb. in 1918. The combined value of metallic cadmium and cadmium sulphide in 1919 was about \$160,000, compared with \$258,518 in 1918 and \$376,036 in 1917. Though prices of cadmium were somewhat lower in 1919 than in the three years immediately preceding, the industry closed the year in better condition than in 1918, for the reason that the consumption practically reached the level established in 1916-17, and this with the decreased production operated to reduce stocks.

Mining in Narrow Stopes

By E. A. COLBURN, Jr.

The mining of narrow veins in hard or tough country-rock presents problems which differ materially from those faced in the extraction of ore from large deposits. Veins of this character must be composed of high-grade ore, and it must be saved in as clean a condition as possible in order to carry the extra cost per ton entailed by the mining of small ore-shoots. It is difficult to produce a high-grade ore on account of the relatively large amounts of waste that must be broken to provide space for working, and it is equally difficult to break the ground when it is mined in such narrow stopes as are necessary to recover the ore clean.

To mine such orebodies at a profit requires extra supervision of the ordinary miner, or else a class of miners more highly trained in this particular work than it is usually possible to obtain under company operation, and as a result the lessee has largely taken over the mining of narrow or pinched ore-shoots even in the larger mines. It may be proper to say here that this is especially true since the start of the world war and the era of high prices both for labor and supplies. The shortage of labor has been so great at times that in certain districts it has been impossible to secure men in any other manner, and even the larger stopes have been leased or the work done under contracts allowing the miner favorable terms.

The fact that the efficiency of men under company pay has dropped materially since the War has resulted in the abandonment of many stopes that were formerly on a paying basis under company operation. Many of these stopes are leased to miners who either do their own work, or who have the opportunity for closer supervision over the men that they employ than possible where operated on company account. The efficiency of the leasing system is due largely to the willingness of the miner to do more and better work for himself than for a company.

The advantages of the leasing system, where applied intelligently on small ore-shoots, are generally acknowledged, and are reflected not only in current production but in greater prospecting activity. Each lessee is continually looking and prospecting for further ore upon which he may work when his present lease expires, thus forming a crew of intelligent prospectors that the company could by no means afford to duplicate.

A few practical suggestions drawn from long experience with the leasing system when operated in connection with narrow veins should be of value to others operating under like conditions.

The old system of stripping the hard streaks and gouging the soft ones is in use to a limited extent where machine-drills are not available, and where it is imperative to secure a high-grade product on account of heavy freight and treatment charges; but this has long been

discarded in districts where the ore is milled locally and where tonnage is a decisive factor. Under this stripping system one or two rows of holes are drilled in one or the other wall, according to their relative hardness; after the holes are blasted the ore is removed from the wall by means of gads, or by 'pops' drilled at intervals back of the streak. When the veins are composed of soft ma-

FIG. 1

terial, the ore is gouged ahead as far as possible; and later as much of the waste as is necessary to make room is drilled and blasted. This method is slow and wasteful, as a certain amount of ore is lost in the filling. The cost per ton is high and the tonnage low.

In case a vein is being mined under such conditions it

FIG. 2

is possible to drill directly in the ore; one row of holes is drilled in the vein and another row far enough away to produce a stope of convenient width. This arrangement allows a hole in the vein to be loaded heavily and blasted before its opposite wall-hole, thus pulverizing the ore and forming a cut to which the wall-hole can be slabbled. By this alternation much less fine waste is produced, as less powder is used in the wall-holes. Stope-rounds drilled in this way throw most of the ore into the fine or screening. The system is in general use at Cripple Creek and in other gold districts where the veins favor such procedure. The coarse waste is easily sorted out, either underground

or on surface, as conditions may demand, and any coarse ore that does not pulverize can also be saved in this way. This system has the advantage of leaving a good wall on one side of the stope; however, in a vein that is given to jumping about, this wall should be watched closely for stringers or feeders, which might carry off the ore.

Where veins that cannot be drilled are being mined, this system can be modified by straddling the streak with two rows of holes, drilling the ore-holes as near as possible to the ore and eventually bottoming or finishing them in the ore. This allows the drilling of all holes in the country-rock and the inspection of both walls of the vein. If a wall must be carried on one side of the stope, all the holes should be drilled on one side of the vein, with one row near and bottoming in the streak, to be blasted as described above.

In case it is not possible to drill directly in the vein, to bottom the holes in or near it, on account of its vuggy character or hardness, the two rows of holes are placed on opposite sides of the vein, as close together as possible so that they will still break to the required size. In soft ground the holes are often staggered as shown in Fig. 1, which represents the back of a stope as seen from below. When the rock is homogeneous and free from slips, each hole is loaded with the same amount of powder; as this is rarely the case, however, the holes are loaded according to the judgment of the miner, due advantage being taken of all slips, or joints. Holes are shot alternately; that is, the first hole in one row is spit, and the first in the other row, and so on till the round is completed. In hard rock the staggered round is not practicable, as it places too much burden on each hole and causes them to 'gum' or 'boot-leg'. Ordinarily in hard ground the number of holes would be doubled and placed opposite each other on each side of the streak, the round being shot in the manner just described.

When it is desired to carry the stope as narrow as 24 to 30 in., and an effort is made to break a 3 to 4-ft. cut, it often happens that the bottoms of the holes break out, leaving a bar of unbroken ground at the collar. In some districts this is called 'tunneling'; it is illustrated in Fig. 2, a section along the plane of a vein. 'Tunneling' often occurs in stopes passing through alternate layers of hard and soft ground whenever the holes collar on the hard rock and bottom in the soft. As the ribs must be removed to allow work to proceed, the labor and materials used are virtually wasted. Breaks of this kind must be avoided. The best remedy is the drilling of more and shorter holes, and the next best is the putting of more ground on the bottoms of the holes. The former is open to the objection that a machine-man can accomplish more drilling in a given length of time when drilling long holes than when drilling short ones. This loss, however, is inevitable and will amount to much less than that caused by 'tunneling'. Putting more burden on the bottoms of the holes is satisfactory in soft ground but is poor practice in hard stopes, as the extra powder necessary to cause a clean break will often shake up the wall-rock and cause danger; it will also produce a greater pro-

portion of fine waste, and thus lower the grade of the ore.

Whenever a narrow vein is being mined for mill-ore, and no attempt is made to sort out a high-grade product for shipment, the system of drilling one row of holes in or near the vein is best, because the ore is almost entirely segregated in the fine and can be separated from the waste by means of grizzlies or screens. A grizzly with 3-in. openings will usually produce a sufficiently high-grade product, and the oversize or waste can be sorted, if it contains enough ore to pay the expense of the extra labor. It is apparent, however, that the best method of mining any particular sort of narrow orebody is dependent upon the conditions surrounding the vein and upon the grade of the product most desired.

Where air-feed hammer-drills are used it is common practice to drill all holes in a narrow stope from one plank-set in a convenient position, usually near the foot-wall. When holes are drilled in this manner it is difficult to estimate where they will 'finish', as the holes in the different rows are farther apart at the bottoms than at the collars, like a hand with the fingers stretched apart. All holes should be drilled as nearly parallel as possible to the vein and the other holes in the round, thus avoiding wedge-shaped blocks between holes and producing a more even excavation after blasting.

A NEW TYPE of asbestos was discovered in central Transvaal, South Africa, about the year 1907, according to Oliver Bowles in a recent bulletin of the U. S. Bureau of Mines. The name 'amosite' was given to the fibre in 1918, from the initial letters of the Asbestos Mines of South Africa, the company chiefly interested in its production. Amosite is a monoclinic ferrous amphibole, with or without soda, and containing variable amounts of aluminum, magnesium, and calcium. It thus most nearly resembles crocidolite or blue asbestos. The deposit occurs along the Elifants river in the Lydenburg district, the fibre-bearing rocks occurring in an area 60 miles long and with a maximum width of 6 miles. Commercial production began about 1916, and while no figures are available for the production of this particular variety, the increase in production for the Transvaal of 55 tons in 1915 to 3192 tons in 1917 is to be attributed chiefly to the recent active development of the amosite deposits. The material occurs as interbedded cross-fibre veins in banded siliceous ferruginous slates. The productive veins vary from 2 to 7 inches in thickness. The most remarkable feature of the fibre is its great length. A maximum fibre length of 11 inches has been noted, while the bulk of the supply from the most important mine averages about 6 inches in length. The fibre is said to be strong, flexible, and therefore of spinning quality, though, on account of the unusual fibre length, certain modifications are necessary in spinning machinery. The chief production is from two mines, the Egnep, producing about four-fifths, and the Amosa, one-fifth of the total. As a source of supply for America the deposits are handicapped by excessive transportation costs.

Engineering Activities of Universities and Government Bureaus

*A sub-committee of the Commonwealth Club of California was organized at the suggestion of S. H. Dolbear, chairman of the Mineral Resources section of the club, to investigate the scope and character of the activities of various State and Federal institutions, universities, and members of university faculties in the field of engineering, with particular reference to the mineral industry. The rather imposing list of Federal and State institutions engaged in scientific and engineering activities of one sort or another in California and various specific instances of efforts to extend the field of activity of certain of these organizations furnishes ground for the belief that there is a definite trend toward socialization in the field of applied science. The purpose of the Committee was to ascertain the facts and if possible formulate some judgment as to whether existing conditions and tendencies are desirable or otherwise. The Committee has endeavored to approach the subject from a broad standpoint and consider matters in relation to the public good rather than from the standpoint of possible injury to the individual.

The following objectives may be set down as the criteria by which existing policies and practices may be judged:

1. The advancement of fundamental knowledge in science and technology.
2. Suitable provision for the application of scientific and technologic knowledge in the service of mankind.
3. The training of men for work in the above field.

The Committee through its members has received statements in regard to the policy and practice of the University of California, the California State Mining Bureau, and the U. S. Bureau of Mines. At the general meeting of the Mineral Resources section, on December 2, 1919, Dr. R. L. Wilbur outlined the general policy of Stanford University in regard to professional activities of members of the university staff. Fragmentary information in regard to the activities of other universities and Government institutions has also been received. In connection with university activities it is to be noted that two fairly distinct matters come up for consideration, namely, what may be termed the official activities of branches of the university, as for example, the farming advisory system of the College of Agriculture of the University of California, and the so-called private professional activities of members of the university staff. In the case of Federal bureaus, such as the U. S. Geological Survey and the Bureau of Mines, regular employees are not permitted to engage in private work, consequently the Committee is concerned only with the work of these institutions as such. Members of these bureaus have at times engaged in private practice when on leave of absence.

*This report is published by the permission, but not, as yet, with the endorsement, of the governors of the Club.

UNIVERSITY ACTIVITIES. Considering first the private professional activities of members of the university staff, work of this sort is ordinarily done during vacation periods or odd hours and consequently the control exercised over it by the institution is likely to be indefinite if indeed it exists at all. That men should feel compelled to undertake such work in order to augment insufficient compensation from the institution to which they belong is, we believe, a condition not consistent with the public good. Outside work when undertaken should be entered into from higher motives than mere monetary reward.

In the field of applied science professional experience undoubtedly enhances a man's effectiveness as a teacher both through the actual knowledge and insight gained and also by the added authority with which he can speak. First-hand knowledge of those qualities which are needed to make a successful engineer is essential. We are disposed to doubt whether the mere visiting of engineering operations can replace actual professional activity from the standpoint just considered.

It is essential also that technical knowledge should be continually advanced through research. Such research to be effective must be based upon an intimate acquaintance with the problems arising in industry. For this reason also something more than superficial contact with industrial activities seems desirable on the part of the university man. This discussion obviously does not apply to research in so-called pure science. The danger that excessive demands will be made for the professional service of university men is to a considerable extent offset by the fact that employers of engineering service prefer in general to command the entire time of their engineers. The Committee finds itself in agreement with the view expressed by Dr. Wilbur that a certain amount of outside professional experience on the part of university men is desirable, but that such work should be taken in harmony with the primary functions of the university, namely, advancement of knowledge and training of students. Moreover the results of such professional work should always be available to the public and professional service should preferably be rendered in connection with public projects.

From the standpoint of both the employers of engineers and of the practising engineers themselves, with whom the university man would appear to compete in his professional activities, the Committee has not learned of anything in existing practice which calls for unfavorable criticism. It is for the employer to determine how he can best secure the assistance needed and the right sort of an engineer need not and will not fear competition from individuals. In substance the primary consideration as regards the professional activity of university men is whether or not such activity increase a man's usefulness

in connection with the work of his institution. Of this the university must be the judge.

Turning now to the professional activities carried on as a regular part of the work of educational institutions, we find an excellent example of this in the comprehensive service rendered by the College of Agriculture, University of California. The Committee is not prepared to express criticism as to the merits of this plan in the field of agriculture. It may be pointed out that the policy which is followed places the institution in direct competition with its own graduates—a condition which would seem likely in time to divert students from the agricultural courses. Moreover, we believe that in general free advice and service are neither of as good quality nor as effective as that for which payment is made.

The Committee's attention has recently been directed to the comprehensive plan announced by the Massachusetts Institute of Technology for technical service along chemical lines. While the final decision as to the merits of this plan will be made on the basis of the results achieved, we are inclined to feel that on the one hand, industrial concerns are not likely to find the service rendered as satisfactory as that obtained from private industrial laboratories and consulting engineers, and that on the other hand, the rendering of professional service on the scale proposed is not likely to prove compatible with the primary educational function of the institution.

GOVERNMENTAL ACTIVITIES. Since State and Federal bureaus are supported by public funds, it is obvious that their proper activities are limited to those which promote the public welfare. As a guiding principle then it may be stated that the public interest should be at least as great as the private interest in any project undertaken by such institutions. In general terms, suitable projects will include work of a fundamental scientific character and technical work, particularly of a pioneer nature, on subjects where the existence of a community or group interest makes it impractical for private individuals or institutions to take up the matter. On the other hand, in view of the great need for constructive work along scientific and technical lines, it seems undesirable in general that the Government institutions should duplicate work which is being competently handled by private enterprise. In reviewing the activities of the Government institutions most intimately related to the mineral industry of this State, namely, the California State Mining Bureau, the U. S. Geological Survey, and the U. S. Bureau of Mines, we find that there is a general conformation to the principles just stated.

It is to be noted, however, that there is within nearly all Government bureaus a pressure for expansion, which at times threatens encroachment on what is now generally accepted as the proper field for private activities. As an example of this mention may be made of the recent suggestion of the director of the Bureau of Standards, before a committee of Congress, that this Bureau undertake the testing of cement for general industrial use.

While expressly withholding comment on the gradual trend toward socialization of industry and speaking par-

ticularly for the mineral industry the Committee believes that the rapid and extensive institutionalizing of engineering service is highly impractical and undesirable. If such a development is to be effective it must come through a slow process of evolution.

Chromite Production in 1919

The maximum domestic production of chromite was reached in 1918, when 82,430 long tons of crude ore was shipped and when 42,687 tons was left in the hands of the miners at the end of the year. In 1919, according to J. S. Diller, of the U. S. Geological Survey, the shipments reached only about 3900 tons, of which about 1000 tons was mined in 1918. The shipments from California alone, chiefly from five producers, amounted to nearly 2000 tons; the remainder was shipped from Oregon, Wyoming, and Maryland.

In Oregon more than 600 tons of chromite, carrying 45% of chromic oxide, was mined in the last half of 1919 and nearly all of it was sold, some of it to consumers as far east as the Great Plains. In California the Placer Chrome Co. moved its mill to the mine and continued concentration in 1919 in the hope of maintaining the industry.

A few tons of chrome sand was washed out in 1919 in Maryland, and prospectors still continue work near the Pennsylvania State line in the hope of finding large bodies of chromite near those that were mined out 40 years ago. Wyoming was the second largest producer in 1919. Although production there has now stopped, a small force of men continues development in anticipation of better conditions.

Prices have been falling ever since the Armistice was signed and apparently have not yet reached the bottom. Lump ore containing 45 to 48% of chromic oxide is selling at 20c. per unit f.o.b. at points in California, and concentrates containing 48 to 50% of chromic oxide are selling at that State for 40 to 50c. per unit. In New York, however, ores containing 35 to 40% of chromic oxide are quoted at 60 to 85c., and ores containing 48% or more are quoted at 70c. to \$1.25 per unit.

The War Minerals Relief Commission is still busy adjusting the claims of those who began the mining of chromite during the War but were obliged to cease operations after the Armistice was signed when further production could not be made at a profit.

The total imports of chromite in 1919, according to the Bureau of Foreign and Domestic Commerce, amounted to 61,404 long tons, which was only 61% of the quantity imported in 1918 and a smaller quantity than has been imported during any year since 1912. Cuba, Australia, Canada, and French Oceania, supplying quantities of ore in the order mentioned, furnished 71% of the total imports. The average price was \$22.49 per ton. The importation of high-grade ore from Guatemala is increasing. Prices may be regulated by the competition of chromite from India with that of Rhodesia, New Caledonia, and Brazil.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

COPPER QUEEN COMPANY EDUCATES MINERS.

DOS CABEZAS.—Several milling plants are either being operated or are in course of construction. The Central Copper Co., which was organized last year, has taken over the Mascot mine and recent development work has opened sufficient ore to warrant the erection of a mill. At the Gold Prince mine a 300-ton mill is rapidly nearing completion. During the past three years a large tonnage of ore has been developed. Ore produced during development has been treated in a small mill which has been leased. The Davies property is also operating a small mill.

KINGMAN.—The Emerald Isle Copper Co. has increased its capitalization from 500,000 to 1,500,000 one-dollar shares to provide funds for further development and construction. It is said that the present 50-ft. shaft and several shallower shafts have developed 200,000 tons of oxidized ore running 2 to 3% copper. About 1000 tons of the ore has been leached and the copper recovered electrolytically. The mine and mill are one-half mile from the Kingman-Chloride branch of the Santa Fe railroad.

TUCSON.—It is announced that the Cerro Colorado silver mine in the Arivaca district is to be re-opened. This mine is one of the oldest in Arizona and up to 1880 had produced over \$2,000,000 in silver. The ore was very rich, containing chloride and native silver. It is in the neighborhood of the Cerro Colorado that the famous Planchas de Platas, the largest lumps of native silver that have been found in Arizona, originated. The Arizona Tucson Copper Co., nine miles south of Tucson, reports the cutting of ore in the new vertical shaft. For several months the company has been shipping ore running high in gold from the glory-hole at the surface, at the rate of one carload per month. Several weeks ago sinking was continued with a view to getting under the orebody, which was being mined through the glory-hole. A crude-oil engine hoist, head-frame, shops, and bunk-houses have been built and preparations are now being made to place the compressor and increase the working force.

A. J. Harshberger, manager for the Arizona Tonopah Mining & Milling Co., situated north of the Arizona Tucson, reports that the main shaft has reached a depth of 145 ft. and has cut ore running high in gold, silver, and copper. In a prospect shaft to the north of the main shaft, high-grade silver-lead ore was struck at the 100-ft.

level. Thirty feet of drifting has been done with encouraging results. It is reported that C. G. Bent and associates of Bisbee have taken over the Papago Chief mine in the southern Baboquivari mountains. There is said to be a large amount of copper-silver ore on the dumps, the mine having yielded high-grade shipping copper ore in the past. A small mill is to be erected on the property immediately.

GLOBE.—During the recent railroad strike the Iron Cap Copper Co. was forced to close down for three days as it is dependent on a branch of the Arizona Eastern railroad to deliver its ore from the mine to the Inspiration mill and the International smelter. The Miami Copper Co. was in a like position, but having ample storage room at the mine for its concentrate, continued to produce and store the output. The Inspiration Con. Copper Co., Old Dominion company, and Arizona Commercial continued operating without interruption. The Van Dyke Copper Co. has passed the 1300-ft. mark in its shaft and is progressing at the rate of six feet per day. It may be recalled that the world's record for shaft-sinking was made in this shaft two months ago. The Old Dominion company is doing extensive development work on the 1800-ft. level on the east side, and on the 1900 and 2000-ft. levels on the west. Some very good new orebodies have been opened in other sections of the mine. The Old Dominion sank from the 1800 to the 2000-ft. level in two shafts. About 7,000,000 gallons per day are now being pumped from the mine. Production averages about 850 tons per day.

JEROME.—A. E. Eldridge, formerly naturalization examiner for the southern district of California, Arizona, and Nevada, under Fred Jones, examiner in charge, has resigned from the Government service to become assistant industrial superintendent of the United Verde Copper Co. at Jerome. His work will be confined strictly to the miners, the principal idea being to get in close touch with the men and endeavor to win their confidence and impress on them the value of co-operation. The William Simpson Construction Co. of Los Angeles has been awarded the contract for the construction of the new hospital for the United Verde Extension Mining Co., on the Hogback in Jerome. The building will be reinforced concrete, class 'A' construction, capable of accommodating 35 patients and built in such a manner that additional wings can be added at any time without disturbing the symmetry of the design. The plans will embody many modern ideas.

BISBEE.—During the month of April, examinations

were given by the Copper Queen for the issuance of certificates to skilled miners who had completed the Copper Queen course in practical mining. Thirty-three men took the examinations and of this number 28 received certificates. The examinations were both written and oral and the student was required to pass with a grade of at least 65% in all tests. It is understood that from now on the men will be required to attend the full course of 35 lectures before they are allowed to take the examination. The certificate states that the possessor "having completed the practical mining course as prescribed by the educational department and passed a satisfactory examination is entitled to this certificate as a testimonial of such attainment and evidence of competency as a skilled miner". It is estimated that approximately 161 men are taking the lectures this year. What may be considered as Arizona's greatest 'legal battle' was concluded on April 30, when the jury brought in a verdict of 'not guilty' in the case of H. E. Wootton, charged with kidnapping in connection with the Bisbee deportations of July 1917. The trial of the 149 defendants in the 'blanket case', likewise accused of kidnapping in connection with the deportations, will commence on June 7.

COLORADO

OUTPUT FROM CRIPPLE CREEK DISTRICT.

CRIPPLE CREEK.—The Empire State shaft of the Isabella Mines Co., in the centre of the Bull Hill area, has been unwatered to the 1000-ft. level and sinking to the 1500-ft. point will start as soon as the contract is let. The Empire will become the main working shaft. The shaft-house, ore-house, and machinery at the Lee shaft were destroyed by fire early in the year.

Cable to permit sinking to the 2000-ft. level, a skip, and other mine equipment for the Blue Flag Gold Mining Co.'s main shaft on Raven hill has been delivered. A station has been cut at 1400 ft. and cross-cutting is now under way. Drifting both east and west is in progress at the 1200-ft. level.

The gross production from mines of the district for April, as reported by the Golden Cycle and Portland mills, and by the district representative of the American Smelting & Refining Co., was 35,295 tons with an average value of \$13.50 per ton, and gross bullion valued at \$473,590. The treatment at the mills was as follows: Golden Cycle, 19,000 tons, average value \$19 per ton, gross value \$361,000; Independence mill at Victor, 15,000 tons, \$3.86 per ton, \$60,000; A. S. & R. smelter at Pueblo, 700 tons, \$75 per ton, \$52,500; total \$473,590. April dividends totaled \$90,000 and were paid as follows: Portland company, \$45,000, Golden Cycle company, \$45,000.

IDAHO SPRINGS.—The milling plant of the Mountain States Silver Mining Co. is to be increased to 300 tons capacity. A California redwood-flume is under construction to conduct water from the company's reservoir on Chicago creek, and when completed water-power will generate 900 h.p., sufficient to operate a plant of larger capacity and furnish power for compressors and electric generators. The mines of the company, the Little Mattie-

Newton group, are situated 2½ miles west of Idaho Springs. Ore-reserves, estimated at 200,000 tons, are reported by D. A. Knight, the company's engineer, with a recoverable content worth approximately \$10 per ton. The company also owns the Silver King group at Georgetown. Plans to extend the line of the Colorado Power company to operate the plant at the portal of the Aurora tunnel are being made. The tunnel will then be extended to cut, at depth, veins exposed in former shaft-workings. The property when operated 17 years ago produced a good grade of gold-silver-copper ore.

BRECKENRIDGE.—Deep snows have curtailed ore-shipments, but with road conditions improved, a good tonnage of ore mined during the winter will be moved. Four of the dredges have resumed work. Lessees on the Germania mine are reported breaking rich silver ore in a vein four feet wide and will soon start shipments from a streak of high-grade silver-lead ore that assays 150 oz. silver. The mill at the Gold Run mine is being put in shape to treat zinc-iron sulphide from the Jessie mine, owned and operated by Geo. F. Roth and associates of Rochester, New York. The Blue Flag Gold Mining Co. has made connection between the Laurium Transportation tunnel and the east workings of No. 1 tunnel. Production will continue and the ore will be brought out through the Laurium tunnel. A vein four feet wide, assaying \$30 per ton in gold and silver, is being developed.

MICHIGAN

COPPER PRODUCTION DURING APRIL.

HOUGHTON.—Production from Michigan copper mines during April declined again. The Osceola Consolidated is an example. The total output for April was only 44,235 tons of which amount 10,500 came from the old mine and the remainder from the Kearsarge. This compares with 50,000 in March and 49,000 in February. Ahmeek produced 64,500 tons in April compared with 68,000 tons in March, and the same tonnage in February. Centennial produced 6750 tons in April compared with 7000 in March, while Allouez did somewhat better than in the previous month. The figures were 20,800 tons as compared with 20,500 in March and 14,321 in February. Isle Royale kept its own mill going at full capacity in April and in addition sent 37,500 cars to the customs plant. Superior did well in April, the best for many months, turning out a tonnage of 1500. There was no shipment from the La Salle during the month.

Although the recently issued annual report of the Calumet & Hecla company does not make an elaborate report regarding the flotation-plant and its operation in the treatment of the product, there is significant assurance of the success of the slime department in the statement that an addition will be built to the present building to provide room for additional settling-tanks. The application of re-grinding, leaching, and flotation principles to the Calumet & Hecla output is confined to the conglomerate-lode ore, and on that product alone has it been found successful. The flotation-plant takes 3000 tons per day. The ore reaches the plant following treatment in

the re-grinding mills and in the leaching process, and more than two pounds of copper per ton is being saved. This is the last word in the recovery from the conglomerate, and when the tailing goes out into the lake at the conclusion of the flotation treatment there is little copper left. The financial profit that the introduction of flotation makes for the Calumet & Hecla may be judged from the fact that conservative figures put the profit from the present limited operation at \$1.50 per share per year in normal times. The copper secured regularly, from the 3000 tons per day that are now handled, is approximately 1,600,000 lb. per year. The use of flotation at the White Pine and at the Winona properties was not war-

foot-wall to hanging. The vein in the south cross cut was 15 ft. wide.

Mohawk's 'rich streak' on the 25th level continues to produce the best ore that is coming from any part of the mine. This is the richest portion of the Kearsarge lode yet opened on the Mohawk property and the shoot is of far greater length on the 25th than on any other level. This streak was opened first three years ago on the 22nd. It was found of greater extent on the 23rd, and on the 24th it was about on a par with the showing on the 22nd. Now at the 25th it is best of all and from the present indications it will take at least four months of steady mining to get out all of the rich ore in sight. No. 4 shaft is

TWIN SHAFTS AND CRUSHER-PLANT AT THE INSPIRATION MINE AT MIAMI, ARIZONA

ranted by the extensive experiments which are conducted a few years ago.

Arcadian Consolidated resumed operations on May 10. This company is not confronted with the difficulty of securing labor. For the present all the men needed are on the property; they are farmers who are working land under lease from the Arcadian company. These men have applied for positions and most of them have previously worked underground and are experienced men. The first work will be undertaken at the New Baltic shaft. Operations in this shaft were suspended in September 1918 owing to lack of capital and shortage of labor. The Baltic shaft is down 500 ft. and the station was cut here. Further openings from this point will be made in the hope that the ore will be on a par with that found in the levels above. The New Baltic shaft made its best showing on the 400-ft. level, which was opened by means of cross-cuts both north and south of the shaft. The north cross-cut showed a 34-ft. vein with heavy mineralization from

being sunk at the present time to the 26th. No. 6 shaft is advancing below the 17th, and at No. 5 drifts are going both north and south. The Mohawk is running 65 drill-machines and is not suffering seriously from the chronic labor-shortage which is hothering some of the mines.

MONTANA

ORE-TRANSPORTATION BY AEROPLANE.

HELENA.—The Liverpool mine, in the Lump Gulch district, will reach a production of 30 cars this month. The new orebodies are holding out well and drifting to the east is following a vein of rich silver ore.

The Amalgamated Silver Mines Co. of Helena has decided to sink the shaft of the Free Coinage mine from 250 to 500 ft. Drifting will progress simultaneously with the shaft-sinking. Ore-shipments are being maintained from the third and fourth levels east of the shaft, and some ground to the west is being mined. Pumping in the

100-ft. shaft of the Stenwinder mine has been discontinued until the arrival of new machinery and in the meantime work is progressing on the extension of the tunnel. The ore mined assays as much as 70 oz. per ton. Sixty feet from the tunnel mouth the vein material pinched down to eight inches but showed a corresponding increase in silver assay. This ore assaying 200 oz. per ton is being sacked and shipped to the East Helena smelter.

BOULDER.—P. A. Danaher and M. Leyding of Helena have taken an option on the Shields-Ironside property situated 12 miles from Boulder. The property is well equipped with a 50-ton concentrator, machinery, buildings, and offices. The mine has been unwatered and shipping will commence soon. The ore contains copper, lead, gold, and silver.

NEHAULT.—Small forces are at work on the Commonwealth, Hidden Treasure, and several other properties both in the Snow Creek and Carpenter districts. Many lessees are operating in the Broken Hill, Gault, Tom Hendricks, and other mines, and an active spring is anticipated.

COOKE CITY.—The operators of this district have been approached by the Alaska Airplane Corporation with a view to contracting for carrying out ore and bringing in supplies while awaiting the completion of a road to Gardiner. Each plane would be capable of carrying six tons of ore. The present cost of freighting by wagon would be cut in half and the acceptance of the proposal is very likely.

J. R. Jackson, judge of the district court, confirmed the sale of the Buffalo-Montana group of mines at Cooke City by R. J. McKay, receiver, to W. D. Marlow. Payments are to be made from operating profits. December 1925 is the date set for completion of payments.

BUTTE.—The Silver Butte Mines Corporation, operating the Corbin Copper Co. properties in Jefferson county, is taking over the property of the Butte-Ballaklava Co. The latter's bonded indebtedness and other obligations will be provided for with cash and stock. Each share of Butte-Ballaklava stock with an additional 50c. can be exchanged for a share of Silver Butte.

NEVADA

LEADVILLE MINES CO. SHIPS CONCENTRATE.

TOBAR.—Seven auto-trucks are hauling a half carload of silver-lead ore daily from the Spruce Monarch, 22 miles south of Tobar, on the Western Pacific in Elko county, and there is 1500 to 2000 tons broken and stored at the mine. The Spruce Monarch was first worked in 1870 and operations continued until 1902, most of the ore being treated in smelters built by different managements. When the price of silver increased the mine was owned by M. Badt & Co., bankers at Wells, and they financed on a small scale the Spruce Monarch Consolidated Mining Co. The old workings could not be entered economically and a tunnel was driven that entered ore 800 ft. from the entrance and at a depth of 400 ft. A raise was driven to the old 300-ft. level, where there was found a 45-ft.

width of ore from which carload shipments give a net smelter return of \$50 to \$70 per ton. Several hundred feet from this orebody another, 35 ft. wide, has been stoped to the 200-ft. level. The tunnel has entered the extension of these ore-shoots and at this depth a drift has been driven over 100 ft. in ore 8 ft. wide and assaying 20 to 40 oz. silver and 25% lead. Further development will be done and if the results are satisfactory it is planned to drive a 7500-ft. tunnel at a depth of 1500 ft. on the dip. Reports indicate that the Spruce Monarch is fast being developed into a mine. The vein extends into the adjoining claims of the Ada H. company, which are credited with an early-day production of \$70,000 in high-grade ore, and this company has started prospecting on a good scale. The Bullshead Mining & Smelting Co. owns the Bullshead mine and a 30-ton smelter, which was operated successfully early in the winter. There is estimated to be \$650,000 worth of ore in the mine and dumps. The company recently considered the sale of the mine and smelter for \$265,000. The management plans to drive a tunnel to cut the veins under the present levels.

LEADVILLE.—The first carload of concentrate from the re-built 50-ton plant of the Leadville Mines Co. was made a few days ago to the smelter at Murray, Utah. The plant was started on March 15 and since then it has been treating 20 tons of \$40 lead-silver ore daily, producing from this tonnage 5500 lb. of concentrate assaying \$200 to \$250 per ton. The Leadville, formerly the Tohoqua, is an old mine credited with a net production of \$156,000 under former management, the ore coming from above 350 ft. The ore now being mined is taken from tunnel and shaft-workings which are connected. The concentrator is at the entrance to the tunnel. A winze has been sunk 300 ft. from the tunnel and lateral work from the bottom has been started. The winze reaches 160 ft. below the bottom, or 500-ft. level, of the shaft and the finding of the extension of the ore-shoot now being mined would indicate a big reserve. The main vein of three feet by the tunnel has an average width of more than three feet and it extends through three claims for 3000 ft. The vein is principally quartz, the ore containing lead and silver sulphide, with small quantities of gold, zinc, and iron.

DIVIDE.—An orebody 100 ft. long that has been cross-cut for 12 ft. has been found 500 ft. south-east of the shaft on the 585-ft. level of the Tonopah Divide. The ore contains silver glance and it is the first important shoot of sulphide ore found in the mine. A winze has been sunk 40 ft. in high-grade ore. The 585-ft. level is at least 400 ft. above the water-level, according to the latest estimates. This is the first important shoot found on the 585-ft. level, which is the deepest on which lateral work has been done. The position of the ore is said by engineers to indicate that it has a more decided rake into the Gold Zone than was at first indicated. Failure to find ore on this level had been the subject of much discussion. A number of prospects closed during the recent labor trouble have not re-opened and the consulting engineer for several of the active companies states that he does not think there are more than a dozen mines being worked in the district. The

affairs of the Tonopah Divide for the last year continue to be discussed widely, particularly the opportunity afforded those on the 'inside' to speculate in the stock. Mining men describe as a 'fiasco' the rise and decline of the stock when taken in connection with the two mine reports and they feel that a sentiment has been created which will do injury to the mining industry in the State. The silence of the management over many months during which there existed a condition almost without parallel in the history of mining, coupled with the decline in the price of the stock and the alleged 'leak' in the last report, is eliciting some criticism.

GOLDFIELD.—Cross-cuts have been driven north and south for a total of 220 ft. from the west cross-cut on the 358-ft. level of the Florence. The west cross-cut has been stopped at a point 1061 ft. from the shaft. The drifts are being driven on a vein 21 ft. wide, from which good

Western Ore Purchasing Co. at Hazen. Excavations are under way at the property for six new buildings to house men with families. Cross-cutting from the 530-ft. point in the shaft of the Simon Contact property which adjoins the Simon Silver-Lead on the north is under way to explore for the downward extension of the ore opened on the 250-ft. level. Two shifts with machine-drills are employed.

OREGON

DEVELOPMENT OF THE CALIFORNIA MINE.

JOSEPHINE COUNTY.—A. Walker and H. P. Campbell are associated in developing the California mine 18 miles from Glendale. The property is situated near the Gold Bug and Copper Stain properties, and is equipped with a two-stamp sampling-mill. The vein averages four feet in width and runs \$23 in free gold. They have spent

50-TON CONCENTRATOR OF THE LEADVILLE MINES CO.

assays are secured, but ore has not been found. In working toward the Aurelia-lease shaft from the south-east cross-cut on the same level to secure air, a 17-ft. vein of quartz has been found. The south-east drift is 925 ft. long and little work will be done in it until the shaft has been reached.

MINA.—The main working shaft on the Simon Silver-Lead property has reached the 600-ft. point. A skip-pocket and a station are to be cut and laterals driven to prospect for the downward extension of the orebodies opened on the 400-ft., or sixth level. High-grade silver-lead ore, low in zinc, is being broken in a winze on the fifth level. The winze is being driven to determine the rake and dip of the ore-shoot in order that it may be cut on the sixth level. A earload shipment, purely as an experiment, was sent out recently from which the following smelter returns were received: 31.8 oz. silver, 31.9% lead, and 9.3% zinc. The dry weight was 73,483 lb.; net weight, 74,300 lb.; gross settlement, \$76.55 per ton; net returns, \$68.12 per ton. The shipment was sent to the

\$50,000 in development work and have run a cross-cut 651 ft. long at a depth of 300 ft. There are also drifts totaling 230 ft. on each side of the cross-cut. Work on the property was discontinued during the War, but was resumed last winter. The elevation of the mine is about 2500 ft. Aside from small deposits of stream gravel the rocks of the area are either Jurassic sediments or igneous intrusives. The general strike of the sediments and also of the contact between the sediments and igneous rocks is about N. 20° E.; the sediments dip steeply to the east. The ore is white quartz containing some pyrite.

GOLD HILL.—It is reported that William Piggott, of Seattle, who several years ago acquired control of the Oregon Iron & Steel Co.'s Oswego plant near Portland, has recently purchased the iron mine owned by the Garfield Iron & Lime Co., situated two miles north of Gold Hill, and that he will re-open the old workings and ship the ore to the Oswego plant. This iron deposit is within a mile of the main line of the Southern Pacific railway at an elevation of from 1850 to 2250 ft. The deposit con-

sists of limonite, hematite, and magnetite, occurring in lenses in Paleozoic sediments, which include some limestone and abundant argillite. The sediments are cut by a dike of granite. The history of the deposits dates back to the year 1870, when the locators, practical iron-ore experts, hauled several tons to Sacramento, the nearest rail point, and shipped it to Wales. The report on this test-shipment demonstrated that the ore was a high-grade hematite. During the early '80s two iron-experts, Burgess and Pomeroy, acquired the property, did some development, and made shipments, but on account of the low price of ore and the high transportation charges they abandoned the project. Later the property fell into the hands of the Garfield Iron & Limestone Co., a Portland concern, that has let it lay idle since.

JACKSONVILLE.—The Blue Ledge copper mines in the Upper Applegate district, 40 miles out from Jacksonville, have resumed the shipment of three cars per week to the Tacoma smelters. The mine employed about 30 miners during the winter, while shipments were suspended, developing new ore. The scarcity of auto-trucks and teams this season will cause an increase in the cost of the haul to Jacksonville over last season's price of \$10 per ton. The shipments consist of ore running better than 12% copper and \$7.50 in gold and silver, while the lower grade ore is dumped at the mine for future reduction.

UTAH

PROGRESS AT THE TINTIC STANDARD MINE.

SALT LAKE CITY.—The threatened I. W. W. strike in the metal-mining camps of the State, set for May 1, failed to materialize. Floyd T. Jackson, special agent of the Department of Justice in this city, said the strike threatened to involve every mine at Bingham, Park City, and Eureka, as well as some other parts of the State. Walking delegates, it is stated, were dispatched from Butte to Bingham to promote the cause of the striking miners in Montana. On the afternoon of April 30 a raid was conducted under the direction of Mr. Jackson, and nineteen I. W. W. delegates, who had been agitating among the miners at Bingham, were arrested. Large quantities of literature carried by these delegates to assist in promoting the strike at Bingham, were seized in raids on their homes and lodging places, and a printing establishment in Salt Lake City, where sundry literature was being printed, was likewise raided and the proprietor arrested. The I. W. W. could not hope to call out the miners at Park City or Eureka without first getting the Bingham miners to strike, according to Mr. Jackson, and with this in view they were launching their greatest efforts at Bingham. The agitators arrested will be prosecuted by the county attorney under the State syndicalism act.

The local assaying offices have announced a new price list for umpire assays, which averages about 30% over the former prices charged for such work. The assayers and chemists claim that, in many cases, labor and material costs have risen from 100 to 300%, and that they are compelled to make the increased charges.

BINGHAM.—Steady progress is being made in development at the property of the Bingham Tooele Mining Co. This property is situated in Middle canyon, seven miles from the International smelter at Tooele and about 1000 ft. from the mouth of the Utah Metals main tunnel. To the north and east of the thirteen claims owned by the company is the property of the Utah Metals Co.; to the south and west lie the Black Diamond and Midway groups, which were acquired by Jesse Knight last summer. The Bingham Tooele company is doing pioneer work in the hope of finding orebodies similar to those in the Bingham district. During the past year the adit, which is now in a distance of 1752 ft., has cut six different strata of lime. The first three were hard black lime, the next two were soft black lime, while the last is blue lime, much softer and more soluble than any cut previously. The quartzite also is softer, and the management is confident that an orebody will be found at the contact of the quartzite, or of the monozite dikes which cut the beds.

On May 2, about 100 miners at the Utah Apex were refused admission to the mine by V. S. Rood, superintendent. The men had been arriving late to work for several days, and Mr. Rood informed them that if they could not report on time, the mine would be closed until a new crew of miners was secured. The men state that they want eight hours from collar to collar, whereas the management insists that they enter and leave the mine on their own time. At last accounts, the men were gradually returning to work on the basis of the company's terms.

PARK CITY.—The latest departure at the Silver King Coalition mine is the use of diamond-drills to explore new ground. This was started several weeks ago, and is giving excellent results. A new fissure system is being developed which promises well. The King Coalition is said to be in better shape now than it has been for a number of years. The company has 200 men and is making a good production record, although it is not as large as the management would like, and at least 100 additional men could be used. The camp could easily use 500 men at the various mines if they were available. The milling plant of the King Coalition is being remodeled, and the first half is completed. This section is treating between 300 and 400 tons of ore per day. The management is considering the adoption of a flotation process to treat the fine.

TERCOMA.—Conditions at the Tecoma Consolidated mine, near here, improve as progress is made; two headings are now being run. The main tunnel, called the 'Woodward', which will connect with the winze being sunk from the upper workings by the Utah Zinc Co., and at the same time intersect several veins at depth, is being driven steadily. The other heading, a drift from the Woodward tunnel, is being run on a good vein, which at last reports was three feet wide and averaged 30% lead and 8 oz. silver per ton. This drift intersected the fissure at a distance of 650 ft. from the portal. The face of the Woodward tunnel, which at present shows some

quartzite and iron pyrite, is approximately 800 ft. from the portal. At a distance of 300 ft. a raise will be put up to connect with the winze which is being sunk by the Utah Zinc Co. This latter company has a long term lease upon the large zinc deposit blocked out in the old workings of the mine. As soon as this connection is made, shipments of zinc ore to the plant being constructed at Murray, Utah, will begin.

EUREKA.—During the first quarter of 1919, the Tintic Standard Mining Co.'s output totaled \$891,033. The value of the gross production to the end of 1919 was \$5,107,619, making the grand total up to April 1, of this year, \$6,001,652. Recent shipments from this property have been netting from \$6500 to \$8500 per lot of four standard cars. All of the ore so far shipped has come from the 1250 and 1350-ft. levels, in an area 700 ft. long by 400 wide. The 1450-ft. level is now being developed and the work so far done shows the ore to be equal in extent and value to that found on the two upper levels. Besides the straight shipping ore already developed, there is approximately 800,000 tons of milling ore proved up, for which the company is now constructing a concentrating plant. During the past few months, diamond-drilling operations from the No. 1 stope have prospected a copper deposit on the 1100-ft. level, and 28 ft. of ore that averages 6% copper and 17 to 22 oz. silver per ton has been penetrated. A drift is now being run to open this ore. No. 1 shaft has been deepened to the 1250-ft. level, and two drifts are being run from it to the east and south-east. Machinery has been ordered for the sinking of No. 3 shaft in the mineral channel, a distance of 1700 ft. north-easterly from No. 2. E. J. Raddatz, president, is of the opinion that it will take from three to five years to bring the property up to full production. At the present time its output is limited by shaft capacity, and when the No. 3 shaft is completed, the production can be increased.

BRITISH COLUMBIA

PREPARATIONS FOR A SEASON OF ACTIVE DEVELOPMENT.

STEWART.—Recent development on the L. L. & H. group of claims, situated on Bitter creek in Bear River valley, has exposed an orebody 27 ft. wide, according to C. N. Tubman, who, with E. M. Molander, one of the original stakers of the Mount Sicker properties on Vancouver Island, bonded this group last February from J. S. Hartley. The ore contains copper, silver, lead, and gold. When Messrs. Tubman and Molander went to work on March 14 they found that two tunnels had been driven, one for 40 ft. on the upper or galena lode and the other for 200 ft. on the lower or arsenical lode. The former cross-cut the lode and the latter had struck the vein and had been carried forward in ore for a distance of 17 ft. The L. L. H. is about 16 miles from Stewart and it is the intention to carry on development throughout the season now opening.

ALICE ARM.—Miners employed by the Taylor Mining Co. at the Dolly Varden mine left their work on April 22 and on May 3 are reported to be still on strike. Negotia-

tions are under way which, it is hoped, will result in the resumption of operations. As matters stand both the actual mining and the railroad, which furnishes transportation between tidewater and the mine, are tied up. The men's demands are for a raise in wages from a minimum of \$5 per day to \$6, single cot bunks, scrubbing of camps, and free blankets and sheets. The company's rate of board is to remain at \$1.25 per day. This ultimatum was presented to the management, it being specified that three days would be allowed for a decision. It was announced that under no circumstances could the demands be allowed and that rather than submit the whole work-

THE MINING DISTRICTS OF SOUTH-WESTERN OREGON

would be permitted to cease. The men accordingly stopped work.

NELSON.—Rich samples of mineral have been taken from the upper workings of the Utica mine. They are from a vein between five and six feet wide and represent a rich stringer two feet wide, the latter being of gray copper with ruby and native silver, assaying from \$100 to \$1000 per ton. Mining of the entire lode should give ore containing 500 to 600 oz. of silver per ton.

CRANBROOK.—A. J. Palmquist, manager for the Wild Horse Creek Mining Co., who has been spending the winter in Texas, has returned to British Columbia and is making preparations for the resumption of placer mining on Perry creek. The company did preliminary work last season in the way of repairs to flumes and machinery so that washing operations should be started in the course of a month.

REVELSTOCKE.—Recent development at the Lamark mine, an old and well-known property near here, appears to confirm the faith and judgment of the present owners, Fred C. Elliott and William Dornberg. At a depth of 1000 ft. on their vein they have opened up a body of ore

containing a high-grade streak from two to four feet in width, with about six feet of milling ore. The high-grade averages 90 oz. silver and 65% lead. The vein has been drifted on for 30 ft. and holds its width and value. In addition it is asserted that a vein of high-grade gray copper has been exposed on which little work has been done. During the winter ore has been blocked and the Lanark now is ready to commence production. Since Messrs. Elliott and Dornberg have acquired control they have built a modern hydro-electric plant and a concentrator.

PRINCE RUPERT.—C. A. Banks, of the British-Canadian Silver Corporation, that recently acquired a large interest in the B. C. Silver Mines, Ltd., and the Bush Mines, Ltd., both in the Salmon River district, has gone to Stewart to plan the summer's development at the two properties. H. L. Batton, formerly with the Consolidated M. & S. Co., has been appointed manager at both properties. A considerable amount of diamond-drilling will be done. Burdie Brothers & Brett, Ltd., has taken an option on the American Boy group, at Nine-Mile mountain. The present shaft will be sunk to the 300-ft. level. R. H. Stewart, of Vancouver, is acting as consulting engineer to the firm. The tunnel at the Silver Standard mine, near Hazelton, has cut the No. 2 vein, exposing two feet of milling ore. The last 100 ft. of drifting has cut six stringers of solid sulphide ore, and it is probable that these will be developed when the tunnel has reached its objective, the main vein. Quite apart from its use as a working tunnel, the adit has been a success from an exploration point of view, as it has cut a number of rich stringers. A gasoline engine is being added to the mine equipment to supplement the water-power, which at times is inadequate.

A first payment of \$67,000 has been made by a syndicate of Vancouver men on the Silver Tip group, in the Salmon River district. Development will be started by R. Lacey as soon as weather conditions permit.

ONTARIO

NIPISSING SHAREHOLDERS PROTEST.

COBALT.—Shareholders of the Nipissing Mining Co., at the annual meeting, expressed the opinion that larger dividends should be paid. In support of this, they pointed to the surplus of \$4,372,952 as compared with \$1,980,126 in 1916. The increase of nearly a million and a half occurred during the three years in which the price of silver increased most rapidly. In reply, company officials pointed out that the greater part of the increase had been invested in Government bonds, which as a matter of principal they do not wish to sell at this time.

A. J. Young, president of the newly incorporated Bailey Silver Mines Co., has issued a statement in regard to the estimated earning power of the old Bailey-Cobalt mine as well as the Northern Customs Concentrator, both of which come under the ownership of the newly formed company. Mr. Young declares ore in sight contains 510,294 oz. of silver or an average of 22 oz. per ton. Costs of operation are placed at \$8 per ton, recovery at 85%, and daily tonnage at 50, and from this it is calculated that a net profit of \$768 daily may be realized. As regards the

newly acquired concentrator, this is already earning an average of about \$250 net profit daily, thus indicating a total earning power of \$1018 for both mine and mill. The estimate does not include probable ore and also omits the large tonnage of ore lying in the dumps. The British interests, owners and operators of the old Keeley mine in South Lorrain, have acquired an option on the adjoining Beaver Lake property. Two cash payments have already been made on the option price. The plan of the joint operation of the two properties is quite elaborate, and will include driving the main shaft to the contact at a depth of from 350 to 400 feet.

POREUPINE.—At the Davidson the vein has been followed on the 500-ft. level for a distance of 460 ft. The width varies from 27 to 53 ft. of ore of a good grade. The present mill being only a small one designed for testing purposes, the building of a large modern mill with cyanide equipment is being considered. Plans are under way at the Gold Reef for sinking a shaft to develop orebodies indicated by diamond-drilling. The Clifton-Poreupine is drifting on the 200-ft. level, where the vein shows up equally well as on the 100-ft. level, and a good tonnage of ore is in sight. A drift has been started northward toward the basalt formation where the indications are regarded as favorable. The North Davidson, having secured funds for development on a large scale, has arranged for a supply of electric power and is erecting a mining plant and putting up camp buildings.

KIRKLAND LAKE.—The main shaft of the Ontario Kirkland is down 450 ft. When a sump is completed to the additional depth of 20 ft. a working station will be cut and cross-cutting undertaken to reach the orebodies developed on the 300-ft. level. One of these shows an average gold content of about \$20 for a distance of 100 ft., and the other averages about \$12. Unofficial estimates place the value of the ore opened up at about \$500,000. A mill is planned but definite steps toward it have been deferred until the results of development work at the 450-ft. level are known. The Kirkland Lake management has decided to drift toward the western boundary, operations hitherto having been largely confined to the eastern half of the property. The work will be at the 500-ft. level. The main shaft will be put down to 900 ft. At the Wood-Kirkland property in Lebel township a thorough exploration of the surface is being undertaken and test-pits will be driven on veins already found. The shaft of the Elliott-Kirkland will be continued from its present depth of 500 ft. to 700 ft. at which level lateral work will be carried to reach the porphyry-conglomerate contact, some little distance to the north. The Wright-Hargreaves is resuming operations, employing about 45 men. The workings have been unwatered and development will be pushed during the period of construction of the new mill.

SESEKINIK.—The Jensen farm, on which gold was discovered some years ago, has been taken over under option by Detroit interests and a company organized known as the Golden Summit. Two narrow veins were found on the surface, on which test-pits were sunk and at 18 ft. one of the veins had widened to two feet.

ALASKA

Juneau.—The Alaska Treadwell Gold Mining Co. has taken a bond on 12 gold-quartz claims at Nixon fork, near McGrath on the Kuskokwim river. An outfit costing, it is said, in the neighborhood of \$17,000, is being assembled here by the company for transportation to the Kuskokwim. A portable air-compressor, drilling-machines, and other equipment is included. Livingstone Wernecke, geologist for the Treadwell company, left for McGrath several weeks ago. He went to Seward and then traveled 12 days by dog team to his destination. His report on the claims is said to have been favorable and he was authorized to go to work. He has been working with a crew of 12 men ever since in opening up the prospects.

CALIFORNIA

Redding.—It is semi-officially stated that the Bully Hill company will erect extensive reduction works at Winthrop this summer. Preliminary topographic surveys for the buildings are being made. The options given by the Bully Hill Copper Mining & Smelting Co. to Walter Arnstein in January 1917 for the mines and the Sacramento Valley & Eastern railroad, extending from Pitt on the Southern Pacific to the mines, were filed for record last week. Arnstein was to pay \$500,000 for the railroad, \$100,000 each year, and \$250,000 for the mines, 25% of the smelter proceeds on all ore extracted to be applied on the purchase price. A large amount of ore was treated under the option. It seems certain that the option has been taken up and that the Bully Hill Mines, Inc., the corporate successor of Mr. Arnstein, soon will become the owner of both railroad and mines.

COLORADO

Breckenridge.—A unique feature of the Royal Tiger Mines Co.'s operations is the recognition of the American family-man as an important factor in the economic success of mining enterprises. A married man's compensation is fifty cents per day more on most of the work than that of the single man. A first-class school, teaching all grades, is partly maintained by the company. A mercantile establishment, strictly co-operative, is backed by the company and on April 1 a refund of 10% to all the employees was made on their past purchases. The company is entering the productive stage, having a pilot-concentrator in operation and a 600-ton concentrator nearing completion.

Idaho Springs.—Lessees on the Freeman mine in Gilson gulch have opened up 2½ ft. of silver-lead ore with an average value of \$40 per ton. The property is one of the Silver Age group.—W. Krape and Denver associates operating the Hecla on Cavallo mountain have opened up gold ore assaying 9 oz. per ton. Shipments are now being prepared.—Bodies of milling ore are reported discovered on property of the Silver Mountain company in North Empire. A good tonnage awaits the opening of roads to ship ore to the mill.—The Newton and Hudson mills have resumed operations.

Mayday.—The Jumbo Mining Co. has purchased three claims from Thomas Hues, a prospector of this place, for a consideration of \$10,000. These claims join the Jumbo on

the south and it is said that the face of a drift in the workings near the Jumbo Hue line shows good ore. Development work will be done here this summer.

NEVADA

Eureka.—The Ruby Hill Development Co. has just reached the water in its shaft after re-timbering the bad portion below the 900-ft. level.—The Holly shipped four cars of ore and is loading others. The railroad strike held up operations somewhat.—Lessees on the Holly Extension are taking out a little high-grade ore which they recently opened.

White Pine County.—H. Z. Peters, engineer for a newly formed company headed by R. G. Ward, has examined the Ward mine that adjoins the famous Eberhardt, one of the bonanza mines of Hamilton, considered to be the richest silver camp of the old days. It comprises 17 mining claims covering approximately 230 acres, part of which is patented ground. The deep Eberhardt tunnel that was driven nearly a mile into Treasure hill many years ago by the English company which owned the Eberhardt mine, runs within 300 ft. of the southerly end of the Ward mine and permission will be sought to work through this tunnel. In addition to 2000 tons of milling ore on the dump, there is estimated to be \$200,000 worth of ore blocked ready for stoping.

NEW MEXICO

Pinos Altos.—The new mill of the Calumet-New Mexico Mining Co. is doing well on the complex zinc-lead ores that it treats. One car of lead concentrate shipped to the smelter at El Paso sampled before shipping: 3.73 oz. gold, 25.25 oz. silver, 1.61% copper, and 52.0% lead.

OREGON

Gates.—We are informed that the Lotz-Larsen Mining Co. has opened a body of chalcopryite ore that assays 8.88% copper, 0.2 oz. gold, and 2.56 oz. silver. An adit 600 ft. long, driven the past winter, has followed ore all the way. The company controls 29 claims on which 3000 ft. of tunnel work has been done. Two cars of ore shipped assayed 10% copper with gold and silver worth \$7.80, and more will be shipped when the road is improved.

UTAH

San Juan County.—Leaching copper ores by means of sulphurous acid is to be tried at the Big Indian mine near La Salle. This property is owned by C. E. Loose and associates of Provo. It is estimated that approximately 300,000 tons of 3% copper ore is developed. The copper occurs in sandstone which is unusual. The mill now under course of construction is of 300 tons daily capacity. Construction has been under way since last summer and it now appears that the mill will be completed and ready for its initial run about the first of July. At present a crew of 15 to 25 men is employed. All of the iron parts in which the leaching solution is used have been lined with lead and all of the bearings which run in the solution are made of bronze. The ore is leached in a sulphurous acid solution, the solution being warmed by steam-ripen running through the tanks. The copper solution is then precipitated and the precipitates smelted into bullion.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

J. Mackintosh Bell is at Cobalt.

Seeley W. Mudd has gone to New York.

C. F. Nourse has gone to Eureka, Nevada.

James W. Neill came from Pasadena to San Francisco last Monday.

W. F. Rock, of Denver, has gone to Wassilla, Alaska, for six months.

J. L. Diller, of the U. S. Geological Survey, has been visiting Globe, Arizona.

R. S. Fitch has moved from Knob Noster, Missouri, to Leadville, Colorado.

R. F. McElvenney, manager of the Garfield smelter at Garfield, Utah, is in New York.

James A. Farrell, president of the United States Steel Corporation, is in San Francisco.

Harvey S. Mudd passed through San Francisco on his way from Los Angeles to Wallace, Idaho.

George D. Londerback, **A. Warner Lawson**, and **E. J. Schrader** were in Salt Lake City recently.

S. A. Holman, manager for the Balaklala Consolidated Copper Co., has returned to Coram, from Oakland.

George B. Agnew, president of the North Star Mines Co., is on a visit to the mine at Grass Valley, California.

F. A. Foster, Professor of Mechanical Engineering in the University of Peking, arrived in San Francisco last week.

Paul T. Bruhl, recently mill-superintendent for the American Venture & Mines Corporation, has gone to Honduras.

Cecil J. Brooks, metallurgist to the Simau Mining Co., of Benkoelen, Sumatra, sailed from San Francisco on May 7.

E. L. Young has been appointed assistant general manager for the Sunnyside Mining & Milling Co., at Eureka, Colorado.

C. Colcock Jones has returned to Los Angeles from mine examinations in the Yellow Pine mining district of Nevada.

William C. Madge is now engineer and assistant general manager to the Tintic Standard Mining Co., at Tintic, Utah.

Masaki Ito, chief engineer of the Besshi copper mine of the Sumitomo company, Japan, is visiting the Bisbee district.

Charles A. Mitke is in the Globe-Miami district, in connection with the ventilation of the Miami and Inspiration mines.

C. H. Besch has left the Royal Technical College of Glasgow to assume the chair of metallurgy in the University of Sheffield.

Lloyd C. White has returned to San Francisco from Shasta county, where he has been on one of his regular trips of inspection.

E. J. Mehren, editor of the 'Engineering News Record,' has gone to Europe to study conditions in England, France, and Germany.

E. L. Newhouse, Jr., and **S. M. Soupcoff**, of the Utah Department of A. S. & R. Co., are visiting various Nevada mining districts.

H. J. Glennon, formerly store-manager for the Moctezuma Copper Co. at Nacozari, Sonora, Mexico, has leased the Belen mine, south of Nacozari.

Kimio Hayashi, Chief of the Labor Department of the Furukawa Mining Co. of Japan, is making a three months visit to the United States for the purpose of studying labor

conditions. He spent several days in Utah and Montana recently.

Walter Larsh, underground superintendent for the Nevada Consolidated Copper Co., has been visiting the copper mines at Miami and Ray.

J. Nelson Aevius, of Pasadena, California, who has been incapacitated by illness for nearly a year, has recovered and is able to accept engagements.

Walter Gross, superintendent of the A. S. & R. Co.'s copper refinery at Perth Amboy, New Jersey, was in Utah recently, visiting the company's smelters.

D. C. Jackling left New York on May 8 on his return to San Francisco. He visited the Mesabi iron mines in Minnesota and the Butte & Superior at Butte.

C. E. Mills, former general manager for the Inspiration Con. Copper Co., spent several days during the latter part of April looking over the Inspiration property.

Charles L. Harrington is now at the Denver office of the Radium Company of Colorado. He was for the past two years mine superintendent at Naturita, Colorado.

William Rogers Wade has tendered his resignation as mine superintendent of the Pilares mine of the Moctezuma Copper Co., at Nacozari, Sonora, Mexico. He is now in New York.

Frank Ayers, who recently received his discharge from the U. S. Army, has been appointed mine superintendent of the Pilares mine of the Moctezuma Copper Co. at Nacozari, Mexico.

Joseph T. Singewald, Jr., Professor of Economic Geology in the Johns Hopkins University, who has been engaged in geologic investigations in Peru during the past five months, has returned to Baltimore.

Gerard De Geer, superintendent of the open-hearth and electric steel-furnace department of the Stora Kopparbergs Bergslag, in Sweden, is making a tour through the United States. He was in Utah recently.

Obituary

John Christy, mining engineer of Clifton, died at Gila Bend, on April 14. He was well known in mining circles both in the Clifton-Morenci and the Globe-Miami districts, and was equally prominent in political circles, having been a former member of the Arizona State Legislature.

Edward O. Kennedy, a pioneer in the Globe district, died on April 25, at the age of 83 years, in St. Joseph's hospital, Phoenix, Arizona. He was born in New York, but went to Colorado in the early '60s. A few years afterward he went to Silver City, New Mexico, and in the fall of 1876 he went to Globe, where he was superintendent of the first Old Dominion smelter, a few miles west of Globe. He also had charge of the Stonewall Jackson mill at McMillen for a time, and built and operated the first custom smelter in the Globe district.

EASTERN METAL MARKET

(By wire from New York)

May 10—Copper is quiet and slightly easier. Lead is quiet and lower. Zinc is stagnant and soft.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 8, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 40 45 pence per ounce (925 fine), calculated at the normal rate of exchange.

SENATE HEARING ON THE COAL INDUSTRY

Seasonal rates on coal as a means of equalizing production and distribution to avoid famines caused by strikes or bad weather were endorsed by the public interest by Interstate Commerce Commissioner Clark and Director Smith of the U. S. Geological Survey in testimony before the Senate Coal Committee. George H. Cushing, Director Wholesale Coal Association, George Heaps, representing Iowa Coal Operators Association, and C. E. Lusher, editor of the "Coal Age," formerly of the Geological Survey, while favoring the end desired opposed seasonal rates as being impracticable. Senator Freshmeyer declared the public has exhausted its patience over high coal prices and inability to get coal when most needed, and insisted that Congress must "put its arm around the industry" and prescribe that it would do so "in twelve months." Hearings point to probable centralization of authority over coal in Interior Department under an assistant secretary, whom the Senator says must be a man of vision and of leadership capable of dealing with operators, miners, and the public on problems involving labor, storage, transportation, and prices. The Senator expressed impatience over opposition to plans designed to provide the country with an adequate supply of coal at all times, declaring that the same people who appealed for assistance last winter are now opposing measures drafted as a result of those experiences and intended for their relief.

Director Smith declared that to allow present conditions to continue was to invite industrial paralysis. The mines and railroads must handle more coal in the summer to relieve the heavy burden of fall and winter. At present from 35 to 60% more coal is mined in November, the highest producing month, than in April, the lowest. The coal business would be helped and miners, operators, and consumers benefited by surer supplies of cheaper coal.

Commissioner Clark said the Commission unanimously favored seasonal rates. The bituminous industry was over-developed. Present situation resulted in congestion of terminals because of the re-consumption practice. He favored reductions in rates in cents per ton rather than on the percentage basis. Seasonal rates would reduce prices for coal due to resulting competition. With a perfect car service prices would drop in a week and result in a production 40% greater than the demand. The Commission did not have power to prescribe seasonal rates.

Mr. Cushing said change in rates must come through evolution rather than revolution. Equal monthly production and consumption of coal would involve a storage program contrary to business tendencies, and difficult of realization. He said coal mining was intermingled closely with farming and 100,000 coal miners are required in farming and industrial work in the off-season. Storage could not be induced in summer as the industrial program was not known until after the final crop report about July 15. Storage in large cities was difficult because of lack of space and coal could not be stored in bulk on account of fire risk and it was more valuable for other commercial uses than storage of coal. Coal stored under water would probably be frozen when it was needed. He thought there were about 3000 to 4000 coal mines and suggested government regulations of the number of mines as a possible remedy. He said that seasonal rates might apply on anthracite coal, as it was mainly for household use and was capable of storage.

MONEY AND EXCHANGE

Foreign quotations on May 11 are as follows:

Sterling, dollars:	Cable	3.85 1/2
	Demand	3.85 1/2
France, cents:	Cable	6.61
	Demand	6.61
Lire, cents:	Demand	5.00 1/2
Marks, cents:	Demand	2.01

Eastern Metal Market

New York, May 5.

All the markets are inactive and are still suffering from the effects of the railroad and other strikes. Prices are fairly steady in most cases.

The copper market is inactive but steady. Stocks are gradually growing less and some refineries are closed.

The tin market continues quiet. There is some interest by consumers in future shipments but features are absent.

But little change is noticeable in the local market for lead and prices are steady.

Demand for zinc is very light but prices are fairly steady.

Antimony is lower and inactive.

IRON AND STEEL

Considering the industry as a whole, railroad shipments of iron and steel have improved, says 'The Iron Age'. The exception is the Pittsburgh district and the Valleys. Much of the betterment is due to concentration on routing and on making up solid trains, for the return and replacement of railroad labor is proceeding slowly. While some plants are operating at 80% capacity others are not above 20%.

The closing of the gap between the Steel Corporation prices and those of the independents is shown in Chicago district sales. Plates have been sold for last-half delivery at 3c., Pittsburgh; quotations of 3.25c., 3c., and 2.75c., Pittsburgh, are reported commoner on shapes and a minimum of 3c. has been named by Eastern independent producers on bars, with 2.75c. in exceptional cases.

COPPER

An announcement of interest is the definite arrangement, concluded on Monday, for financing purchases of American copper by France. This has been in the air for some time as well as a like plan for other countries. Purchases by France, Germany, England, and other foreign countries continue of fair proportions. Exports of copper to Germany last week were 2782 tons out of a total of 5760, Great Britain being second with 2283 tons. The domestic market is still inactive with prices largely nominal. Leading producers continue firmly to maintain quotations for Lake and electrolytic copper at 19.25c., New York, for early delivery. For third-quarter they ask in some cases 19.50c., but very little business is reported. The outside market still exists at around 18.50 to 18.75c., New York, for electrolytic for May and June, but almost no business is recorded. The future of the market is hard to predict because of the fact that some large refineries have been obliged to close on account of the railroad, mines, and other strikes. This will at least delay deliveries on contracts, particularly by those who have their copper refined on toll.

TIN

The market is featureless and quiet but less erratic. Labor conditions continue to depress. This, together with the transportation mix-up, and the car shortage, has caused consumers to stay out of the market. There has been therefore but little buying of any kind. On Friday last about 150 tons of future shipments was sold on the Metal Exchange at 59 62½ to 60c., depending on the position. Consumers are showing some interest in future shipments and there is stated to be a dormant inquiry of proportions which may develop into business any day. Quotations for spot Straits have been steady the past week at around 61c., New York, and the quotation yesterday was 60.25c., New York. Deliveries into consumption in April are returned as 3305 tons, of which only 605 tons was credited to Pacific ports. The quantity in stocks and landing on April 30 was 2676 tons. Tin imports to May 1 have been 16,783 tons as compared with 6341 tons to May 1, 1919. The arrivals thus

far in May have been 1380 tons, with 1741 tons reported afloat.

ZINC

The market continues in its lifeless condition. There have been no features, but quotations, while soft, have been fairly steady. Prime Western for early delivery and for shipment into July is quoted at 7.95c., St. Louis, or 8.35c., New York, with very little interest either by producers or consumers. The effect of the railroad demoralization is still apparent, though shipments out of St. Louis are reported as nearly normal. There is no desire by producers to sell at present levels and they are confident of higher prices later. The British market still is a factor, though sales by exporters for re-purchases on the other side have diminished.
